Asa Gray.

THE whole civilized world is mourning the death of Asa Gray with a depth of feeling and appreciation perhaps never accorded before to a scholar and man of science.

To the editors of this Journal the loss at the very outset of their labors is serious indeed. They lose a wise and sympathetic adviser of great experience and mature judgment to whom they could always have turned with entire freedom and in perfect confidence; and they lose a contributor whose vast stores of knowledge and graceful pen might, it was reasonable to hope, have long enriched their columns.

The career of Asa Gray is interesting from many points of view. It is the story of the life of a man born in humble circumstances, without the advantages of early education, without inherited genius—for there is no trace in his yeoman ancestry of any germ of intellectual greatness—who succeeded in gaining through native intelligence, industry and force of character, a position in the very front rank of the scientific men of his age. Among the naturalists who, since Linnæus, have devoted their lives to the description and classification of plants, four or five stand out prominently in the character and importance of their work. In this little group Asa Gray has fairly won for himself a lasting position. But he was something more than a mere systematist. He showed himself capable of drawing broad philosophical conclusions from the dry facts he collected and elaborated with such untiring industry and zeal. This power of comprehensive generalization he showed in his paper upon the "Characters of Certain New Species of Plants Collected in Japan" by Charles Wright, published nearly thirty years ago. Here he first pointed out the extraordinary similarity between the Floras of Eastern North America and Japan, and then explained the peculiar distribution of plants through the northern hemisphere by tracing their

direct descent through geological eras from ancestors which flourished in the arctic regions down to the latest tertiary period. This paper was Professor Gray's most remarkable and interesting contribution to science. It at once raised him to high rank among philosophical naturalists and drew the attention of the whole scientific world to the Cambridge botanist.

Asa Gray did not devote himself to abstract science alone; he wrote as successfully for the student as for the professional naturalist. His long list of educational works have no equals in accuracy and in beauty and compactness of expression. They have had a remarkable influence upon the study of botany in this country during the half century which has elapsed since the first of the series appeared.

Botany, moreover, did not satisfy that wonderful intellect, which hard work only stimulated but did not weary, and one of Asa Gray's chief claims to distinction is the prominent and commanding position he took in the great intellectual and scientific struggle of modern times, in which, almost alone and single handed he bore in America the brunt of the disbelief in the Darwinian theory shared by most of the leading naturalists of the time.

But the crowning labor of Asa Gray's life was the preparation of a descriptive work upon the plants of North America. This great undertaking occupied his attention and much of his time during the last forty years of his life. Less fortunate than his greatest botanical contemporary, George Bentham, who turned from the last page of corrected proof of his work upon the genera of plants to the bed from which he was never to rise again, Asa Gray's great work is left unfinished. The two volumes of the "Synoptical Flora of North America" will keep his memory green, however, as long as the human race is interested in the study of plants.

But his botanical writings and his scientific fame are not the most valuable legacy which Asa Gray has left to the American people. More precious to us is the example of his life in this age of grasping materialism. It is a life that teaches how industry and unselfish devotion to learning can attain to the highest distinction and the most enduring fame. Great as were his intellectual gifts, Asa Gray was greatest in the simplicity of his character and in the beauty of his pure and stainless life.

It is with genuine regret that we read the announcement of the discontinuance of the *Gardener's Monthly*. It is like reading of the death of an old friend. Ever since we have been interested in the cultivation of flowers we have looked to the *Monthly* for inspiration and advice, and its pages have rarely been turned without finding the assistance we stood in need of. But, fortunately, the *Gardener's Monthly*, and its modest and accomplished editor, Mr. Thomas Meehan, were one and the same thing. It is Mr. Meehan's long editorial experience, high character, great learning and varied practical knowledge, which made the *Gardener's Monthly* what it was. These, we are happy to know, are not to be lost to us, as Mr. Meehan will, in a somewhat different field and with new associates, continue to delight and instruct the horticultural public.

Americans who visit Europe cannot fail to remark that in the parks and pleasure grounds of the Continent no coniferous tree is more graceful when young or more dignified at maturity than our White Pine. The notes of Dr. Mayr, of the Bavarian Forest Academy, in another column, testify that it holds a position of equal importance as a forest tree for economic planting. It thrives from Northern Germany to Lombardy, corresponding with a range of climate in this country from New England to Northern Georgia. It needs bright sunshine, however, and perhaps it is for lack of this that so few good specimens are seen in England. It was among the first of our trees to be introduced there, but it has been universally pronounced an indifferent grower.

The Forests of the White Mountains.

NEW HAMPSHIRE is not a peculiarly wealthy State, but it has some resources scarcely equaled by those of any of its sisters. The White Mountains, though worth little to the farmer, are a piece of real estate which yields a sure and abundant income by attracting tourists and their money; and this revenue is certain to increase, unless blind mismanagement interposes. The White Mountains are at present unique objects of attraction; but they may easily be spoiled, and the yearly tide of tourists will thus be turned towards other points of interest whose owners have had more sense and foresight.

These mountains owe three-fourths of their charms to the primeval forest that still covers them. Speculators have their eyes on it, and if they are permitted to work their will the State will find a most productive piece of property sadly fallen in value. If the mountains are robbed of their forests they will become like some parts of the Pyrenees, which, though much higher, are without interest, because they have been stripped bare.

The forests of the White Mountains have a considerable commercial value, and this value need not be sacrificed. When lumber speculators get possession of forests they generally cut down all the trees and strip the land at once, with an eye to immediate profit. The more conservative, and, in the end, the more profitable management, consists in selecting and cutting out the valuable timber when it has matured, leaving the younger growth for future use. This process is not very harmful to the landscape. It is practiced extensively in Maine, where the art of managing forests with a view to profit is better understood than elsewhere in this country. A fair amount of good timber may thus be drawn from the White Mountains, without impairing their value as the permanent source of a vastly greater income from the attraction they will offer to an increasing influx of tourists. At the same time the streams flowing from them, and especially the Pemigewasset, a main source of the Merrimac, will be saved from the alternate droughts and freshets to which all streams are exposed that take their rise in mountains denuded of forests. The subject is one of the last importance to the mill owners along these rivers.

F. Parkman.

Landscape Gardening.—A Definition.

SOME of the Fine Arts appeal to the ear, others to the eye. The latter are the Arts of Design, and they are usually named as three—Architecture, Sculpture and Painting. A man who practices one of these in any of its branches is an artist; other men who work with forms and colors are at the best but artisans. This is the popular belief. But in fact there is a fourth art which has a right to be rated with the others, which is as fine as the finest, and which demands as much of its professors in the way of creative power and executive skill as the most difficult. This is the art whose purpose it is to create beautiful compositions upon the surface of the ground.

The mere statement of its purpose is sufficient to establish its rank. It is the effort to produce organic beauty—to compose a beautiful whole with a number of related parts—which makes a man an artist; neither the production of a merely useful organism nor of a single beautiful detail suffices. A clearly told story or a single beautiful word is not a work of art—only a story told in beautifully connected words. A solidly and conveniently built house, if it is nothing more, is not a work of architecture, nor is an isolated stone, however lovely in shape and surface. A delightful tint, a graceful line, does not make a picture; and though the painter may reproduce ugly models he must put some kind of beauty into the reproduction if it is to be esteemed above any other manufactured article—if not beauty of form, then beauty of color or of meaning or at least of execution. Similarly, when a man

disposes the surface of the soil with an eye to crops alone he is an agriculturist; when he grows plants for their beauty as isolated objects he is a horticulturist; but when he disposes ground and plants together to produce organic beauty of effect, he is an artist with the best.

Yet though all the fine arts are thus akin in general purpose they differ each from each in many ways. And in the radical differences which exist between the landscape-gardener's and all the others we find some reasons why its affinity with them is so commonly ignored. One difference is that it uses the same materials as nature herself. In what is called "natural" gardening it uses them to produce effects which under fortunate conditions nature might produce without man's aid. Then, the better the result, the less likely it is to be recognized as an artificial—artistic—result. The more perfectly the artist attains his aim, the more likely we are to forget that he has been at work. In "formal" gardening, on the other hand, nature's materials are disposed and treated in frankly unnatural ways; and then—as a more or less intelligent love for natural beauty is very common to-day, and an intelligent eye for art is rare—the artist's work is apt to be resented as an impertinence, denied its right to its name, called a mere contorting and disfiguring of his materials.

Again, the landscape-gardener's art differs from all others in the unstable character of its productions. When surfaces are modeled and plants arranged, nature and the artist must work a long time together before the true result appears; and when once it has revealed itself, day to day attention will be forever needed to preserve it from the deforming effects of time. It is easy to see how often neglect or interference must work havoc with the best intentions, how often the passage of years must travesty or destroy the best results, how rare must be the cases in which a work of landscape art really does justice to its creator.

Still another thing which affects popular recognition of the art as such is our lack of clearly understood terms by which to speak of it and of those who practice it. "Gardens" once meant pleasure-grounds of every kind and "gardener" then had an adequately artistic sound. But as the significance of the one term has been gradually specialized, so the other has gradually come to denote a mere grower of plants. "Landscape gardener" was a title first used by the artists of the eighteenth century to mark the new tendency which they represented—the search for "natural" as opposed to "formal" beauty; and it seemed to them to need an apology as savoring, perhaps, of grandiloquence or conceit. But as taste declined in England it was assumed by men who had not the slightest right, judged either by their aims or by their results, to be considered artists; and to-day it is fallen into such disesteem that it is often replaced by "landscape architect." This title has French usage to support it and is in many respects a good one. But its correlative—"landscape architecture"—is unsatisfactory; and so, on the other hand, is "landscape artist," though "landscape art" is an excellent generic term. Perhaps the best we can do is to keep to "landscape gardener," and try to remember that it ought always to mean an artist and an artist only.

M. G. van Rensselaer.

Floriculture in the United States.

AT the beginning of the present century, it is not probable that there were 100 florists in the United States, and their combined green-house structures could not have exceeded 50,000 square feet of glass. There are now more than 10,000 florists distributed through every State and Territory in the Union and estimating 5,000 square feet of glass to each, the total area would be 50,000,000 feet, or about 1,000 acres of green-houses. The value of the bare structures, with heating apparatus, at 60 cents per square foot would be \$30,000,000, while the stock of plants grown in them would not be less than

twice that sum. The present rate of growth in the business is about 25% per annum, which proves that it is keeping well abreast of our most flourishing industries.

The business, too, is conducted by a better class of men. No longer than thirty years ago it was rare to find any other than a foreigner engaged in commercial floriculture. These men had usually been private gardeners, who were mostly uneducated, and without business habits. But to-day, the men of this calling compare favorably in intelligence and business capacity with any mercantile class.

Floriculture has attained such importance that it has taken its place as a regular branch of study in some of our agricultural colleges. Of late years, too, scores of young men in all parts of the country have been apprenticing themselves to the large establishments near the cities, and already some of these have achieved a high standing; for the training so received by a lad from sixteen to twenty, better fits him for the business here than ten years of European experience, because much of what is learned there would prove worse than useless here. The English or German florist has here to contend with unfamiliar conditions of climate and a manner of doing business that is novel to him. Again he has been trained to more deliberate methods of working, and when I told the story a few years ago of a workman who had potted 10,000 cuttings in two inch pots in ten consecutive hours, it was stigmatized in nearly every horticultural magazine in Europe as a piece of American bragging. As a matter of fact this same workman two years later, potted 11,500 plants in ten hours, and since then several other workmen have potted plants at the rate of a thousand per hour all day long.

Old world conservatism is slow to adopt improvements. The practice of heating by low pressure steam will save in labor, coal and construction one-fifth of the expense by old methods, and nearly all the large green-house establishments in this country, whether private or commercial, have been for some years furnished with the best apparatus. But when visiting London, Edinburgh and Paris in 1885, I neither saw nor heard of a single case where steam had been used for green-house heating. The stress of competition here has developed enterprise, encouraged invention and driven us to rapid and prudent practice, so that while labor costs at least twice as much as it does in Europe, our prices both at wholesale and retail, are lower. And yet I am not aware that American florists complain that their profits compare unfavorably with those of their brethren over the sea.

Commercial floriculture includes two distinct branches, one for the production of flowers and the other for the production of plants. During the past twenty years the growth in the flower department of the business has outstripped the growth of the plant department. The increase in the sale of Rosebuds in winter is especially noteworthy. At the present time it is safe to say that one-third of the entire glass structures in the United States are used for this purpose; many large growers having from two to three acres in houses devoted to Roses alone, such erections costing from \$50,000 to \$100,000 each, according to the style in which they are built.

More cut flowers are used for decoration in the United States than in any other country, and it is probable that there are more flowers sold in New York than in London with a population four times as great. In London and Paris, however, nearly every door-yard and window of city and suburb show the householder's love for plants, while with us, particularly in the vicinity of New York (Philadelphia and Boston are better), the use of living plants for home decoration is far less general.

There are fashions in flowers, and they continually change. Thirty years ago thousands of Camellia flowers were retailed in the holiday season for \$1 each, while Rosebuds would not bring a dime. Now, many of the fancy Roses sell at \$1 each, while Camellia flowers go begging at ten cents. The Chrysanthemum is now rivaling the Rose, as well it may, and no doubt every decade will see

the rise and fall of some floral favorite. But beneath these flitting fancies is the substantial and unchanging love of flowers that seems to be an original instinct in man, and one that grows in strength with growing refinement. Fashion may now and again condemn one flower or another, but the fashion of neglecting flowers altogether will never prevail, and we may safely look forward in the expectation of an ever increasing interest and demand, steady improvement in methods of cultivation, and to new and attractive developments in form, color and fragrance.

Peter Henderson.

How to Make a Lawn.

“A SMOOTH, closely shaven surface of grass is by far the most essential element of beauty on the grounds of a suburban home.” This is the language of Mr. F. J. Scott, and it is equally true of other than suburban grounds. A good lawn then is worth working for, and if it have a substantial foundation, it will endure for generations, and improve with age.

We take it for granted that the drainage is thorough, for no one would build a dwelling on water soaked land. No labor should be spared in making the soil deep, rich and fine in the full import of the words, as this is the stock from which future dividends of joy and satisfaction are to be drawn. Before grading, one should read that chapter of Downing's on “The Beauty in Ground.” This will warn against terracing or leveling the whole surface, and insure a contour with “gentle curves and undulations,” which is essential to the best effects.

If the novice has read much of the conflicting advice in books and catalogues, he is probably in a state of bewilderment as to the kind of seed to sow. And when that point is settled it is really a difficult task to secure pure and living seeds of just such species as one orders. Rarely does either seller or buyer know the grasses called for, especially the finer and rarer sorts; and more rarely still does either know their seeds. The only safe way is to have the seeds tested by an expert. Mr. J. B. Olcott, in a racy article in the “Report of the Connecticut Board of Agriculture for 1886,” says, “Fifteen years ago nice people were often sowing timothy, red top and clover for door-yards, and failing wretchedly with lawn-making, while seedsmen and gardeners even disputed the identity of our June grass and Kentucky blue-grass.”

We have passed beyond that stage of ignorance, however; and to the question what shall we sow, Mr. Olcott replies: “Rhode Island bent and Kentucky blue-grass are their foolish trade names, for they belong no more to Kentucky or Rhode Island than to other Northern States. Two sorts of fine *Agrostis* are honestly sold under the trade name of Rhode Island bent, and, as trade goes, we may consider ourselves lucky if we get even the coarser one. The finest—a little the finest—*Agrostis canina*—is a rather rare, valuable, and elegant grass, which should be much better known by grass farmers, as well as gardeners, than it is. These are both good lawn as well as pasture grasses.” The grass usually sold as Rhode Island bent is *Agrostis vulgaris*, the smaller red top of the East and of Europe. This makes an excellent lawn. *Agrostis canina* has a short, slender, projecting awn from one of the glumes; *Agrostis vulgaris* lacks this projecting awn. In neither case have we in mind what Michigan and New York people call red top. This is a tall, coarse native grass often quite abundant on low lands, botanically *Agrostis alba*.

Sow small red top or Rhode Island bent, and June grass (Kentucky blue grass, if you prefer that name), *Poa pratensis*. If in the chaff, sow in any proportion you fancy, and in any quantity up to four bushels per acre. If evenly sown, less will answer, but the thicker it is sown the sooner the ground will be covered with fine green grass. We can add nothing else that will improve this mixture, and either alone is about as good as both. A little white clover or sweet vernal grass or sheep's fescue may be added, if you fancy them, but they will not improve the appearance of the lawn. Roll the ground after seeding. Sow the seeds in September or in March or April, and under no circumstance yield to the advice to sow a little oats or rye to “protect the young grass.” Instead of protecting, they will rob the slender grasses of what they most need.

Now wait a little. Do not be discouraged if some ugly weeds get the start of the numerous green hairs which slowly follow. As soon as there is anything to be cut, of weeds or grass, mow closely, and mow often, so that nothing need be raked from the ground. As Olcott puts it, “Leave one crop where it belongs

for home consumption. The rains will wash the soluble substance of the wilted grass into the earth to feed the growing roots." During succeeding summers as the years roll on, the lawn should be perpetually enriched by the leaching of the short leaves as they are often mown. Neither leave a very short growth nor a very heavy growth for winter. Experience alone must guide the owner. If cut too closely, some of it may be killed or start too late in spring; if left too high during winter, the dead long grass will be hard to cut in spring and leave the stubble unsightly. After passing through one winter the annual weeds will have perished and leave the grass to take the lead. Perennial weeds should be faithfully dug out or destroyed in some way.

Every year, add a top dressing of some commercial fertilizer or a little finely pulverized compost which may be brushed in. No one will disfigure his front yard with coarse manure spread on the lawn for five months of the year.

If well made, a lawn will be a perpetual delight as long as the proprietor lives, but if the soil is thin and poor, or if the coarser grasses and clovers are sown instead of those named, he will be much perplexed, and will very likely try some expensive experiments, and at last plow up, properly fit the land and begin over again. This will make the cost and annoyance much greater than at first, because the trees and shrubs have already filled many portions of the soil. A small piece, well made and well kept, will give more satisfaction than a larger plot of inferior turf.

W. J. Beal.

Horticultural Exhibitions in London.

At a late meeting of the floral committee of the Royal Horticultural Society at South Kensington among many novelties was a group of seedling bulbous *Calanthes* from the garden of Sir Trevor Lawrence, who has devoted much attention to these plants and has raised some interesting hybrids. About twenty kinds were shown, ranging in color from pure white to deep crimson. The only one selected for a first-class certificate was *C. sanguinaria*, with flowers similar in size and shape to those of *C. Veitchii*, but of an intensely deep crimson. It is the finest yet raised, surpassing *C. Sedeni*, hitherto unequalled for richness of color. The pick of all these seedlings would be *C. sanguinaria*, *C. Veitchii splendens*, *C. lactea*, *C. nivea*, and *C. porphyrea*. The adjectives well describe the different tints of each, and they will be universally popular when once they find their way into commerce.

Cypripedium Leeantum maculatum, also shown by Sir Trevor Lawrence, is a novelty of sterling merit. The original *C. Leeantum*, which is a cross between *C. Spicerianum* and *C. insigne Maulei*, is very handsome, but this variety eclipses it, the dorsal sepal of the flower being quite two and one-half inches broad, almost entirely white, heavily and copiously spotted with purple. It surpasses also *C. Leeantum superbum*, which commands such high prices. I saw a small plant sold at auction lately for fifteen guineas and the nursery price is much higher.

Lælia anceps Schröderæ is the latest addition to the now very numerous list of varieties of the popular *L. anceps*. This new form, to which the committee with one accord gave a first class certificate, surpasses in my opinion all the colored varieties, with the possible exception of the true old *Barkeri*. The flowers are of the average size and ordinary form. The sepals are rose pink, the broad sepals very light, almost white in fact, while the labellum is of the deepest and richest velvety crimson imaginable. The golden tipped crest is a veritable beauty spot, and the pale petals act like a foil to show off the splendor of the lip.

Two new Ferns of much promise received first class certificates. One named *Pteris Claphamensis* is a chance seedling and was found growing among a lot of other sporelings in the garden of a London amateur. As it partakes of the characters of both *P. tremula* and *P. serrulata*, old and well known ferns, it is supposed to be a natural cross between these. The new plant is of tufted growth, with a dense mass of fronds about six inches long, elegantly cut and gracefully recurved on all sides of the pot. It is looked upon by specialists as just the sort of plant that will take in the market. The other certificated fern, *Adiantum Reginae*, is a good deal like *A. Victoria* and is supposed to be a sport from it. But *A. Reginae*, while it has broad pinnæ of a rich emerald green like *A. Victoria*, has fronds from nine to twelve inches long, giving it a lighter and more elegant appearance. I don't know that the *Victoria* Maidenhair is grown in America yet, but I am sure those who do floral decorating will welcome it as well as the newer *A. Reginae*. A third Maidenhair of a similar character is *A. rhodophyllum* and these form a trio that will become the standard

kinds for decorating. The young fronds of all three are of a beautiful coppery red tint, the contrast of which with the emerald green of the mature fronds is quite charming. They are warm green-house ferns and of easy culture, and are supposed to be hybrid forms of the old *A. scutum*.

Nerine Mansellii, a new variety of the Guernsey Lily, was one of the loveliest flowers at the show. From the common Guernsey Lily it differs only in color of the flowers. These have crimped-edged petals of clear rose tints; and the umbel of flowers is fully six inches across, borne on a stalk eighteen inches high. These Guernsey Lilies have of recent years come into prominence in English gardens since so many beautiful varieties have been raised, and as they flower from September onward to Christmas they are found to be indispensable for the green-house, and indoor decoration. The old *N. Fothergillii major*, with vivid scarlet-crimson flowers and crystalline cells in the petals which sparkle in the sunlight like myriads of tiny rubies, remains a favorite among amateurs. Baron Schroeder, who has the finest collection in Europe, grows this one only in quantity. An entire house is filled with them, and when hundreds of spikes are in bloom at once, the display is singularly brilliant.

A New Vegetable, a Japanese plant called Choro-Gi, belonging to the Sage family, was exhibited. Its botanical name is *Stachys tuberosa* and it was introduced first to Europe by the Vilmorins of Paris under the name of *Crosnes du Japon*. The edible part of the plant is the tubers, which are produced in abundance on the tips of the wiry fibrous roots. These are one and a half inches long, pointed at both ends, and have prominent raised rings. When washed they are as white as celery and when eaten raw taste somewhat like Jerusalem artichokes, but when cooked are quite soft and possess the distinct flavor of boiled chestnuts. A dish of these tubers when cooked look like a mass of large caterpillars, but the Committee pronounced them excellent, and no doubt this vegetable will now receive attention from some of our enterprising seedsmen and may become a fashionable vegetable because new and unlike any common kind. The tubers were shown now for the first time in this country by Sir Henry Thompson, the eminent surgeon. The plant is herbaceous, dying down annually leaving the tubers, which multiply very rapidly. They can be dug at any time of the year, which is an advantage. The plant is perfectly hardy here and would no doubt be so in the United States, as it remains underground in winter. [A figure of this plant with the tubers appeared in the *Gardener's Chronicle*, January 7th, 1888.—Ed.]

Phalænopsis F. L. Ames, a hybrid moth orchid, the result of intercrossing *P. grandiflora* of Lindley with *P. intermedia Portei* (itself a natural hybrid between the little *P. rosea* and *P. amabilis*), was shown at a later exhibition. The new hybrid is very beautiful. It has the same purplish green leaves as *P. amabilis*, but much narrower. The flower spikes are produced in the same way as those of *P. grandiflora*, and the flowers in form and size resemble those of that species, but the coloring of the labellum is more like that of its other parent. The sepals and petals are pure white, the latter being broadest at the lips. The labellum resembles that of *P. intermedia*, being three-lobed, the lateral lobes are erect, magenta purple in color and freckled. The middle or triangular lobe is of the same color as the lateral lobes, but pencilled with longitudinal lines of crimson, flushed with orange, and with the terminal cirrhi of a clear magenta. The column is pink, and the crest is adorned with rosy speckles. The Floral Committee unanimously awarded a first-class certificate of merit to the plant.

A New *Lælia* named *L. Gouldiana* has had an eventful history. The representative of Messrs. Sander, of St. Albans, the great orchid importers, while traveling in America saw it blooming in New York, in the collection of Messrs. Siebrecht & Wadley, and noting its distinctness and beauty bought the stock of it. The same week another new *Lælia* flowered in England and was sent up to one of the London auction rooms for sale. As it so answered the description of the American novelty which Messrs. Sander had just secured it was bought for the St. Albans collection, and now it turns out that the English novelty and the American novelty are one and the same thing, and a comparison of dates shows that they flowered on the same day, although in different hemispheres. As, however, it was first discovered in the United States, it is intended to call it an American orchid, and that is why Mr. Jay Gould has his name attached to it. In bulb and leaf the novelty closely resembles *L. albida*, and in flower both *L. anceps* and *L. autumnalis*. The flowers are as large as those of an average form of *L. anceps*, the sepals are rather narrow, the petals as broad as those of *L.*

Fig. 1.—Chrysanthemum—Mrs. Alpheus Hardy.

anceps Dawsoni, and both petals and sepals are of a deep rose pink, intensified at the tips as if the color had collected there and was dripping out. The tip is in form between that of *L. anceps* and *L. autumnalis* and has the prominent ridges of the latter, while the color is a rich purple crimson. The black viscid pubescence, always seen on the ovary of *L. autumnalis*, is present on that of *L. Gouldiana*. The plants I saw in the orchid nursery at St. Albans lately, bore several spikes, some having three or four flowers. Those who have seen it are puzzled about its origin, some considering it a hybrid between *L. anceps* and *L. autumnalis*, others consider it a distinct species and to the latter opinion I am inclined. Whatever its origin may be, it is certain we have a charming addition to midwinter flowering orchids.

W. Goldring.

London, February 1st,

A New Departure in Chrysanthemums.

THE Chrysanthemum of which the figure gives a good representation is one of a collection of some thirty varieties lately sent from Japan to the lady for whom it has been named. Mrs. Alpheus Hardy of Boston, by a young Japanese once a protégé of hers, but now returned as a teacher to his native country. As may be seen, it is quite distinct from any variety known in this country or Europe, and the Japanese botanist Miyabe, who saw it at Cambridge, pronounces it a radical departure from any with which he is acquainted.

The photograph from which the engraving was made was taken just as the petals had begun to fall back from the centre, showing to good advantage the peculiarities of the variety.

The flower is of pure white, with the firm, long and broad petals strongly incurved at the extremities. Upon the back of

outer surface of this incurved portion will be found, in the form of quite prominent hairs, the peculiarity which makes this variety unique.

These hairs upon close examination are found to be a glandular outgrowth of the epidermis of the petals, multicellular in structure and with a minute drop of a yellow resinous substance at the tip. The cells at first conform to the wavy character of those of the epidermis, but gradually become prismatic with straight walls, as shown in the engraving of one of the hairs, which was made from a drawing furnished by Miss Grace Cooley, of the Department of Botany at Wellesley College, who made a microscopic investigation of them.

This is one of those surprises that occasionally make their appearance from Japan. Possibly it is a chance seedling; but since one or two other specimens in the collection are striking in form, and others are distinguished for depth and purity of color, it is more probable that the best of them have been developed by careful selection.

This *Chrysanthemum* was exhibited at the Boston Chrysanthemum Show last December by Edwin Fewkes & Son of Newton Highlands, Mass.

Fig. 2.—Hair from Petal of *Chrysanthemum*, much enlarged. *a*—resin drop. *b*—epidermis of petal with wavy cells.

A. H. Fewkes.

New Plants from Afghanistan.

Arnebia cornuta.—This is a charming novelty, an annual, native of Afghanistan. The little seedling with lancet-like hairy, dark green leaves, becomes presently a widely branching plant two feet in diameter and one and one-half feet high. Each branch and branchlet is terminated by a lengthening raceme of flowers. These are in form somewhat like those of an autumnal Phlox, of a beautiful deep golden yellow color, adorned and brightened up by five velvety black blotches. These blotches soon become coffee brown and lose more and more their color, until after three days they have entirely disappeared. During several months the plant is very showy, the fading flowers being constantly replaced by fresh expanding ones. Sown in April in the open border, it needs no care but to be thinned out and kept free from weeds. It must, however, have some soil which does not contain fresh manure.

Delphinium Zalil.—This, also, is a native of Afghanistan, but its character, whether a biennial or perennial, is not yet ascertained. The Afghans call it Zalil and the plant or root is used for dyeing purposes. Some years ago we only knew blue, white and purple larkspurs, and then California added two species with scarlet flowers. The above is of a beautiful sulphur yellow, and, all in all, it is a plant of remarkable beauty. From a rosette of much and deeply divided leaves, rises a branched flower stem to about two feet; each branch and branchlet ending in a beautiful spike of flowers each of about an inch across and the whole spike showing all its flowers open at once. It is likely to become a first rate standard plant of our gardens. To have it in flower the very first year it must be sown very early, say in January, in seed pans, and transplanted later, when it will flower from the end of May until the end of July. Moreover, it can be sown during spring and summer in the open air to flower the following year. It is quite hardy here.

Baden-Baden.

Max Leichtlin.

Iris tenuis.*

THIS pretty delicate species of *Iris*, Fig. 3, is a native of the Cascade Mountains of Northern Oregon. Its long branching rootstocks are scarcely more than a line in thickness, sending up sterile leafy shoots and slender stems about a foot high. The leaves are thin and pale green, rather taller than the stems, sword-shaped and half an inch broad or more. The leaves of the stem are bract-like and distant, the upper one or two subtending slender peduncles. The spathes are short, very thin

**I. TENUIS*, Watson, *Proc. Amer. Acad.*, xvii. 380. Rootstock elongated, very slender (a line thick); leaves thin, ensiform, about equaling the stems, four to eight lines broad; stems scarcely a foot high, 2-3-flowered, with two or three bract-like leaves two or three inches long; lateral peduncles very slender, as long as the bracts; spathes scarious, an inch long; pedicels solitary, very short; flowers small, white marked with yellow and purple; tube two or three lines long; segments oblong-spatulate, the sepals spreading, one and one-half inches long, the petals shorter and emarginate; anthers as long as the filaments; styles with narrow entire crests; capsule oblong-ovate, obtuse, nine lines long

and scarious, and enclose the bases of their rather small solitary flowers, which are "white, lightly striped and blotched with yellow and purple." The sepals and petals are oblong-spatulate, from a short tube, the sepals spreading, the shorter petals erect and notched.

The peculiar habitat of this species doubtless accounts in good measure for its slender habit and mode of growth. Mr. L. F. Henderson, of Portland, Oregon, who discovered it in 1881, near a branch of the Clackamas River called Eagle Creek, about thirty miles from Portland, reports it as growing in the fir forests in broad mats, its very long rootstocks running along near the surface of the ground, just covered by moss or partly decayed fir-needles, with a light addition of soil. This also would indicate the need of special care and treatment in its cultivation. In May, 1884, Mr. Henderson took great pains to procure roots for the Botanic Garden at Cambridge, which were received in good order, but which did not survive the next winter. If taken up, however, later in the season or very early in the spring, it is probable that with due attention to soil and shade there would be little trouble in cultivating it successfully. The accompanying figure is from a drawing by Mr. C. E. Faxon.

Sereno Watson.

Hardy Shrubs for Forcing.

SHRUBS for forcing should consist of early blooming kinds only. The plants should be stocky, young and healthy, well-budded and well-ripened, and in order to have first-class stock they should be grown expressly for forcing. For cut flower purposes only, we can lift large plants of Lilacs, Snowballs, Deutzias, Mock oranges and the like with all the ball of roots we can get to them and plant at once in forcing-houses. But this should not be done before New Year's. We should prepare for smaller plants some months ahead of forcing time, say in the preceding April or August, by lifting them and planting in small pots, tubs or boxes as can conveniently contain their roots, and we should encourage them to root well before winter sets in. Keep them out of doors and plunged till after the leaves drop off; then either mulch them where they are or bring them into a pit, shed or cool cellar, where there shall be no fear of their getting dry, or of having the roots fastened in by frost. Introduce them into the green-house in succession; into a cool green-house at first for a few weeks, then as they begin to start, into a warmer one. From the time they are brought into the green-house till the flowers begin to open give a sprinkling overhead twice a day with tepid water. When they have done blooming, if worth keeping over for another time, remove them to a cool house and thus gradually harden them off, then plant them out in the garden in May, and give them two years' rest.

Shrubs to be forced for their cut flowers only should consist of such kinds as have flowers that look well and keep well after being cut. Among these are *Deutzia gracilis*, common Lilacs of various colors, *Staphyllea Colchica*, *Spiraea Cantonensis* (*Reevesii*) single and double, the Guelder Rose, the Japanese Snowball and *Azalea mollis*. To these may be added some of the lovely double-flowering and Chinese apples, whose snowy or crimson-tinted buds and leafy twigs are very pretty. The several double-flowered forms of *Prunus triloba* are also desirable, but a healthy stock is hard to get. *Andromeda floribunda* and *A. Japonica* set their flower buds the previous summer for the next year's flowers, and are, therefore, like the *Laurestinus*, easily forced into bloom after New Year's. Hardy and half-hardy Rhododendrons with very little forcing may be had in bloom from March.

In addition to the above, for conservatory decoration we may introduce all manner of hardy shrubs. Double flowering peach and cherry trees are easily forced and showy while they last. Clumps of *Pyrus arbutifolia* can easily be had in bloom in March, when their abundance of deep green leaves is an additional charm to their profusion of hawthorn-like flowers. The Chinese *Xanthoceras* is extremely copious and showy, but of brief duration and ill-fitted for cutting. Bushes of yellow Broom and double-flowering golden Furze can easily be had after January. *Fasminum nudiflorum* may be had in bloom from November till April, and Forsythia from January. They look well when trained up to pillars. The early-flowering Clematises may be used to capital advantage in the same way, from February onward. Although the Mahonias flower well, their foliage at blooming time is not always comely. Out-of-doors the American Red-bud makes a handsomer tree than does the Japanese one; but the latter is preferable for green-house work, as the flowers are bright and the smallest plants bloom. The Chinese *Wistaria* blooms as well in the

green-house as it does outside; indeed, if we introduce some branches of an out-door plant into the green-house, we can have it in bloom two months ahead of the balance of the vine still left out-of-doors. Here-about we grow Wistarias as standards, and they bloom magnificently. What a sight a big standard wistaria in the green-house in February would be! Among other shrubs may be mentioned Shadbush, African Tamarix, Daphne of sorts and Exochorda. We have also a good many barely hardy plants that may be wintered well in a cellar or cold pit, and forced into bloom in early spring. Among these are Japanese Privet, Pittosporum, Raphiolepis, Hydrangeas and the like.

And for conservatory decoration we can also use with excellent advantage some of our fine-leaved shrubs, for instance our lovely Japanese Maples and variegated Box Elder.

Glen Cove, N. Y. Wm. Falconer.

Plant Notes.

A Half-hardy Begonia.—When botanizing last September upon the Cordilleras of North Mexico some two hundred miles south of the United States Boundary, I found growing in black mould of shaded ledges—even in the thin humus of mossy rocks—at an elevation of 7,000 to 8,000 feet, a plant of striking beauty, which Mr. Sereno Watson identifies as *Begonia gracilis*, HBK., var. *Martiana*, A. DC. From a small tuberous root it sends up to a height of one to two feet a single crimson-tinted stem, which terminates in a long raceme of scarlet flowers, large for the genus and long enduring. The plant is still further embellished by clusters of scarlet gemmæ in the axils of its leaves. Mr. Watson writes: "It was in cultivation fifty years and more ago, but has probably been long ago lost. It appears to be the most northern species of the genus, and should be the most hardy." Certainly the earth freezes and snows fall in the high region, where it is at home.

Northern Limit of the Dahlia.—In the same district, and at the same elevation, I met with a purple flowered variety of *Dahlia coccinea*, Cav. It was growing in patches under oaks and pines in thin dry soil of summits of hills. In such exposed situations the roots must be subjected to some frost, as much certainly as under a light covering of leaves in a northern garden. The Dahlia has not before been reported, as I believe, from a latitude nearly so high. C. G. Pringle.

Ceanothus is a North American genus, represented in the Eastern States by New Jersey Tea, and Red Root (*C. Americanus* and *C. ovatus*), and in the

West and South-west by some thirty additional species. Several of these Pacific Coast species are quite handsome and well worthy of cultivation where they will thrive. Some of the more interesting of them are figured in different volumes of the *Botanical Magazine*, from plants grown at Kew, and I believe that the genus is held in considerable repute by French gardeners.

In a collection of plants made in Southern Oregon, last spring, by Mr. Thomas Howell, several specimens of *Ceanothus* occur which are pretty clearly hybrids between *C. cuneatus* and *C. prostratus*, two common species of the region. Some have the spreading habit of the latter, their flowers are of the bright blue color characteristic of that species, and borne on slender blue pedicels, in an umbel-like cluster. But while many of their leaves have the abrupt three-toothed apex of *C. prostratus*, all gradations can be found from this form to the spatulate, toothless leaves of *C. cuneatus*. Other specimens have the more rigid habit of the latter species, and their flowers are white or nearly so, on shorter pale pedicels, in usually smaller and denser clusters. On these plants the leaves are commonly those of *C. cuneatus*, but they pass into the truncated and toothed form proper to *C. prostratus*.

According to Focke (*Pflanzenmischlinge*, 1881, p. 99), the French cross one or more of the blue-flowered Pacific Coast species on the hardier New Jersey Tea, a practice that may perhaps be worthy of trial by American gardeners. Have any of the readers of GARDEN AND FOREST ever met with spontaneous hybrids?

W. Trelease.

Wire Netting for Tree Guards.

—On some of the street trees of Washington heavy galvanized wire netting is used to protect the bark from injury by horses. It is the same material that is used for enclosing poultry yards. It comes in strips five or six feet wide, and may be cut to any length required by the size of the tree. The edges are held in place by bending together the cut ends of the wires, and the whole is sustained by staples over the heavy wires at the top and bottom. This guard appears to be an effective protection and is less unsightly than any other of which I know, in fact it can hardly be distinguished at the distance of a few rods. It is certainly an improvement on the plan of white-washing

the trunks, which has been extensively practiced here since the old guards were removed.

Artificial Water.

ONE of the most difficult parts of a landscape gardener's work is the treatment of what our grandfathers called "pieces of water" in scenes where a purely natural effect is desired. The task is especially hard when the stream, pond or lake has been artificially formed; for then Nature's processes must be simulated not only in the planting but in the shaping of the shores. Our illustration partially reveals a successful effort of this sort—a pond on a country-seat near Boston.

It was formed by excavating a piece of swamp and damming a small stream which flowed through it. In the distance towards the right the land lies low by the water and gradually rises as it recedes. Opposite us it forms little wooded promontories with grassy stretches between. Where we stand it is higher, and beyond the limits of the picture to the left it forms

suited to their place and in harmony with each other; and all the contours of the shore are gently modulated and softly connected with the water by luxuriant growths of water plants. The witness of the eye alone would persuade us that Nature unassisted had achieved the whole result. But beauty of so suave and perfect a sort as this is never a natural product. Nature's beauty is wilder if only because it includes traces of mutation and decay which here are carefully effaced. Nature suggests the ideal beauty, and the artist realizes it by faithfully working out her suggestions. •

Some New Roses.

THE following list comprises most of the newer Roses that have been on trial to any extent in and about Philadelphia during the present winter:

A Piece of Artificial Water.

a high, steep bank rising to the lawn, on the further side of which stands the house. The base of these elevated banks and the promontories opposite are planted with thick masses of rhododendrons, which flourish superbly in the moist, peaty soil, protected, as they are, from drying winds by the trees and high ground. Near the low meadow a long stretch of shore is occupied by thickets of hardy azaleas. Beautiful at all seasons, the pond is most beautiful in June, when the rhododendrons are ablaze with crimson and purple and white, and when the yellow of the azalea-beds—discreetly separated from the rhododendrons by a great clump of low-growing willows—finds delicate continuation in the buttercups which fringe the daisied meadow. The lifted banks then afford particularly fortunate points of view; for as we look down upon the rhododendrons, we see the opposite shore and the water with its rich reflected colors as over the edge of a splendid frame. No accent of artificiality disturbs the eye despite the unwonted profusion of bloom and variety of color. All the plants are

Puritan (H. T.) is one of Mr. Henry Bennett's seedlings, and perhaps excites more interest than any other. It is a cross between Mabel Morrison and Devoniensis, creamy white in color and a perpetual bloomer. Its flowers have not opened satisfactorily this winter. The general opinion seems to be that it requires more heat than is needed for other forcing varieties. Further trial will be required to establish its merit.

Meteor (H. T., Bennett.)—Some cultivators will not agree with me in classing this among hybrid Teas. In its manner of growth it resembles some Tea Roses, but its coloring and scanty production of buds in winter are indications that there is Hybrid Remontant blood in it. It retains its crimson color after being cut longer than any Rose we have, and rarely shows a tendency to become purple with age, as other varieties of this color are apt to do. For summer blooming under glass it will prove satisfactory. In winter its coloring is a rich velvety crimson, but as the sun gets stronger it assumes a more lively shade.

Mrs. John Laing (H. R., Bennett) is a seedling from Francois Michelon, which it somewhat resembles in habit of growth and color of flower. It is a free bloomer out-of-doors in summer and forces readily in winter. Blooms of it have been offered for sale in the stores here since the first week in December. It is a soft shade of pink in color, with a delicate lilac tint. It promises to become a general favorite, as in addition to the qualities referred to, it is a free autumnal bloomer outside. For forcing it will be tried extensively next winter.

Princess Beatrice (T., Bennett) was distributed for the first time in this country last autumn, but has so far been a disappointment in this city. But some lots arrived from Europe too late and misfortunes befell others, so that the trial can hardly be counted decisive, and we should not hastily condemn it. Some have admired it for its resemblance, in form of flower, to a Madame Cuisin, but its color is not just what we need. In shade it somewhat resembles Sunset, but is not so effective. It may, however, improve under cultivation, as some other Roses have done; so far as I know it has not been tried out-of-doors.

Papa Gontier (H. B., Nabonnaud)—This, though not properly a new rose, is on trial for the first time in this city. It has become a great favorite with growers, retailers and purchasers. In habit it is robust and free blooming, and in coloring, though similar to Bon Silene, is much deeper or darker. There seems to be a doubt in some quarters as to whether it blooms as freely as Bon Silene; personally, I think there is not much difference between the two. Gontier is a good Rose for out-door planting.

Edwin Lonsdale.

Two Ferns and their Treatment.

Adiantum Farleyense.—This beautiful Maidenhair is supposed to be a subfertile, plumose form of *A. tenerum*, which much resembles it, especially in a young state. For decorative purposes it is almost unrivaled, whether used in pots or for trimming baskets of flowers or bouquets. It prefers a warm, moist house and delights in abundant water. We find it does best when potted firmly in a compost of two parts loam to one of peat, and with a good sprinkling of sifted coalashes. In this compost it grows very strong, the fronds attaining a deeper green and lasting longer than when grown in peat. When the pots are filled with roots give weak liquid manure occasionally. This fern is propagated by dividing the roots and potting in small pots, which should be placed in the warmest house, where they soon make fine plants. Where it is grown expressly for cut fronds the best plan is to plant it out on a bench in about six inches of soil, taking care to give it plenty of water and heat, and it will grow like a weed.

Actinopteris radiata.—A charming little fern standing in a genus by itself. In form it resembles a miniature fan palm, growing about six inches in height. It is generally distributed throughout the East Indies. In cultivation it is generally looked upon as poor grower, but with us it grows as freely as any fern we have. We grow a lot to mix in with Orchids, as they do not crowd at all. We pot in a compost of equal parts loam and peat with a few ashes to keep it open, and grow in the warmest house, giving at all times abundance of water both at root and overhead. It grows very freely from spores, and will make good specimens in less than a year. It is an excellent Fern for small baskets.

F. Goldring.

Timely Hints About Bulbs.

SPRING flowering bulbs in-doors, such as the Dutch Hyacinths, Tulips and the many varieties of Narcissus, should now be coming rapidly into bloom. Some care is required to get well developed specimens. When first brought in from cold frames or wherever they have been stored to make roots, do not expose them either to direct sunlight or excessive heat.

A temperature of not more than fifty-five degrees at night is warm enough for the first ten days, and afterwards, if they show signs of vigorous growth and are required for any particular occasion, they may be kept ten degrees warmer. It is more important that they be not exposed to too much light than to too much heat.

Half the short stemmed Tulips, dumpy Hyacinths and blind Narcissus we see in the green-houses and windows of amateurs are the result of excessive light when first brought into warm quarters. Where it is not possible to shade bulbs without interfering with other plants a simple and effective plan is to make funnels of paper large enough to stand inside each pot and six inches high. These may be left on the pots night and day from the time the plants are brought in until the flower spike has grown above the foliage; indeed, some of the very finest Hyacinths cannot be had in perfection without some

such treatment. Bulbous plants should never suffer for water when growing rapidly, yet on the other hand, they are easily ruined if allowed to become sodden.

When in flower a rather dry and cool temperature will preserve them the longest.

Of bulbs which flower in the summer and fall, Gloxinias and tuberous rooted Begonias are great favorites and easily managed. For early summer a few of each should be started at once—using sandy, friable soil. Six-inch pots, well drained, are large enough for the very largest bulbs, while for smaller even three-inch pots will answer. In a green-house there is no difficulty in finding just the place to start them. It must be snug, rather shady and not too warm. They can be well cared for, however, in a hot-bed or even a window, but some experience is necessary to make a success.

Lilies, in pots, whether *L. candidum* or *L. longiflorum* that are desired to be in flower by Easter, should now receive every attention—their condition should be that the flower buds can be easily felt in the leaf heads. A temperature of fifty-five to sixty-five at night should be maintained, giving abundance of air on bright sunny days to keep them stocky. Green fly is very troublesome at this stage, and nothing is more certain to destroy this pest than to dip the plants in tobacco water which, to be effective, should be the color of strong tea. Occasional waterings of weak liquid manure will be of considerable help if the pots are full of roots.

J. Thorpe.

Entomology.

Arsenical Poisons in the Orchard.

AS is well known, about fifty per cent. of the possible apple crop in the Western States is sacrificed each year to the codling moth, except in sections where orchardists combine to apply bands of straw around the trunks. But as is equally well known this is rather a troublesome remedy. At all events, in Illinois, Professor Forbes, in a bulletin lately issued from the office of the State Entomologist of Illinois, claims that the farmers of that State suffer an annual loss from the attacks of this single kind of insect of some two and three-quarters millions of dollars.

As the results of two years' experiments in spraying the trees with a solution of Paris green, only once or twice in early spring, before the young apples had drooped upon their stems, there was a saving of about seventy-five per cent. of the apples.

The Paris green mixture consisted of three-fourths of an ounce of the powder by weight, of a strength to contain 15.4 per cent. of metallic arsenic, simply stirred up in two and a half gallons of water. The tree was thoroughly sprayed with a hand force-pump, and with the deflector spray and solid jet-hose nozzle, manufactured in Lowell, Mass. The fluid was thrown in a fine mist-like spray, applied until the leaves began to drip.

The trees were sprayed in May and early in June while the apples were still very small. It seems to be of little use to employ this remedy later in the season, when later broods of the moth appear, since the poison takes effect only in case it reaches the surface of the apple between the lobes of the calyx, and it can only reach this place when the apple is very small and stands upright on its stem. It should be added that spraying "after the apples have begun to hang downward is unquestionably dangerous," since even heavy winds and violent rains are not sufficient to remove the poison from the fruit at this season.

At the New York Experimental Station last year a certain number of trees were sprayed three times with Paris green with the result that sixty-nine per cent. of the apples were saved.

It also seems that last year about half the damage that might have been done by the Plum weevil or curculio was prevented by the use of Paris green, which should be sprayed on the trees both early in the season, while the fruit is small, as well as later.

The cost of this Paris green application, when made on a large scale, with suitable apparatus, only once or twice a year, must, says Mr. Forbes, fall below an average of ten cents a tree.

The use of solutions of Paris green or of London purple in water, applied by spraying machines such as were invented and described in the reports of the national Department of Agriculture by the U. S. Entomologist and his assistants, have effected a revolution in remedies against orchard and forest insects. We expect to see them, in careful hands, tried with equal success in shrubberies, lawns and flower gardens.

A. S. Packard.

The Forest.

The White Pine in Europe.

THE White Pine was among the very first American trees which came to Europe, being planted in the year 1705 by Lord Weymouth on his grounds in Chelsea. From that date, the tree has been cultivated in Europe under the name of Weymouth Pine; in some mountain districts of northern Bavaria, where it has become a real forest tree, it is called Strobe, after the Latin name *Pinus strobus*. After general cultivation as an ornamental tree in parks this Pine began to be used in the forests on account of its hardiness and rapid growth, and it is now not only scattered through most of the forests of Europe, but covers in Germany alone an area of some 300 acres in a dense, pure forest. Some of these are groves 120 years old, and they yield a large proportion of the seed demanded by the increasing cultivation of the tree in Europe.

The White Pine has proved so valuable as a forest tree that it has partly overcome the prejudices which every foreign tree has to fight against. The tree is perfectly hardy, is not injured by long and severe freezing in winter, nor by untimely frosts in spring or autumn, which sometimes do great harm to native trees in Europe. On account of the softness of the leaves and the bark, it is much damaged by the nibbling of deer, but it heals quickly and throws up a new leader.

The young plant can endure being partly shaded by other trees far better than any other Pine tree, and even seems to enjoy being closely surrounded, a quality that makes it valuable for filling up in young forests where the native trees, on account of their slow growth, could not be brought up at all.

The White Pine is not so easily broken by heavy snow-fall as the Scotch Pine, on account of the greater elasticity of its wood. The great abundance of soft needles falling from it every year better fits it for improving a worn-out soil than any European Pine, therefore the tree has been tried with success as a nurse for the ground in forest plantations of Oak, when the latter begin to be thinned out by nature, and grass is growing underneath them.

And finally, all observations agree that the White Pine is a faster growing tree than any native Conifer in Europe, except, perhaps, the Larch. The exact facts about that point, taken from investigations on good soil in various parts of Germany, are as follows:

Years.	Height.	Annual Growth During Last Decade.
The White Pine at 20 reaches	7.5 meters.	37 centimeters
" 30 "	12.5 "	50 "
" 40 "	18.5 "	60 "
" 50 "	22.5 "	40 "
" 60 "	26.5 "	40 "
" 70 "	28.5 "	20 "
" 80 "	30.0 "	15 "
" 90 "	32.0 "	20 "

For comparison I add here the average growth on good soil, of the Scotch Pine, one of the most valuable and widely distributed timber trees of Europe.

Years.	Height.	Annual Growth During Last Decade.
The Scotch Pine at 20 reaches	7.3 meters.	36.5 centimeters
" 30 "	11.6 "	43.0 "
" 40 "	15.7 "	41.0 "
" 50 "	19.4 "	37.0 "
" 60 "	22.1 "	27.0 "
" 70 "	24.0 "	22.0 "
" 80 "	26.0 "	17.0 "
" 90 "	27.5 "	15.0 "
" 100 "	28.5 "	10.0 "
" 120 "	30.0 "	7.5 "

That is, the White Pine is ahead of its relative during its entire life and attains at 80 years a height which the Scotch Pine only reaches in 120 years. It appears then

that the whole volume of wood formed within a certain period by an acre of White Pine forest is greater than that yielded by a forest of Scotch Pine within the same period.

As far as reliable researches show, a forest of White Pine when seventy years old gives an annual increment of 3 cords of wood per acre. On the same area a forest of Scotch Pine increases every year by 2.4 cords on the best soil, 2 cords on medium soil, and 1.5 cords on poor soil.

But notwithstanding the splendid qualities which distinguish the White Pine as a forest tree its wood has never been looked upon with favor in Europe. Many of those who are cultivating the White Pine for business seem to expect that they will raise a heavy and durable wood. These are the qualities prized in their own timber trees, and they seem to think that the White Pine must be so highly prized at home for the same qualities, when in fact it is the lightness and softness of the wood which are considered in America. It would seem also that some European planters believe that a Pine tree exists which will yield more and at the same time heavier wood than any other tree on the same area. It is a general rule that the amount of woody substance annually formed on the same soil does not vary in any great degree with the different kinds of trees. For instance, if we have good soil we may raise 2,200 lbs. per acre of woody substance every year, from almost any kind of timber tree. If we plant a tree forming a wood of low specific gravity, we get a large volume of wood, and this is the case with the White Pine. If we plant on the same ground an Oak tree, we will get small volume of wood, but the weight of the woody substance will be the same, that is, 2,200 pounds of absolutely dried wood per acre.

It is remarkable that there is hardly any difference in the specific gravity of the wood of the White Pine grown in Europe and in its native country. I collected in Central Wisconsin wood-sections of a tall tree and compared the specific gravity with the wood of a full-grown tree of White Pine from a Bavarian forest. The average specific gravity of the Bavarian tree was 38.3. The average specific gravity of the American tree was 38.9. In both trees the specific gravity slightly increased from the base to the top. Professor Sargent gives 38 as the result of his numerous and careful investigations.

I was much surprised that the thickness of the sap-wood varied much in favor of the Bavarian tree.

	Of the Bavarian tree.	Of the American tree.
At the base	2.7 centimeters	9 centimeters.
In the middle	.4 "	6 "
Within the crown	.3 "	4 "

I am inclined to believe that on account of the generally drier climate of America a greater amount of water, and, therefore, of water-conducting sap-wood, is necessary to keep the balance between the evaporation and transportation of the water. The wood of the White Pine is certainly better fitted for many purposes than any tree with which nature has provided Europe, and yet one can hardly expect it to easily overcome fixed habits and prejudices. It will devolve upon the more intelligent proprietors of wood-land in Europe to begin with the plantation of the White Pine on a large scale. No Conifer in Europe can be cultivated with so little care and risk as the White Pine; the frost does not injure the young plant, and the numerous insects invading the European trees during their whole life-time inflict but little harm. Subterranean parasites are thinning out the plantations to some extent, but in no dangerous way.

H. Mayr.
Tokio, Japan.

Abies amabilis.--Professor John Macoun detected this species during the past summer upon many of the mountains of Vancouver's Island where with *Tsuga Pattoniana* it is common above 3,000 feet over the sea level. The northern distribution of this species as well as some other British Columbia trees is still a matter of conjecture. It has not been noticed north of the Fraser River, but it is not improbable that *Abies amabilis* will be found to extend far to the north along some of the mountain ranges of the north-west coast.

European Larch in Massachusetts.

IN 1876 the Trustees of the Massachusetts Society for the Promotion of Agriculture offered a premium for the best plantations of not less than five acres of European Larch. The conditions of the competition were that not less than 2,700 trees should be planted to the acre, and that only poor, worn-out land, or that unfit for agricultural purposes, be used in these plantations.

The prize was to be awarded at the end of ten years. The committee appointed to award the prize were C. S. Sargent and John Lowell. The ten years having expired, this Committee lately made the following report :

Mr. James Lawrence, of Groton, and Mr. J. D. W. French, of North Andover, made plantations during the spring of 1877 in competition for this prize. Mr. Lawrence, however, at the end of one year withdrew from the contest, and Mr. French is the only competitor. Your Committee have visited his plantation at different times during the past ten years, and have now made their final inspection. The plantation occupies a steep slope facing the south and covered with a thin coating of gravelly loam largely mixed towards the bottom of the hill with light sand. This field in 1877 was a fair sample of much of the hillside pasture land of the eastern part of the State. It had been early cleared, no doubt, of trees, and the light surface soil practically exhausted by cultivation. It was then used as a pasture, producing nothing but the scantiest growth of native Grasses and Sedges with a few stunted Pitch Pines. Land of this character has no value for tillage, and has practically little value for pasturage. Upon five acres of this land Mr. French planted fifteen thousand European Larch. The trees were one foot high, and were set in the sod four feet apart each way, except along the boundary of the field, where the plantation was made somewhat thicker. The cost of the plantation, as furnished by Mr. French, has been as follows :

15,000 Larch (imported),	\$108 50
Fencing,	20 81
Surveying,	6 00
Labor,	104 69
Total,	\$240 00

This, with compound interest at five per cent. for ten years, makes the entire cost to date of the plantation of five acres, \$390.90.

The Trees for several years grew slowly and not very satisfactorily. Several lost their leaders, and in various parts of the plantation small blocks failed entirely. The trees, however, have greatly improved during the last four years, and the entire surface of the ground is now, with one or two insignificant exceptions, sufficiently covered. There appear to be from 10,000 to 12,000 larch trees now growing on the five acres. The largest tree measured is 25 feet high, with a trunk 26 inches in circumference at the ground. There are several specimens of this size at least, and it is believed that all the trees, including many which have not yet commenced to grow rapidly or which have been overcrowded and stunted by their more vigorous neighbors, will average 12 feet in height, with trunks 10 to 12 inches in circumference at the ground. Many individuals have increased over four feet in height during the present year. It is interesting to note as an indication of what Massachusetts soil of poor quality is capable of producing, that various native trees have appeared spontaneously in the plantation since animals were excluded from this field. Among these are White Pines 6 to 8 feet high, Pitch Pines 14 feet high, a White Oak 15 feet high and a Gray Birch 17 feet high. The Trustees offered this prize in the belief that it would cause a plantation to be made capable of demonstrating that unproductive lands in this State could be cheaply covered with trees, and the result of Mr. French's experiment seems to be conclusive in this respect. It has shown that the European Larch can be grown rapidly and cheaply in this climate upon very poor soil, but it seems to us to have failed to show that this tree has advantages for general economic planting in this State which are not possessed in an equal degree by some of our native trees. Land which will produce a crop of Larch will produce in the same time at least a crop of white pine. There can be no comparison in the value of these two trees in Massachusetts. The White Pine is more easily transplanted than the Larch, it grows with equal and perhaps greater rapidity, and it produces material for which there is an assured and increasing demand. The White Pine, moreover, has so far escaped serious attacks of insects and dangerous fungoid diseases which now threaten to

exterminate in different parts of Europe extensive plantations of Larch.

Your Committee find that Mr. French has complied with all the requirements of the competition ; they recommend that the premium of one thousand dollars be paid to him.

Answers to Correspondents.

When the woods are cut clean in Southern New Hampshire White Pine comes in very, very thickly. Is it best to thin out the growth or allow the trees to crowd and shade the feebler ones slowly to death?
J. D. L.

It is better to thin such over-crowded seedlings early, if serviceable timber is wanted in the shortest time. The statement that close growth is needed to produce long, clean timber, needs some limitation. No plant can develop satisfactorily without sufficient light, air and feeding room. When trees are too thickly crowded the vigor of every one is impaired, and the process of establishing supremacy of individuals is prolonged, to the detriment even of those which are ultimately victorious. The length is drawn out disproportionately to the diameter, and all the trees remain weak.

Experience has proved that plantations where space is given for proper growth in their earlier years, yield more and better wood than do Nature's dense sowings. Two records are added in confirmation of this statement, and many others could be given :

1. A pine plantation of twelve acres was made, one half by sowing, the other half by planting at proper distances. In twenty-four years the first section had yielded, including the material obtained in thinnings, 1,998 cubic feet, and the latter, 3,495 cubic feet of wood. The thinnings had been made, when appearing necessary, at ten, fifteen and eighteen years in the planted section, yielding altogether ten and three-quarter cords of round firewood and seven cords of brush ; and at eight, ten and twenty years in the sowed section, with a yield of only three and one-fifth cords of round firewood at the last thinning and seven and four-fifths cords of brush wood.

2. A spruce growth seeded after thirty-three years was still so dense as to be impenetrable, with scarcely any increase, and the trees were covered with lichens. It was then thinned out when thirty-five, and again when forty-two years old. The appearance greatly improved, and the accretion in seven years after thinning showed 160 per cent. increase, or more than 26 per cent. every year.

The density of growth which will give the best results in all directions depends upon the kind of timber and soil conditions.
—B. E. Fernow.

Washington, D. C.

Book Reviews.

Gray's Elements of Botany.

FIFTY-ONE years ago, Asa Gray, then only twenty-six years of age, published a treatise on botany adapted to the use of schools and colleges. It was entitled "The Elements of Botany." Its method of arrangement was so admirably adapted to its purpose, and the treatment of all the subjects so mature and thorough, that the work served as a model for a large work which soon followed,—the well-known Botanical Text-book, and the same general plan has been followed in all the editions of the latter treatise. About twenty-five years after the appearance of the Elements, Dr. Gray prepared a more elementary work for the use of schools, since the Text-book had become rather too advanced and exhaustive for convenient use. This work was the "Lessons in Botany," a book which has been a great aid throughout the country, in introducing students to a knowledge of the principles of the science. Without referring to other educational works prepared by Dr. Gray, such as "How Plants Grow," etc., it suffices now to say that for two or three years, he had been convinced that there was need of a hand-book, different in essential particulars from any of its predecessors. When we remember that all of these had been very successful from an educational point of view, as well as from the more exacting one of the publishers, we can understand how strong must have been the motive which impelled the venerable but still active botanist to give a portion of his fast-flying time to the preparation of another elementary work. In answer to remonstrances from those who believed that the remnant of his days should be wholly given to the completion of the "Synoptical Flora," he was wont to say pleasantly, "Oh, I give only my evenings to the 'Elements.'" And, so, after a day's work, in which he had utilized every available moment of sunlight, he

would turn with the fresh alertness which has ever characterized every motion and every thought, to the preparation of what he called fondly, his "legacy" to young botanists. That precious legacy we have now before us.

In form it is much like the Lessons, but more compact and yet much more comprehensive. Its conciseness of expression is a study in itself. To give it the highest praise, it may be said to be French in its clearness and terseness. Not a word is wasted: hence, the author has been able to touch lightly and still with firmness every important line in this sketch of the principles of botany. This work, in the words of its author, "is intended to ground beginners in Structural Botany and the principles of vegetable life, mainly as concerns Flowering or Phanerogamous plants, with which botanical instruction should always begin; also to be a companion and interpreter to the Manuals and Floras by which the student threads his flowery way to a clear knowledge of the surrounding vegetable creation. Such a book, like a grammar, must needs abound in technical words, which thus arrayed may seem formidable; nevertheless, if rightly apprehended, this treatise should teach that the study of botany is not the learning of names and terms, but the acquisition of knowledge and ideas. No effort should be made to commit technical terms to memory. Any term used in describing a plant or explaining its structure can be looked up when it is wanted, and that should suffice. On the other hand, plans of structure, types, adaptations, and modifications, once understood, are not readily forgotten; and they give meaning and interest to the technical terms used in explaining them."

The specific directions given for collecting plants, for preparing herbarium specimens, and for investigating the structure of plants make this treatise of great use to those who are obliged to study without a teacher. The very extensive glossary makes the work of value not only to this class of students, but to those, as well, whose pursuits are directed in our schools. The work fills, in short, the very place which Dr. Gray designed it should.

G. L. Goodale.

The Kansas Forest Trees Identified by Leaves and Fruit, by W. A. Kellerman, Ph.D., and Mrs. W. A. Kellerman (Manhattan, Kansas). This octavo pamphlet of only a dozen pages contains a convenient artificial key for the rapid determination of seventy-five species of trees. By the use of obvious characters the authors have made the work of identification comparatively easy in nearly every instance, and even in the few doubtful cases, the student will not be allowed to go far astray. The little hand-book ought to be found of use even beyond the limits of the State for which it was designed.

G. L. Goodale.

Public Works.

The Falls of Minnehaha.—A tract of fifty acres, beautifully located on the Mississippi, opposite the mouth of the Minnehaha, has been acquired by the City of St. Paul, and land will most probably be secured for a drive of several miles along the river. The bank here is more than 100 feet high, often precipitous, clothed with a rich growth of primeval forest, shrubby and vines. It is hoped that Minneapolis may secure the land immediately opposite, including the Falls of Minnehaha and the valley of the stream to the great river. In this event a great park could be made between the two cities, easily reached from the best part of both, with the Mississippi flowing through it and the Falls as one of its features. This, in connection with the park so beautifully situated on Lake Como, three miles from St. Paul, and the neat parks of Minneapolis and its superbly kept system of lake shore drives, would soon be an object worthy of the civic pride of these enterprising and friendly rivals.

A Park for Wilmington, Del.—After many delays and defeats the people of this city have secured a tract of more than 100 acres, mostly of fine rocky woodland, with the classic Brandywine flowing through it, and all within the city limits, together with two smaller tracts, one a high wooded slope, the other lying on tide water, and both convenient to those parts of the city inhabited by workmen and their families. A topographical survey of these park lands is now in progress as preparation for a general plan of improvement. Of the "Brandywine Glen" Mr. Frederick Law Olmsted once wrote: "It is a passage of natural scenery which, to a larger city, would be of rare value—so rare and desirable that in a number of cities several million dollars have been willingly spent to obtain results of which the best that can be said is, that they somewhat distantly approach, in character and expression, such scenery as the people of Wilmington have provided for them without expense."

Flower Market.

Retail Prices in the Flower Market.

NEW YORK, February 23d.

There is a glut of flowers, particularly of tea roses of an indifferent quality. Bon Silene buds cost from 75 cts. to \$1 a dozen, Perle des Jardins, Niphetos, Souvenir d'un Ami, and Papa Gontiers bring \$1.50 a dozen. C. Mermets are very fine and from 30 to 35 cts. each. Not more than one in three La France roses is perfect; they bring from 25 cts. to 50 cts. each. Mde. Cuisin and Duke of Connaught are 25 cts. each, Bennets 20 cts. each and Brides 25 cts. each. American Beauties are \$1 to \$1.50 each, according to the location where they are sold. Puritans cost 75 cts. each, and Jacqueminots 50 cts. Magna Chartas are the most popular of the hybrid roses at present. They, Anna de Diesbach and Mad. Gabriel Luizet bring from \$1 to \$1.50 each.

Mignonette is very plentiful, well grown and of the spiral variety; it brings 75 cts. a dozen spikes retail, very large spikes bring as high as 15 cts. each. Hyacinths, Lilies-of-the-Valley and Tulips bring \$1 a dozen. Lilacs cost 25 cts. for a spray of one or two tassels. Violets are abundant, mostly of the Marie Louise variety, and bring \$2 a hundred. Fancy long stem red Carnations cost 75 cts. a dozen; short stem Carnations are 50 cts. a dozen; and the dyed Carnations, named "Emerald," are in brisk demand and sell for 15 cts. each. Daffodils are \$1 a dozen; those dyed bring 20 cts. each. Finely grown Forget-me-not brought in small quantity to retail dealers sells for 10 cts. a spray. Calla Lilies bring \$2 and \$3 a dozen, and Longiflorum Lilies \$4 a dozen.

PHILADELPHIA, February 23d.

Heavy demands for flowers dropped off short on Ash Wednesday, and decreased each day until Saturday, when the regular orders for loose flowers caused the trade to pick up again. The demand for Orchids is steadily growing; a fair quantity is used at balls and parties, but nothing in comparison to Roses, Violets and Lily-of-the-Valley. Violets have been in greater demand, so far, than for several years. Large quantities of Tulips have been used recently for table decorations, especially the pink varieties, the favorite color for dinners and lunches. The American Beauty Rose, when cut with long stems, and really first class in every other respect, has been in great demand, at the best prices. Md. Gabrielle Luizet is scarce, the local growers not having commenced to cut in quantity; it is frequently asked for. Carnation plateaus in solid colors have been used freely. Lilacs are considered choice and have been in good demand. Retail prices rule as follows: Orchids, from 25 cts. to \$1 each; La France, Mermet, Bride and Bennet Roses, \$3 per dozen; Jacques, \$4 to \$5; American Beauty, \$4 to \$9; Puritan, \$4; Anna de Diesbach, \$5 to \$7.50; Papa Gontier, Sunset, Perle des Jardins and Mad. Cuisin, \$1.50; Bon Silene, \$1.00; Niphetos, \$1 to \$1.50. Lily-of-the-Valley, and Roman Hyacinths, bring \$1 per dozen; Mignonette, 50 cts., and Freesia the same per dozen; Heliotrope, Pansies, Carnations, and Forget-me-nots, 35 cts. per dozen. Violets bring from \$1 to \$1.50 per hundred; Lilium Harrisii, \$3.00 per dozen; Callas \$2 per dozen, and Lilacs \$2 per bunch of about eight sprays. Daffodils sell briskly at from \$1 to \$1.50 per dozen.

BOSTON, February 23d.

The season of Lent is always looked forward to by the florists with anxiety, for the rest from receptions, assemblies and balls cuts off one of the chief outlets for the choicest flowers: a few warm days are sufficient to overstock the market, and prices take a fall. Buyers are learning, however, that at no period of the year can cut flowers be had in such perfection and variety as during February and March, and although not much required for party occasions they are bought for other purposes in increasing quantities every year, so that the advent of Lent does not now produce utter stagnation in the flower trade. In Roses there is at present a large assortment offered. From the modest Bon Silene, and its new competitor, Papa Gontier, up to the magnificent American Beauty and Hybrid Perpetuals, may be found every gradation of color, size and fragrance. Retail prices vary from 75 cts. per dozen for Bon Silenes and \$1.50 to \$2 for Perles, Niphetos, etc., up to \$3 and \$4 for the best Mermets, Niels and La France; Hybrids and Jacques of best quality bring from \$6 to \$9 per dozen. In bulbous flowers a large variety is shown. Lily-of-the-Valley sells for \$1.50 per dozen sprays; Narcissus of various kinds, Hyacinths and Tulips for \$1 per dozen; Violets, 50 cts. per bunch; Pansies, Mignonette, Heliotrope, Forget-me-not and Calendulas, 50 cts. per doz. Long stemmed Carnations are to be had in great variety at 75 cts. per dozen; Callas 25 cts. each, and Smilax 50 cts. a string. At this season Smilax is at its best, being its time of flowering, and the flowers are deliciously fragrant.

Publishers' Note.

A photogravure of Mr. A. St. Gaudens's bronze medallion of the late Professor Asa Gray will be published as a supplement to the second number of GARDEN AND FOREST.

The Future of American Gardening.

IT is not surprising that few examples of the gardener's art in its highest development should be met with in America, especially in the more recently settled portions of the country. Even where the designing and planting of a garden are good, the element of time is needed to produce that ripeness and repose which are so satisfying to the contemplative mind. This mellow maturity which yet gives no hint of deterioration and decay only comes with years of care. A new country, or one of shifting population not only lacks the interest which accompanies long continued human association, but nature itself is not subdued into that tranquil and home-like aspect which is worn only where generation has succeeded generation, each impelled by a strong local attachment to its birth-place to conserve and develop its native beauties with affection and intelligence.

And yet the American people are inferior to none in general and genuine appreciation of natural beauty, and no country in the world is endowed with nobler landscape features, a more hospitable climate, or a greater richness and variety of vegetation than our own. Nowhere are flowers more universally cultivated or grown with greater skill. In no other country has the business of the florist been so developed and improved. Nowhere else have the various forms of so-called "decorative gardening" been so profusely practiced. Much of this might perhaps fall under the condemnation of severe taste, but some excuse for it is found in the fact that we have been constantly struggling against wild nature, and something trim and prim, ornate and artificial, is demanded, as a sign that nature has been subjugated. It is noteworthy that those who have been brought up on the pioneer line of civilization, admire, when they come to the older States, a formal flower bed more than they do the best examples of planting in the natural style, and this is perhaps because the latter is more suggestive of the untamed forces with which

they always have been forced to fight. But whatever may be the cause of this devotion to formal flower gardening, the fact remains that the plants themselves are cultivated with singular knowledge and success.

On the other hand, in love of trees and skill in their cultivation, we are far behind the English and Italians. In street planting, especially in our larger towns, we have much to learn from the French, the Germans and other continental nations, while in the skillful use of hardy shrubs and herbaceous plants we are far excelled by other nations. Great progress, however, has been made in this country of late years in the cultivation of orchids and various classes of green-house plants, and of these America now possesses collections hardly surpassed anywhere. And finally, in the highest branch of gardening, the creation of landscape pictures, for which the growing of trees and shrubs and flowers and vines is but mixing the colors on the palette, we have still much to learn from older countries. And yet, that American ability for work of this kind is not excelled, is shown by some of the fine old places on the Hudson, planted early in the century, largely with native trees, which would kindle admiration anywhere. Our older parks, too, like those of New York and Brooklyn, are consistent and impressive works of art, and in spite of much neglect and mismanagement, are noble monuments of their designers' taste and skill.

And there are signs of awakening here in artistic gardening. This is seen in the many instances where men of wealth are preparing spacious pleasure grounds about their houses, and in the growing desire among those of more modest means to beautify their home surroundings. Above all is this tendency manifested in the more frequent inquiry for aid from landscape gardeners and in the number of young men who are turning toward this profession as one which has in it the hope of emolument and distinction.

The future of gardening in America, then, is bright with promise. Our country offers to the landscape gardener wonderful advantages in its endless variety of scenery, the unrivaled richness of its Flora, and such diversity of soil and climate that somewhere within its borders every extra-tropical plant will grow. The imagination can conceive of nothing more lovely and refreshing than a spring garden in New England when vegetation bursts suddenly forth from the restraints of the long winter; nothing more glorious than the color that flames through New England woodlands when trees and shrubs and humbler plants are preparing for their season of rest. And what a field for the artist is offered in the warm rich valleys of the southern Alleghenies, the home of the most beautiful deciduous forest of the world! And as trees and shrubs which have developed under the same sky, blend in softer and more perfect harmonies of form and color than do those brought together from different climates and continents, here where the American forest culminates in its greatest beauty and richness of composition, the artist capable of using all this wealth of vegetation will find his greatest opportunity. And here, too, he can collect, if Nature has not supplied him with sufficient material for his pictures, the plants of all the temperate zones—the evergreens of China and Japan, the Rhododendrons of the Himalayas, the trees of Europe and the Conifers from the highlands of Mexico. Another ideal garden could be made on our north-west coast, where plants which luxuriate in the moist regions of the temperate zone would be at home; while in southern California could be gathered the trees of the Mexican plateau, of the Mediterranean basin, of Australia, and of all the dry countries of the world, and here gardens might be made surpassing in richness and variety of interest even those of the Riviera.

With such advantages we may reasonably look forward to a time when this country will be a land of gardens. What is now needed is that the gathering interest in planting should be properly directed and developed. The basis of

good gardening is the love of nature. To nature the gardener who would be something more than a mere cultivator of plants must turn for inspiration. From the study of nature alone can be learned composition, harmony and fitness in arrangement, and without these the gardener can never hope for success in the creation of a landscape.

To the notes on some American Thorns in another column; it may be well to add that Michigan Thorns give but a faint idea of the value of the different American species of this genus as ornamental plants. The real home of the American Thorn is in the region south of the Red River—that is, in western Louisiana and eastern Texas. Here can be found growing a larger number of species of this genus than in any other part of the world; and here many of our species reach their greatest individual development. Here only can be found the blue fruited *C. brachyacantha*, bordering the low, wet prairies of western Louisiana—one of the largest of the genus, and beautiful in habit, foliage, flowers and fruit. Here, too, the white-barked *C. arborescens*, the largest of the genus, the graceful and delicate *C. apiifolia* and *C. æstivalis*, all reach a development unknown in other parts of the country. The last is one of the most ornamental of the American Thorns. Its large flowers appear in February, and these are succeeded three months later by large, very fragrant, scarlet fruit, which is gathered and sold in great quantities in some of the markets of the South, where it is used for making a conserve. This species probably produces the most valuable fruit of any of the genus; although it must not be forgotten that one of the Thorns of the South Atlantic States (*C. flava*, var. *pubescens*) yields a fruit highly esteemed in the preparation of jellies, which when well made can hardly be distinguished from the true Guavajelly. In the Eastern States, *C. Crus-galli*, all things considered, is the most valuable of our Thorns as an ornamental tree. Its habit, profuse bloom, bright, shining foliage, brilliant autumnal coloring and large, red fruit, untouched by any animal, and hanging upon the trees until February, make this one of the most desirable of all small ornamental trees for American lawns. This, too, is one of the few American trees which seems to thrive in all European climates. A beautiful species of the very largest size, too, is *C. Douglasii* of our north-west coast and northern California, with foliage resembling that of *C. Crus-galli*, but with black fruit, ripening in August. This tree flourishes at the East, flowering and ripening its fruit freely in Massachusetts. We shall have occasion to return to the American Thorns in future numbers.

“To gild refined gold and paint the Lily, to throw a perfume on the Violet”—these are ancient synonyms for lack of judgment and lack of taste, for “wasteful and ridiculous excess.” Yet even their century-long citation has not protected us from a sight of the actual follies they hold up to scorn. So far as we know, an effort has not recently been made to improve the Violet's odor, but we almost expect to hear of such an effort, for the Lily is being painted with much ingenuity and perseverance. Carnations with bright green borders, Daffodils likewise edged with green, Lilies-of-the-Valley dyed a pale red and Callas tipped with pink—these are some of the “novelties” which greet us in many florists' windows. If they were shown merely as curiosities, merely as examples of what can be done in defiance of nature's intentions, the case would be bad enough. But as our readers may have seen in the flower-market report in our last issue, dyed Carnations are in “brisk” commercial demand at fifteen cents each and dyed Daffodils at twenty cents!

We have no wish to fall back upon theoretic preachments in protesting against the lack of taste which this fact implies. There is no reason why we should not attempt to modify the original color of flowers, and this is constantly done by skillful hybridizing, cross-breeding and

culture. But in such cases we work in accord with natural laws, and the result may be beautiful, and certainly it is not monstrous. But a single glance at a dyed blossom will suffice to prove the artistic brutality of the new process. The “Emerald” is the trade name for the dyed Carnation, it might better have been the “Arsenic”; the combination of the same arsenical tint with the yellow of the Daffodil is excruciating to the eye; the pink-edged Calla is almost loathsome in effect; and all explain themselves at once as having undergone artificial manipulation. We believe the process by which some of them are produced is analogous to that by means of which the human skin may be tattooed, and the result appeals to the same grade of taste. We might as soon have expected to see a lady with a blue anchor on her wrist as with an “Emerald” Carnation in her buttonhole.

Landscape Gardening.—II.

TO produce beautiful compositions is the aim of every artist, and the special aim of the landscape gardener is to produce them by arranging the surface of the ground and the plants it bears. It is interesting and instructive to note the points of concord and of contrast which mark his task when it is compared with that of other artists.

He stands with the sculptor and the painter, in contrast to the architect and musician, in that he takes his inspirations directly from nature—works after the schemes and from the models which she supplies. But in some respects he stands quite alone. The painter works with actual colors but merely with illusions of form. The sculptor creates forms but uses colors, if at all, in unnaturalistic and subordinate ways. The landscape gardener depends upon color and form in equal measure and can never dispense with the one or the other.

Moreover, he takes from nature not only his models but his materials and his methods. His colors are those of her own palette, his clays and marbles are her rocks and soils, and his technical processes are the same which she employs. He does not show her possibilities of beauty as in a mirror of his own inventing. He helps her in her actual efforts to realize them—works in and for and with her.

This fact limits and hampers him in certain ways; but under fortunate conditions it helps him to achieve what no other artist can—perfection. “The sculptor or the painter,” writes a recent critic, “observes defects in the single model; he notices in many models scattered excellences. . . . To correct those defects, to reunite those excellences, becomes his aim. He cannot rival nature by producing anything exactly like her work but he can create something which shall show what nature strives after. . . . The mind of man comprehends her effort and though the skill of man cannot compete with her in the production of particulars, man is able by art to anticipate her desires and to exhibit an image of what she was intending.” But the landscape gardener is nature's rival, does create things exactly like her own, can compete with her in perfect workmanship—for does not she herself work with him while he is reuniting her scattered excellences of idea and obliterating her defects? What he cannot do she does for him, from the building of mountains and the spreading of seas to the perfecting of those “particulars” which turn the keenest chisel and blunt the subtlest brush—to the curling of a fern-frond and the veining of a rose. Of course she will not everywhere do everything. If part of her work is in completing man's, part is in preparing for it, and he must respect the frame which she furnishes for his picture, the general scheme which she prescribes. He cannot ask her to build him mountains in a plain, to change a hill-side rivulet to a river, or to make tropical trees grow under a northern sky. But he can always persuade her to produce beauty of some sort if he is wise enough to know for what sort he should ask.

This, of course, is theoretic speaking. Theoretically,

there is no spot on earth an artist could not make beautiful. But some problems would need a life of antediluvian length and dollars as plentiful as the sands of the sea. Practically the landscape gardener—like all other men, and more perhaps than most other artists—is limited by questions of time and money. And he is also limited by his partnership with nature as regards not only the sort but the degree of beauty to which he can attain. Nature may suggest the same sort in two places, but if she prepares lavishly for it in the one case and parsimoniously in the other, the best skill in the world may not be able to make good all her denials and equalize its successes. Yet the landscape gardener can always have what no other artist ever gets—perfection in details; and his general effects, as well as his details, have the great advantage of being concrete and alive. A great advantage indeed—for it means many beautiful results in every piece of work instead of merely one, and perpetual variation in each of the many. His aim is in general the same as that of the landscape painter, who knows that the most potent factors in landscape beauty are light and atmosphere, and who is himself most potent as he simulates them best. But no things in the world—not even the color and texture of the human skin—are so difficult to simulate, so impossible really to reproduce in paint. To the landscape gardener's pictures nature freely supplies them, everywhere and always, and not merely in the one phase for which the painter strives, but in a thousand—changing them with each day of the year and with each hour of the day. And with the passing days and seasons she changes also his terrestrial effects, so that no part of his work is ever twice the same although, if rightly wrought, it is always beautiful. Thus it gives chance and promise for perpetual renewal of the highest kind of pleasure. Our judgments are persistent but our moods continually vary, and we may expect more days of perfect satisfaction from the variable than from the changeless work of art. If we admire a picture we admire it always, but while it may suit us to-day to the inmost fibre of the soul, to-morrow it may leave us cold. Of course there are drawbacks as well as benefits in variability—possibilities of perfect satisfaction are richer in the living landscape, but when realized we cannot keep them for an hour while we are sure of our painting within its narrow range. It will depend upon our temperament which excellence we prefer: limited certainty or uncertain infinitude. But the question does not involve beauty itself—it only involves that finest effect of beauty which means perfect momentary accord between the spirit of the observer and the spirit of the work of art. As regards intrinsic perfection, the best results of the landscape gardener surpass the best painted landscapes by as wide an interval and for the same great reasons as Pygmalion's Galatea surpassed all the other statues which he may have made.

M. G. Van Rensselaer.

Professor Anton de Bary.

HEINRICH Anton de Bary, who was born at Frankfort-on-the-Main, Jan. 26th, 1831, and died at Strasburg, Jan. 19th, 1888, was a striking example of a scientific man who, while pursuing science for its own sake, proved also a benefactor to those engaged in the practical work of horticulture and agriculture in consequence of his brilliant discoveries in vegetable pathology. His botanical career began immediately after he left the university where he had devoted himself to the study of medicine, and, although at the time of his death he had not passed the period of middle age, few have exerted so marked an influence in shaping the course of the botany of the present day. For a short time he was the assistant of Professor Hugo von Mohl at Tubingen and an instructor in botany. In 1855 he was called to Freiburg in Brisgau as Assistant Professor of Botany and Director of the Botanical Garden, where he remained until 1867, when he accepted a professorship at Halle. Shortly after the close of the Franco-German war, in 1872, he was appointed professor in the reorganized University of Strasburg, a

position which he held until his death, although he had tempting calls to Vienna, Berlin and Leipsic. In the summer of 1887 he was attacked by what proved afterwards to be a tumor of the jaw, and, although he submitted to an operation in the hope of relief, he succumbed to the disease after several months of suffering.

The botanical works of Professor De Bary relate principally to the structure and development of cryptogams, but he was also the author of a number of papers on histological subjects, and his "Comparative Anatomy of the Vegetative Organs of Phanerogams and Ferns," published in 1877 and since translated into English, is the best general work on the subject in existence. At one time he was interested in the study of algae and published important papers on *Conjugateæ*, on *Oedogonium* and *Bolbochateæ*, and on the marine species, *Acetabularia Mediterranea*. We should also mention his important work on Apogamy in Ferns, in which he gave a detailed account of the manner in which the sexual reproduction in ferns may be replaced by a non-sexual growth, with remarks on apogamy in other groups.

But his most important work and that which is of most interest to our readers was on the development of Fungi, especially those which produce disease in plants. One of his earliest publications, in 1853, was "Investigations on the Rust-fungi," especially those which cause diseases of grain and other useful plants. This work was a careful study of a number of species then supposed to belong to *Uredineæ*, rusts, and *Ustilagineæ*, smuts. At that date De Bary adhered to the views of older writers, and considered that the rust stage, or *Uredo*, was not connected with the final, or teleutospore forms, like *Puccinia*. It was not until the publication of Tulasne's paper in 1854 that botanists recognized that the red rust, the *Uredo*, was only a stage of the black rust. In a remarkable paper published in 1863, "Researches on the Development of some Parasitic Fungi," De Bary showed by an examination of *Uromyces appendiculatus*, the Bean-rust, that not only were there two stages, the *Uredo* or red rust, and the teleutospore, or black rust, but that a third stage, the *Æcidium*, or cluster-cup, is found in Fungi of the rust family. In 1865 in his "New Observations on *Uredineæ*" and in a supplement published the following year he gave an account of his experiments in which he showed that the cluster-cup growing on the Barberry is a stage of the *Puccinia*, or blight, found on different grains and grasses. These conclusions, warmly supported by some and opposed by others, may be considered the starting point of one of the most fascinating, and, from a practical point of view, most important fields of botanical study, the metamorphoses of *Uredineæ*. Scarcely less important than the paper last mentioned is that on *Æcidium Abietinum*, in 1879, where a very minute account is given of the different stages of the rust on *Abies excelsa* and *Rhododendron ferrugineum*.

The researches of De Bary on the Potato rot are well known. The Fungus which causes the rot was first described in 1845 by Madame Libert, a Belgian botanist. De Bary, in 1860, described the method of the germination of the conidial spores and the production of zoospores—an important discovery, practically as well as theoretically. In his "Researches," published in 1863, to which we have already referred, he included an account of the rots, *Peronospora*, which is a model of thoroughness and clearness. Besides these, he published in 1861 a paper on the "Present Epidemic Disease of Potatoes," a popular, well written sketch, and in 1876, "Researches into the Nature of the Potato Fungus," in which he embodied the results of investigations made at the request of the Royal Agricultural Society of Great Britain, in which there is not much added to our knowledge of the subject.

We can only refer briefly to De Bary's other mycological writings, which appeal rather to the specialist than the general reader. He contributed much to our knowledge of the *Myxomycetes*, a group whose position is still doubtful, some regarding them as animals and others as plants, and he published numerous valuable papers on *Saprolegnieæ*, *Ascomycetes*, and other orders of Fungi. We owe to him the best summary of what is at present known about Fungi. His "Comparative Morphology and Biology of Fungi, Mycetozoa and Bacteria," issued in 1884, and recently translated into English, is an admirable treatise on a subject which attracts more and more students every year. Nor should we forget his "Lectures on Bacteria," of which a second edition has been issued, although the first only appeared in 1885. These lectures present, in a most attractive and readable form, the present state of bacteriological science.

De Bary was an excellent teacher, as well as an original investigator. In the lecture room he was not seen to such advantage as when in his laboratory among a small number

of earnest students. His delivery was not marked by any rhetorical elegance, but his lectures were crammed with facts, and his remarks were always to the point and full of suggestions. His laboratory was a resort of special students from both sides of the Atlantic, and the list of younger professors who now point with pride to the fact that they were once his pupils, is a very large one. Earnestness and thoroughness characterized his work both as a teacher and an investigator, and his geniality and sprightliness made him a great favorite with all who knew him.

W. G. Farlow.

Winter in Mobile.

IN ordinary years the waves of low temperature from the north are felt to some extent through the coast regions of the Gulf States. Heralded by a northern blast which clears the sky, come a few clear frosty days, or occasionally a slight fall of evanescent snow; then plant life takes a brief rest, and the landscape, for a space, assumes a wintry look. Usually the departure of the last Rose of summer, which lingers till mid-December in our gardens, is followed by a rest in vegetation, which awakes again under the breath of spring in late January. This year, however, the mean daily temperature of December was 50° and we had but two slight frosts. The annual garden weeds, like *Enothera humifusa*, Chickweed, Peppergrass, and intruders like *Veronica peregrina* and *Lamium amplexicaule*, kept up luxurious growth all winter long, and the low Speargrass (*Poa annua*) covered waste places with its sward of lively green, without any interruption. Several of our late autumnal plants, like some species of *Chrysopsis* and *Aster*, under cover of the woods, were found blooming long after New Year's. The Japanese plum, *Eriobotrya Japonica*, began to bloom in early November, and continued to unfold its panicles of fragrant white flowers until the close of the year, mingling their perfume with that of the flowers of the Sweet Olive (*Olea fragrans*). Violets, Candytuft, Sweet Alyssum and Daisies bloomed abundantly, as did the Sweet Olive and all varieties of the Camellia. Among the forest trees, the White Cedar was in full bloom on the first day of December, and the leaves of deciduous trees were still vivid with their autumnal tints. Festoons of different species of *Smilax*, loaded with berry clusters of gleaming scarlet or purple black, were clambering over the broad leaved evergreens, giving to the midwinter woodlands a tropical beauty, in the presence of which it was hard to realize that our northern States were swept by blizzards. In fact, it seemed that autumn joined hands with spring, the year passing almost imperceptibly from one to the other.

The January weather was still more remarkable, showing the mean temperature to be only 54°. Before the end of its second week, *Viburnum protensum*, one of our hardiest exotic shrubs, taking the lead among the harbingers of spring, was followed promptly by an early Honeysuckle, with its fragrant pale rose flowers, while *Narcissus* and *Hyacinths* were adorning our flower beds. Later in the month the thermometer fell to 20°, and the mean temperature for five days was 46°. But the slight injury caused to vegetation quickly vanished with the sunny days that followed and plant life proceeded without a check until the present time.

In January, too, the Japan Quince blazed with scarlet bloom and the Forsythia hung out its golden bells, and in the last week of the month our southern Bluets, *Houstonia patens*, were smiling in the pastures and pine barrens. In the forests, the Cypress, the Red Cedar and the Swamp Maple were in full bloom, as was the *Alder* along the banks of the streams, while climbing over the bushes the loveliest of our wild vines, the Yellow Jessamine, had begun to unfold its flowers.

Mobile, February 15th.

Karl Mohr.

Foreign Correspondence.

London Letter.

Lælia albida, a lovely little Mexican Orchid, with its ivory white and fragrant flowers, is one of the best of all winter flowering Orchids, and especially valuable because it can always be relied on for Christmas bloom. A single spike is beautiful, but imagine a mass of it three feet across, carrying no fewer than 400 flowers! Such is the sight I enjoyed the other day in Sander's Orchid nursery. There were two masses of almost equal size growing on flat rafts, and suspended over a water tank, surrounded by great blocks of artificial rock, in a large intermediate Orchid-house. The two plants have together over 800 flowers, a charming mass of delicate white and pink, for the lips of all the flowers are rose-tinted. The fra-

grance, too, of such a quantity of bloom was delicious, and pervaded the whole house. Both masses were in the same state as when imported, and are supposed to be the largest ever brought to England alive. This *Lælia* is not only one of the prettiest of winter Orchids, but is one of the easiest to grow, merely requiring to be placed on wood blocks or in baskets, in what we call here a cool house, one in which the summer temperature ranges from 60° to 70°, and not falling below 45° on winter nights.

A new *Angræcum*, which proves to be one of the prettiest ever introduced, was lately exhibited here for the first time by the Messrs. Sander, under the name of *A. Sanderianum*, and won the highest certificate of merit. It is small in growth, having a few long, thick leaves of deep green, and about two inches wide. The flower spike is about a foot long of a soft fawn color and thickly beset with flowers. These are about an inch across, with snow-white sepals and petals, and slender white spurs some three inches in length. The flowers being so numerous, and of such purity, and the spikes so graceful, the effect of the flowering plants is charming. I saw the same plant in the St. Albans Orchid nursery by the hundred, every one being in bloom, with two and three spikes on each. It is therefore very floriferous, and is considered one of the easiest to manage. The thicket of white flower spikes, all gracefully drooping from suspended plants, was one of the most pleasing sights I have seen among Orchids.

Percival's Cattleya, one of the newer varieties of the polymorphous *C. labiata*, heralded the flower season of this genus. Those who confine their collection of Orchids to the most select must include this one, as it is not only the earliest flowering of all, but one of the most beautiful. When introduced a few years ago it was said to be autumn flowering, but it has not proved to be so here, although I am told that in America it flowers some weeks before it opens here. At Sander's nursery about holidays this *Cattleya* was the chief feature, hundreds of plants being in bloom, exhibiting a great variation of color, some being many shades darker than others. It is what one would call a medium-sized *Cattleya*. The sepals and petals are a deep rose pink, and the lip is invariably adorned with an intensely deep blotch of maroon crimson, which looks like velvet. It is a very free flowering kind, and with us is not at all difficult to grow well.

The *Snowy Masdevallia tovarensis* and the fiery-looking *M. ignea* are two invaluable winter Orchids, both being in bloom now. I have recently seen a plant of the white carrying sixty flowers in twos and threes on each spike, and another of *M. ignea* whose flowers are orange scarlet, lined with crimson, with forty flowers, evidence of how these gems of the South American Andes flourish in England. I suspect that American Orchid-growers have some difficulty in growing these cool mountain Orchids on account of your hot and dry summers, but in any place where they succeed the two I have named here should be grown in gardens as largely as their owner's accommodation and pocket can afford.

A beautiful green-house climber named *Oxera pulchella*, from New Caledonia, and entirely new to European gardens, was shown here recently for the first time by Sir George Macleay. The plant is nearly allied to *Clerodendron* and in habit of growth resembles the climbing species of that genus. It has long, slender branches, with deep green shining leaves, like those of *Stephanotis*. The flowers are large, tubular and wide-mouthed, pure white and with two protruding stamens. They are borne in large, dense clusters, a score or more together on the leaf axils. It is extremely floriferous, as a flower cluster is borne from almost every leaf point. It is looked upon as a most valuable addition to green-house plants, more particularly as it flowers habitually in the depth of winter, when most appreciated. It will become a popular climber, and the gardener who grew the specimen exhibited, assures me that it is easily cultivated. He grows it in an airy green-house trained to a rafter of the roof. It was brought from a garden in Algiers. The genus *Oxera* has been hitherto unknown to English gardens, and till recently botanists knew but one species, but now they number ten. This climber is, unquestionably, one of the most remarkable plants exhibited of late years.

Kennedy's Marryattæ (*K. prostrata*, var. *major*, D. C.), an Australian climbing plant of the Pea family, has been for some time the glory of one of the green-houses in Kew Gardens, and yet it is to be found in few private gardens, though it is such an old plant and so beautiful. I should be glad to hear that it was more generally appreciated in America. No other green-

house climber can compare with it in midwinter, and the fact that it requires little or no cultural attention, if once well planted in an ordinary green-house, enhances its value. At Kew it is planted out in free soil beneath the side stage; the main stem is trained up the rafter on one side of the span roofed house and down the one on the opposite side. The shoots, varying from two to six feet long, are thickly wreathed with bright scarlet flowers, like miniature lobster claws in shape, among the pale green trifoliate leaves, and the whole forms an exquisite floral curtain across the house. It should not be planted out until it gets a good size, as it wants all the light possible when small in order to get strong. When well rooted and about five or six feet high plant it out in a green-house that is well ventilated and has a minimum Winter temperature of about 40° F. I imagine that your hot summers would suit the plant well and so ripen the wood that its winter bloom would be abundant. Besides flowering for several weeks in succession in midwinter, it flowers in spring and summer; in fact, it might be almost called a perpetual bloomer.

The Crimean Lime (*Tilia petiolaris*) promises to become one of our most ornamental deciduous trees. Though not new

quite distinct from the Hungarian linden, as Sir Joseph Hooker pointed out several years ago (*Botanical Magazine*, t. 6737.) It is one of the most promising ornamental deciduous trees ever introduced into this country. Fine specimens may be seen in the Central Park in this city.—E.D.)

Rhododendron primrose is the finest yellow flowered variety that has yet been obtained among the Javanese or Green-house Rhododendrons which the Messrs. Veitch, of Chelsea, have for years been occupied in improving by hybridizing. This variety, Primrose, is the result of intercrossing a small, pale yellow flowered species named *R. teysmannia* with a hybrid variety with large well formed flowers of a yellowish pink tint, called Maiden's Blush, raised several years ago. The new hybrid had flowers over one and one-half inches across, with broad, overlapping petals, making a handsome symmetrical flower. The color is a clear yellow, with not a trace of the pink tinge of its male parent. It is considered a great stride in advance in the production of a yellow flowered race of green-house Rhododendrons. W. Goldring.

Entrance to the Arnold Arboretum.

here, in a nurseryman's sense, it is but little known and rarely planted, though the other silver-leaved Lime, the Hungarian lime (*T. argentea*), is a common stock plant. For many years the Crimean Lime has been known in English nurseries under the erroneous name of *T. Americana pendula*, but its true name is now being adopted. It is an extremely fine tree and different from the other Limes. Its leaves are large, heart shaped, of a deep green above and silvery white beneath. The slender twigs are pendulous, and as the leaf stalks are long and slender, the whole tree is of a gracefully weeping habit, of rounded outline and moderately dense. Perhaps the finest specimen in the country exists in Mr. Maurice Young's nursery at Milford in Surrey. This tree is about sixty feet in height, has a huge head fifty or sixty feet through, and has a diameter of stem of about two feet, and yet it exhibits all the elegance of growth of a young tree. It must be a fast growing Lime, as this large tree has certainly been planted since 1838, when Loudon compiled his Arboretum. At that time it was considered to be a variety only of *T. argentea* and though cultivated at Odessa, was not yet introduced into England.

(The Crimean lime is also generally known in the United States as *Tilia argentea pendula*, although specifically

Entrance to the Arnold Arboretum.

NO coniferous tree excels the Hemlock Spruce when young in grace of outline, softness of spray or brightness of color. As it grows older it becomes a tree of stately proportions, with drooping branches thickly furnished with dark leaves. When massed in northern woods or in the high mountains further south it invests the forest with the charm of a mystery peculiarly its own. North of the drift line, wherever a stream of water has furrowed out a deep gorge, the Hemlock often takes possession of the slopes, making dark glens that are always attractive features in the landscape. By a fortunate chance one of these banks with its original growth unimpaired still remains within the limits of the city of Boston and is included in the Arnold Arboretum. This steep hillside is shown in the illustration above. From the roadway which swings around to the right it is separated by a ravine through which flows a small stream and its dark mass of foliage and noble sky-line give a dignity to the entrance which is hardly excelled by that of any park in the world. Besides its effectiveness from an artistic point of view, this representative example of one of our most interesting forms of forest scenery is well placed at the vestibule of the sys-

tematic plantations in which are to be grouped specimens of every species, and well-marked variety of the trees that can be made to flourish here from all the cooler regions of the globe.

Shrub Propagation.

THE old adage, "What is one man's meat is another man's poison," seems especially applicable to the reproduction of hardy shrubbery. Not only each genus, but often each species, and in a few cases each variety, requires a separate method of propagation. For instance, the ordinary Snowball, *Viburnum opulus sterilis*, is of the very easiest manipulation, and strikes like a weed, and yet its Japanese relative, *V. plicatum*, is quite difficult to handle. Most Spiræas are easily propagated by cuttings, and yet the nearly allied *Exochorda* is exactly the reverse. All the Hydrangeas root readily excepting *H. quercifolia*, which is stubborn in this respect. The ordinary Quince emits roots with almost any degree of moisture, but cuttings of the Japan Quince refuse to do so under the most advantageous circumstances.

Most common shrubs, as Weigelas, Spiræas, Hydrangeas, Lilacs, Deutzias, Tamarisks, Viburnums, etc., are best propagated by soft-wood cuttings in midsummer, care being taken to secure the wood as soon as it begins to harden. This is the critical period, and on its observance depends success or failure. Cuttings 3 to 4 inches long, with two or three curtailed leaves at the summit and without any regard to a bud at the base, should be placed in shallow boxes filled with firmly pounded sand. A perfectly close, warm atmosphere, with an abundance of moisture and shade, will cause roots to form in a short time, when they may be gradually inured to the outside air. They will keep in the boxes until the succeeding spring if protected in cold frames.

The Japanese Snowball, *Viburnum plicatum*, from the peculiar nature of its wood, requires a long time to root, and should never be hurried nor deluged with water. The newly rooted plants must be potted singly as soon as possible, and permitted to remain in the house until autumn, when they, too, may be wintered in cold frames. Soft-wood cuttings taken from forced plants in winter root more quickly than those grown in the open air, but the young plants must remain in pots for a year. The weaker short-jointed side shoots always make the best cuttings, and will grow just as rapidly after rooting as those struck from vigorous leading branches.

Any shrub having underground stoloniferous branches, which are, of course, supplied with buds, should be increased by root cuttings, especially where other cuttings are difficult to strike. The Japan Quince, Oak-leaved Hydrangea, *Spiræa opulifolia*, *Philadelphus*, *Rubus* and *Rhus* are examples of this class.

Our stock of most hardy shrubs is most cheaply increased by hardwood cuttings, where an abundance of wood is obtainable, when the weather is not too dry. These may be cut into lengths of eight or nine inches from last year's growth, tied into bundles, and either buried at once in the open ground, or preserved in boxes of sand or moss during freezing weather. At the earliest possible moment in spring, they should be put into rows, in a well prepared piece of ground, and be well tramped about the base. *Exochorda grandiflora*, *Culycanthus floridus*, *Æsculus parviflora* (Dwarf Horse-chestnut), *Euonymus Europæus*, *Spiræa callosa*, *Berberis*, *Mahonia*, *Hypericum*, and some others, seed freely, and thus afford an easy and rapid mode of propagation. Seeds sown thinly in the spring in shallow frames, and covered lightly with brush, will as a rule germinate quickly, and form nice little plants in two or three years.

Divisions of large clumps is mainly practiced on plants difficult to propagate by cuttings, as *Clethra*, *Itea*, etc., or where an old specimen has to be removed, and two or three smaller plants are deemed preferable. Nothing is gained by planting so-called extra-sized shrubs. In the time usually required for such to recover from the removal, young thrifty plants equal them in size, and surpass them in vigor. The long tough stems of most old plants are averse to forming new branches, even when cut severely back, which is not the case with robust young stock.

Layering is generally a tedious process, and may not always be recommended when a large supply of shrubs is needed. Time is money to the nurseryman, and a few young plants gained by bending down the branches of some old specimen, are really of little moment. Still there are exceptions to the rule. By setting out several old clumps of *Magnolia obovata*, Purple-leaved Berberry, or Purple-leaved Hazel, the number of shoots increase with the age of the parent, and readily form roots after being nicked and covered firmly with suitable earth at the base.

Grafting shrubs is restricted to the skilled gardener, and is worse than useless in the hands of a novice. Although easily performed in Europe, owing to certain climatic influences, with us it requires great care and attention. Rhododendrons and Azaleas are necessarily increased in this way. To obtain a supply of the newer and attractive varieties of *Althæa*, some of our cultivators resort to ordinary whip-grafting. In two years' time, if not injured by the winter, the plants will be of fine size, and suitable for the market.

Foreign gardeners obtain a supply of the newer and rarer varieties of Lilacs, and some other shrubs, by grafting on small seedlings and covering them with a bell-glass, but in this country it is seldom practiced, owing to the amount of care necessary to make it a success. *J. Hoopes.*

Note on our Native Irises.

MANY old world Irises have long been and still are favorites in cultivation, but our own native species have received little attention from horticulturists, and most of them are imperfectly known even to professed botanists. As they are among the handsomest of our wild flowers they deserve the attention and study of cultivators and botanists alike. Of the genus *Iris* there are over a hundred known species, of which we have at least eighteen. These are equally divided between the region east of the great plains and that west of the Rocky Mountains. They may be grouped as follows:—

A.—Eastern and arctic species.

a. Dwarf; the only American species, excepting *I. hexagona*, which have either crest or beard.

I. LACUSTRIS; shores of Lakes Huron and Michigan.

I. CRISTATA; of the Alleghany Mountains.

I. VERNA; wooded hills and pine barrens, from Kentucky and Virginia to Alabama and North Carolina.

b. The *I. tripetala* group, having the inner petals very short.

I. TRIPETALA; pine-barren swamps of the southern Atlantic coast.

I. HOOKERI; on the lower Saint Lawrence River.

I. SETOSA; a Siberian species found in Alaska.

c. The *I. versicolor* group.

I. PRISMATICA (*I. Virginica*); the slender narrow-leaved species found mainly near the Atlantic coast.

I. HEXAGONA; a tall crested species of the swamps along the southern Atlantic coast.

I. CUPREA; with dull yellow or brownish flowers, in swamps of the inner districts from Southern Illinois southward.

I. VERSICOLOR; the common broader-leaved northern species, from Minnesota to the Atlantic and southward. This species is at present made to include all the forms that cannot be placed in the preceding. Among those forms (often tall and large-flowered) which occur in the Southern States, from Virginia westward and southward, there are some which are certainly distinct from the common Northern form, and perhaps from each other. A comparison of living specimens is necessary, however, to a determination of their distinctive differences.

B. Western species (not readily grouped by characters).

I. MISSOURIENSIS; the only species of the interior, ranging from the Rocky Mountains to the Sierra Nevada, and from the British boundary to Arizona and Colorado.

I. TENAX and *I. TENUIS*; a slender species of Oregon and Washington Territory.

I. MACROSIPHON, *I. DOUGLASIANA*, and *I. BRACTEATA*; of the Coast Ranges of Northern California and Southern Oregon; often low and slender, the flowers in the first two having a long narrow tube.

I. HARTWEGI; a low narrow-leaved species of the Northern Sierra Nevada.

I. LONGIPETALA; a stout several-flowered species of the coast from San Francisco to Monterey.

Few of these Western species have been studied from the living plants and they cannot yet be said to be well known, for in dried and pressed specimens not only the delicate colors but many of the other characteristics of the flowers are lost beyond recovery. But Irises are generally of easy cultivation, adapting themselves readily to a diversity of treatment, and it is much to be hoped that our enterprising florists and lovers of flowers will try their skill upon these our native beauties. They can thus have the satisfaction not only of working a new field which promises rich floral rewards, but also of giving essential aid to the botanist in determining more accurately the characters and limits of the different species. It may be added that Prof. Michel Foster, of Oxford, England, is making

Fig. 4. *Lilium Grayi*.

a special study of the genus, and for that purpose is endeavoring to obtain roots or seeds of all our forms from which to grow the plants in his own garden. Roots from any part of the country, and especially from the South and West, will be very acceptable and thankfully acknowledged, whether sent to him, or to the Botanic Garden, at Cambridge, Mass.

Sereno Watson.

Lilium Grayi.*

UPON the trip which Dr. Asa Gray made to the Alleghany Mountains in 1840 he collected upon Roan Mt., in North Carolina, a single specimen of a lily which was considered by him to be a form of the common *Lilium Canadense*, and as

such it was preserved in his herbarium at Cambridge. During the last ten years the same form has again been found upon the same mountain, though not abundantly, and it has also been cultivated in the Cambridge Botanic Garden. Though evidently related not distantly to *L. Canadense*, yet it differs from it so decidedly that it has been deemed deserving of specific rank and has been honored with the name of its discoverer. Its more striking characteristics appear plainly in the accompanying figure. As contrasted with *L. Canadense*, the flowers are smaller, less pendulous, and broader at base; the petals are broader in proportion, less tapering at the top, and not at all recurved; and the leaves are perfectly smooth, and usually broader and less narrowly pointed. In *L. Canadense* they are rough upon the edge and usually also upon the veins beneath, and sometimes over the whole lower surface. In this respect that species differs also from *L. superbum*. The flowers are dark colored, of a deep reddish orange, uniformly dotted within with rather small purple spots. In its native locality it blooms in June. The bulbs are like those of *L. Canadense* and *L. superbum*, renewed from year to year upon a perennial rootstock, and respond as kindly to a similar culture. The species has been found upon the Peaks of Otter in Virginia and probably occurs in many other places in the southern Alleghanies.

S. H.

*L. GRAY, WATSON, *Proc. Am. Acad.*, xiv, 256. Leaves in whorls of 4 to 8, lanceolate, acute or slightly acuminate, not at all scabrous; flowers often solitary, ascending, or somewhat nodding, broadly funnelliform, two inches long or less, the petals oblanceolate, abruptly acute, not recurved, deep reddish orange, spotted within.

American Thorns as Ornamental Plants.

THERE is a general impression that the native Thorns are valuable as ornamental plants, and yet they are rarely seen in private grounds unless they grow there naturally. There are two reasons for this neglect: the difficulty of transplanting and growing them, and the perplexing variations of the wild plants.

There is little difficulty in growing the Thorns from seeds if the seeds are stratified in sand as soon as ripe, and if the operator is willing to wait a couple of years for the appearing of the seedlings. When young, the plants are removed readily, but success is rare in removing large specimens which have never been transplanted.

The perplexing variations in the Thorns are among their most attractive features and render their cultivation all the more desirable. These variations have reference to size, color, shape, and season of fruits, to habit of growth and occasionally to leaf character. In certain species which occur in Michigan, notably in *Crataegus punctata*, the fruit is so inconstant that it cannot be relied upon for specific characters. Even yellow-fruited forms occur. In some individuals the fruit is nearly as large as a small Siberian crab, and is borne near the centre of the top, hanging in attractive maroon balls from the horizontal spray. In other specimens it is scarcely larger than a pea, and is borne much nearer the ends of the branches, which, in this case, are usually more upright than in the former variation. In short, so inconstant are the Thorn fruits, that the observing traveler in these parts is constantly

attracted and bewildered by them. Many, if not most of these variations, are not reproduced by seeds. In order to perpetuate them the grower should graft from them.

Good ornamental-fruited plants are not abundant. We find that the large-fruited Thorns drop their fruits early. This is due in part to the weight of the fruit and in part to the ravages of the codling moth and the plum curculio. The fruits of the best forms of the scarlet Thorn (*C. coccinea*) are especially liable to drop. We shall spray our plants with Paris-green water next spring. Of the Michigan kinds, the pear-fruited Thorn (*C. tomentosa*,) holds its fruits best. Up to Christmas all these ruby colored fruits remained erect, long after every other sort had fallen. The fruits are small, resembling a small rose-hip, and contain so little flesh that the worms do not trouble them. They are borne in clusters. Hereabouts the branches of this Thorn are nearly bare of leaves where the clustered fruit is borne, so that the autumn aspect of the plant is singularly attractive.

Thorns are attractive in fruit, in habit, in foliage and in flowers. Upon this classification I should place our Michigan Thorns, five sorts, as follows, in order of preference:—

FOR FRUIT: *C. tomentosa* var. *pyrifolia*, *C. punctata* (*C. tomentosa* var. *punctata*), *C. coccinea*, *C. Crus-galli*, *C. subvillosa* (*C. tomentosa* var. *mollis*).

FOR HABIT: *C. punctata*, *C. coccinea*, *C. subvillosa*, *C. Crus-galli*, *C. tomentosa* var. *pyrifolia*.

FOR FOLIAGE: *C. Crus-galli*, *C. coccinea*, *C. subvillosa*, *C. tomentosa* var. *pyrifolia*, *C. punctata*.

FOR FLOWERS: *C. coccinea*, *C. Crus-galli*, *C. punctata*, *C. tomentosa*, var. *pyrifolia*, *C. subvillosa*.

Michigan Agricultural College.

L. H. Bailey.

Plant Notes.

Milla biflora, Cav., in its Home.—By an occasional glance at horticultural journals, whenever returned to civilization, I have been gratified to learn that this plant, which I have admired in the wilds of North Mexico, is being brought into general cultivation. I had for two years seen it scattered over the grassy plains and foothills and even on the broader mountain summits about Chihuahua—the plant on the richer plains growing to a height of two feet and bearing half a dozen flowers, in the thinner, dryer soil of the mountain top less than a foot high with but a single flower—but, not until I reached the high plains about the continental divide and near the Cordilleras, did I find it in abundance. Here on broad swells were miles of prairie bespangled with its silver stars crowding upon a yellow-flowered Phlox and a purple Pentstemon. From a bulb one-half to three-fourths inch in diameter, planted two to four inches deep, it sends up a stem one to two feet high, bearing one to five flowers. Under good culture the size of the bulbs must rival those of some classes of Gladiolus, and a much taller stem must bear an umbel of a dozen flowers, whose size is proportionately increased. The fact that its flowers possess much endurance, and succeed one another in the umbel during many days, in the way of Agapanthus, must add merit to the plant. It should prove hardy, with a light covering of leaves, in American gardens, and would doubtless thrive best if thus wintered in the soil. The plant propagates itself by seed only.

Calochortus flavus, Shult. f.—Associated with *Milla biflora* in the drier situations we find this, another liliaceous plant of much beauty, as yet little known in gardens. On a branching stem a foot high it bears two to four, or more, nodding flowers, one to two inches broad, of rich crimson and gold and furred within. In a Northern garden the plant has shown even in one year much increase in its size and in the number of its flowers.

C. G. Pringle.

Caryopteris Mastacanthus, Schauer.—Among the novelties of late years this beautiful shrub, introduced into Europe by Veitch & Sons, deserves special notice. A native of China, its hardiness was doubted at first, but it has done very well in a dry, sunny position; as well at Baden-Baden as in England. It is a much-branched shrub of a sturdy appearance much like a Ceanothus. Along the branches and branchlets, wherever there is a leaf, a little bunch of small starry flowers is produced, assuming an umbellate form and decorating the whole shrub with deep blue. It flowers here about the middle of October, when flowering shrubs are quite as rare as blue flowers. Planted against a low wall and left to grow at will, all passers-by are struck with its beauty.

Baden-Baden.

Max Leichtlin.

(This plant was discovered by Fortune in Southern China, and is well described in De Candolle's *Prodromus*, xi. 625. It is a native also of Japan, where it is said to grow on the borders of old fields and on the summits of mountains. It is from Japan that the Messrs. Veitch introduced it into cultivation, and there is a prospect, therefore, that it will prove hardy in the United States. A good figure of *Caryopteris mastacanthus* appeared in the *Gardener's Chronicle*, xxi. n. ser., 149. It belongs to the Verbenaceae family.—Ed.)

The Red Mite on Verbenas.

THE two packages of Verbena sent by Mr. Peter Henderson to the office of GARDEN AND FOREST, one containing young, healthy plants, and the other those which have been dwarfed and crumpled by the attacks of the mite, illustrate well the work of this pest. We could not find any full-grown specimens, but only the very small young, which were of a pale yellowish color.

The red mite, erroneously by some called the red spider, is one of the few mites which spin a web. When we examine the mouth parts it will be seen how well adapted it is for cutting into and sticking close to leaves; its jaws, like those of seed-ticks, form a spiny beak, with the points directed backwards; with this beak it can anchor itself in the soft parts of the under side of leaves, while with the forceps-like feelers it can eat its way into the leaf, or grasp surrounding hairs or projecting parts of the leaf and steady itself while sucking the sap of the plant. Its presence may be detected by the slight web, the blighted, pale patches on the leaf, and sometimes, as in the examples before us, by the striking alteration in the leaves and the dwarfed appearance of the plant.

A general pest of Plants, both in the hot-house and in the garden, when it varies much in color, most of them when fully grown being greenish to rust-red, sometimes quite dark, the creature propagates rapidly, and abounds most in hot, dry seasons, moisture being unfavorable to its growth.

As to remedies, it should be borne in mind that all mites are very susceptible to sulphur, hence as a preventive measure laying flour of sulphur upon the pipes in the hot-house has been recommended. It would also be well to underspray the leaves of infected plants with such a solution of sulphur as would cause the powder to remain on the leaves. Spraying machines are the most efficient means of rapidly and evenly diffusing insecticides of all sorts, though we have not heard of their use in

Red Mite (*Tetranychus telarius*).
From Saunders' "Insects Injurious to Fruits."

the hot-house. Finely powdered tobacco, or even Paris green or London purple in solution, the latter carefully applied with the sprayer to plants not in flower, would be worth trial.

Nearly all mites, like all insects, breathe through minute openings in the sides of the body, hence any oily or greasy substance which, spreading over the body, will form a film over the air-holes, will kill the creature; it is soon asphyxiated or drowned. For this reason greasy or oily substances are the most powerful and sure insecticides. Oily emulsions, even cotton-seed, or any other vegetable oils, could easily be used in hot-houses; kerosene emulsions should be used with care, and only after experiments, so as not to injure the plant itself, since mineral oils are most destructive to plant-life. Perhaps underspraying with whale-oil soap or sulphur in solution is the readiest and most available remedy, but it would be worth while to experiment with the Paris green or London purple solutions, also kerosene emulsions, which have proved so successful out-of-doors; always bearing in mind that frequent showerings with soap-suds or water alone, by which the leaves are kept wet, tends to prevent undue increase of the pest. Mr. Henderson thinks he has discovered a complete remedy for this pest in the use of manure water. The increased vigor of the plant under this treatment seems to enable it to outgrow the ravages made by the mite.

A. S. Packard.

Cultural Notes.

Primula Obconica.—This is a comparatively new Primrose, a native of China, and one of the sweetest and loveliest, and so far as I know, the most free and continuous blooming of the genus.

It was discovered in the neighborhood of Ichuny, Central China, by Mariés, collector for Veitch, of London, and first bloomed in cultivation in the Veitch nurseries in September, 1880. In the *Botanical Magazine* (tab. 8582), 1881, it is figured and described under the name of *Primula poculiformis*. In *The Garden*, September 6th, 1884, there is an excellent colored plate of it prepared from an English garden-grown plant.

Soon after its *début* into English gardens it found its way to America, and so well has it behaved that it has become a fixed favorite wherever grown. Indeed, so favorable an impression has it made that one florist near Boston has made a specialty of it for cut flowers, and the Boston seedsmen this year offer it as their most important novelty.

We have it here and are exceptionally well pleased with it. We treat it as a cool green-house pot plant, and find that it is of the easiest possible culture, free growing and continuous blooming, and may be treated as an annual or perennial. Veitch speaks of it as "flowering continuously and profusely from spring to autumn," and recommends it "during the summer months for the open border." Some plants procured two years ago have been in bloom continuously ever since then and have more flowers now than they have had at any time previous. I sowed some seed last spring, it germinated in about two weeks, and the seedlings have grown and flourished. They began blooming in August and have been in full bloom ever since.

The foliage much resembles that of *P. cortusoides*, a Siberian species grown in our gardens as a hardy perennial, but is not deciduous. The flowers are white to pale mauve-purple, showy and sweetly fragrant, and are borne in loose umbels on tall scapes that rise well up above the foliage; and in thrifty plants the umbels have an inclination to break off into whorls after the fashion of the inflorescence of *P. Japonica*. The blossoms last well as cut flowers, and the plants make excellent house or window plants. During the summer months our plants set seeds freely and without any artificial assistance, but since winter began no seeds have set except where artificial assistance has been given. *W. F.*

Leptosyne Maritima.—A perennial composite with succulent stems and much divided fleshy leaves, and large showy bright yellow flowers produced singly at the ends of long slender stalks. The plant is indigenous to "Sea beach at San Diego, and on the islands."

I have grown this plant for a good many years, out-of-doors in summer and in the green-house in winter. Although it is a perennial it is treated as an annual, it begins to bloom when about four months old, and so long as it continues in good healthy condition, so long it will continue in bloom.

Planted out-of-doors in summer it grows and blooms prettily, but here it does not bear as fine flowers as it does in the green-house in winter. Our plants are in six-inch pots, in a sunny green-house, with a night temperature of about fifty degrees, and they now have been in full bloom for more than three months. This *Leptosyne* loves sunshine and will not thrive in the shade; and it very much dislikes a close, moist atmosphere or an over-wetted soil.

The blossoms are well adapted for cut flowers and last in good condition for several days after they have been cut; but as they are apt to partially close up at night this weighs heavily against them.

L. Stillmani and *L. Douglasii* are both Californian annuals, pretty enough in their way, but small and short-lived, and without anything of the bold, showy character of *L. Maritima*. *F.*

Carnations.—James Y. Murkland is the brightest scarlet we have, but the flowers are not full and solid enough or the plants sufficiently abundant or enduring to justify its use as a main crop. Portia is our stand-by for scarlet. It is early, continuous, a great cropper and the flowers do not burst. Among scarlets, E. S. Hill gives superb promise. The plants are vigorous and the flowers unusually large. Marshal P. Wilder has very large flowers, but they are short-stemmed and the calyx bursts. My best white is Hinzy's. Started early and not pinched after June it begins to bloom in September and lasts in good condition till February. Peerless, Snowdon and De-graw do not do well here. Neither do Buttercup nor Astoria among yellows. Lydia, yellow striped with pink, is the best of its class. Columbia, after the same fashion, but with narrower

stripes, is an abundant bloomer, but the flowers are not very firm. La Purite, carmine, is a capital grower, and it blooms freely too, but the flowers burst a good deal. Charles Henderson, tall and very copious, has carmine fringed flowers, rather small, but of capital form. Kaiser William has violet purple flowers of good form and striking in color, but many ladies object to the shade. Petunia is a slender grower, but it bears a good crop of rose purple and white full double, though often ragged, flowers, which are much esteemed by ladies. Crimson King used to be our mainstay in its class, but it is beginning to fail. Black Knight still holds good. It is of slender growth. It blooms sparingly in fall and early winter, but as January advances it waxes in strength. Gibbonsii is the largest and finest of all our crimsons, but it is a late-blooming one-cup variety. May Queen, bright rose, is a lovely, perfect flower, and unlike most varieties of its class, the color of whose flowers soon fades, its flowers retain their bright color for several days after they have been cut. While Grace Wilder is a very pretty carnation and of a desirable shade of blush, the color soon fades. This variety is often rather refractory. *W. F.*

Brodicea (Triteleia) Uniflora.—This charming Liliaceous plant we grow in pots for decoration of the conservatory. For this purpose it is very valuable, especially at this dull season of the year, besides being very pretty. It flowers in great abundance (as many as fifty flowers may often be had in five-inch pots) and will last a long time in perfection. We give them the usual treatment of this class of Bulbs, viz.: good rich soil in well drained pots, liberal watering while growing, gradually drying off for the summer months and repotting in the fall. There are two or three varieties of this species, one a pure white. It was introduced from Buenos Ayres in 1836. *F. G.*

Grapes Under Glass.

OUR early vinery contains, mostly, Black Hamburg; our medium, Muscat of Alexandria; and our late, Lady Downes, which I think is the best of all late grapes. Lady Downes, Black Alicante, Gros Colman and other late sorts will succeed pretty well when grown in the Muscat house, but I much prefer growing them in a house by themselves. I have Alnwick Seedling growing in the same house, and alongside of Lady Downes. It sets as freely as does a Black Hamburg and produces large blue-black berries and bunches of three to seven lbs. each in weight, but the grapes do not keep long after they are ripe. Indeed, I have, every year, to begin cutting them before I have cut half of our Muscats. Except for exhibition purposes I do not regard it favorably, but it will make a good enough stock on which to inarch more serviceable sorts. Black Alicante like Lady Downes always hangs on the vines plump and fresh till New Year's. Pearson's Golden Queen is a good-looking grape, but of little merit except for exhibition. After having given it a fair trial, both as an early and a late grape, I have concluded to discard it.

After the fruit is ripe in the Muscat house I bring *Dendrobium Wardianum* and others of its class into it to ripen their flowering pseudo-bulbs. I also use the earliest vineries for Chrysanthemums in the fall, but I never bring these in before all the grapes are cut, and I remove them before we begin to give our vines their annual cleaning. On no account do I ever allow any plants to be kept in or brought into the Lady Downes house, as the extra moisture they would induce would be detrimental to the keeping qualities of the grapes, which we wish to have in plump and good condition as late as possible—usually till January. I never permit any bedding or miscellaneous green-house plants, apart from those mentioned above, to be kept in any of the graperies under any circumstances, so as to avoid all possible chance of the introduction of mealy bugs or other insect vermin.

Of recent years we have discontinued the use of the syringe in our vineries except in the case of our earliest house, and in that we discontinue syringing as soon as the grapes begin to color. After the fruit is cut from it, however, we give the vines a few heavy drenchings of a solution of whale oil soap and tepid water—about two ounces of the soap to the common wooden pailful of water, and applied about sunset.

On account of the small amount of fire heat we use to help ripen the fruit and wood, we are not troubled with red spider.

We use tobacco stems as a preventive against thrips, placing them on the border between the bottom ventilators and the front row of pipes, and in this way use at one time a barrel of stems to every sixty feet in length of house. We renew the tobacco stems three times during the summer, and each time have them fresh from the cigar factories.

David Allan.

The Lawn.

NOW is the time to attend to the lawns. If they have been top-dressed with manure or compost over winter, on some fine dry day when it is not frozen, go over the lawn with wooden-toothed rakes and spread the dressing equally over the ground. Then repeat the operation and rake off all sticks, stones and other rough things that may have been in the dressing, but do not rake off any of the manure except where it may be so heavy as to threaten interference with the mower in summer. If this is done now, there will be no fear of the grass bleaching under the manure where it has fallen in lumps, but if delayed till the grass begins to get green it will bleach, then sun-scald and look patchy.

Lawns that have not been top-dressed should also be raked over with close-toothed wooden or iron rakes, so as to clear off the loose dead grass and other *débris* that would interfere with the mower. In raking the lawns be very particular along the borders of roads and pathways, where small stones may have been thrown up on the turf.

If the dead grass is long or shaggy burn it off. This may be heresy in the eyes of theorists, but experience has proved it to be good practice. The burning does not injure the crowns of the grass in the least degree nor destroy a particle of the nutriment on the surface of the ground, but it effectually gets rid of the dried grass, which, if not removed, would clog the mowers and weaken the young shoots in coming up.

If the surface of the lawn has any depressions fill them up with loam. These may be the foot-prints of men or animals made when the ground was soft. And some morning when the lawn is wet and soft go over it with a heavy roller to make the sod smooth and even; but never use horses in the roller when the lawn is in this condition, as their feet would leave deep impressions in the ground. With two men and a hand iron roller all the grass in the narrow places, as between the trees and shrubs, can be reached, and in the open spaces eight men to a large iron roller do capital work.

Many spots in the lawns will need patching. Where trees or rocks, in former years, have been dug out, the earth may have sunk so as to form a hollow; fill up such places with loam, and resod. And where little hillocks occur on the lawns, shave them down and replace the sod.

Sometimes weeds kill out the grass. The most destructive of these pests are Yarrow, Mouse-ear Chickweed and Sorrel. They kill out broad patches, and can only be overcome by being dug under or cut out, and again resowing or sodding the ground to grass. Crabgrass is almost invulnerable. So long as we keep our lawns smoothly shaven we cannot subdue it, for in September and October it spreads its wiry stems along flat on the ground and perfects and scatters its seed for the next season's work. The only way to get rid of it is to pasture the land or so encourage the lawn grasses to grow that they shall choke it out.

Where the lawn is mossy, as in the neighborhood of trees, or rather bare of grass caused by impoverished land or drought, remove the moss with a sharp long-toothed iron rake and loosen the surface of the ground; then topdress thinly with rich earth, and sow some red topseed on it, rake it in and roll firmly.

Where it is needful to do repairing, as for example, to mend the borders along the roadsides, to cover places caused by recent tree removals, to turf over beds, mend banks about the house, and the like, always use sod in preference to grass seed. Where much sod-laying has to be done a sod-cutting machine should be used, but in small places where the sods are cut with a spade never let two or more men work for the same piece of ground, as no two men cut sods alike. With the ground properly prepared and leveled, and the sods all equal in thickness, length and width, in laying them it is an easy matter to make a neat piece of work. All sodding and seeding should be done as early in spring as possible, in order that the grass may be well up and have a good hold upon the ground before the warm dry weather sets in.

William Falconer.

DO NOT HURRY to uncover the Roses, Strawberries and other plants that you have protected over winter. A few bright, warm days in March is no indication that the winter has completely retired; the frosty, searing winds of March are more injurious to plants than is the zero weather of January.

GARDEN LABELS.—The frost will have thrown many small labels out of the earth and we will now find them lying on the surface of the ground. If this is neglected the wind will blow them about. Stick them into the ground where you find them lying.

The Forest.

Forest Trees for California.

A GLANCE at the forest map of California, given in Vol. 9 of the Report of the Tenth Census, shows that there are in the State but two compact bodies of timber; that of Pines and Firs covering the higher western slopes of the Sierra Nevada, and the Redwood belt stretching along the western portion of the Coast Range, from the bay of Monterey to the Oregon line. The lower foothills of the Sierra, and the plateaus and northern slopes and cañons of the Coast Ranges, bear a scattered growth of timber; but neither the quantity nor the quality entitles it to be counted on for more than a scanty supply of firewood, after the needs of the first settlers have been met. The great valley, and the adjacent slopes on either side, are practically treeless, except along the courses of the streams, and on the exceptional area formed by the delta of the Kaweah River, in Tulare County, which is covered with quite a compact growth of the White Oak (*Quercus lobata*). A scattered growth of the same Oak prevails in most of the Coast Range valleys, outside of the Redwood belt; on the rolling lands near the coast, it is intermingled with the California Live Oak (*Q. agrifolia*) and the Black or Sonoma Oak (*Q. Kelloggii*). Along the Sierra foothills it mingles with the Blue Oak (*Q. Douglasii*); higher up it disappears and the Blue Oak with the two mountain Live Oaks (*Q. Wislizeni* and *Chrysolepis*) and the Foothill or Digger Pine (*P. Sabiniana*) prevail. These, with occasional groups or individuals of the beautiful Madrone (properly Madrono—*Arbutus Menziesii*), a few Firs on the higher levels, and in the cañons the large-leaved Maple (*Acer macrophyllum*), the Box Elder, the large Alder (*Alnus oblongifolia*), and last but not least the Laurel (*Umbellularia Californica*), constitute the common tree growth of Central California that, outside of the timber belts first mentioned, might be expected to serve the common uses of the deciduous forest trees of the Atlantic slope. To these are added, in the northern portion of the State, a part of the Conifers of Western Oregon; while in Southern California, a number of trees mentioned above are wanting, or but feebly represented, and the mountains as well as the valleys are as a rule scantily timbered, and largely quite bare of trees.

Even were these trees mentioned as well adapted to the uses of every day life as those of Eastern deciduous forests, their relatively scanty occurrence within that portion of the State best adapted to dense settlement would render the maintenance of the timber supply a question of the most pressing importance. But as a matter of fact the wood of most of the native non-Coniferous trees, and especially that of the lowland Oaks, subserves but indifferently any purpose save that of fuel. Not only have the trees as a rule a very low trunk, beginning to branch from seven to fifteen feet above ground, and often losing the leader; but even the "clear" wood is mostly so brittle and its grain so uncertain that to split it into rails, clapboards or staves is out of the question. When a tree is broken off by the wind, instead of the long, elastic splinters projecting from both ends, we find rough, jagged breaks almost square across. Of the California Live Oak, the wood-choppers sometimes state with mild exaggeration that it splits crosswise about as readily as lengthwise. The White Oak is a little better, and like the Blue Oak is sometimes used for fence posts; but even in this dry climate they show little durability as such. Only the mountain Oaks can to a certain degree subserve the ordinary purposes of hardwoods; and no Californian tree, save perhaps these, could be successfully worked into axe helves, hoe handles, or other agricultural implements of any durability. The Maple, Ash and Laurel are to some extent used for furniture and inside finish, but not where strength of material is required. Practically all the hard woods used in California must be imported, and at present come from the Eastern States; a small part, for cabinet and decorative work, from Mexico.

It is thus natural that when trees have to be planted, the preference should be given to such as are likely to supply this great need, and it is equally natural that the first thought should turn toward the familiar Eastern forest trees that serve these purposes so well. Thus the seeds of the Hickories, and of the White and other Eastern Oaks, soon found their way into private grounds and nurseries for trial. It may be broadly said that the outcome of these experiments (repeated since on the experimental grounds of the University of California) has been eminently unsatisfactory. The young trees not only refuse utterly to avail themselves of the longer growing season for more rapid development, but show a perverse disposition to branch out low and form bushes without a definite trunk; and when pruned up with a view to forming a single strong trunk, will sometimes return to first principles by sending up shoots from below. I doubt whether there exists at this time in the State, a specimen of an Eastern Oak or Hickory that would not have been better developed almost anywhere east of the Mississippi River, at the same age.

Not all the deciduous forest trees of the Atlantic States, however, behave in this way. Thus the Cork Elm, the Linden, several Maples, the White-wood (*Liriodendron*) and some others, develop normally, and some of them somewhat more rapidly than in their native clime. But none of these can properly fill the gap left by the Oaks and Hickories; and hence, substitutes for these have been sought in other climates, notably in Australia, whose rapid-growing *Eucalypts* and *Acacias* have already acquired a wide distribution in California. Oddly enough, some trees from diametrically opposite climates seem also to adapt themselves to that of California, and most promising among these, at the present time, is the European or "English" Oak (*Q. Robur*, var. *pedunculata*).

E. W. Hilgard

Growing Deciduous Forest Trees from Seeds.

WE sow all of our tree seeds in Spring, and as the following rules are based on our own experience, they all apply to spring sowing.

WHITE ASH seeds ripen in early October, and fall after the first severe frost. They should be mixed with moist sand, and not allowed to become dry before sowing. This same treatment should be followed with all the native Ash family with one exception, viz., the Green Ash, which hangs on longer and will germinate if sown dry; all others will remain dormant until the next season, if sown dry.

HARD MAPLE seed ripen early in October, and require the same treatment as the White Ash.

SOFT MAPLE seeds ripen in spring immediately before, or about the time, that Apple trees begin to blossom. They should be sown within a few days after gathering.

ELM seeds ripen in spring, and they require the same treatment as those of the Soft Maple.

BLACK WALNUTS, and all nuts with a pulpy covering, may be spread in thin layers, say six inches deep, and covered with sods and litter to prevent drying during the winter, in which case the pulpy covering will be easily disposed of in spring.

Other *Nuts* and *Acorns*, together with seeds of the *Tulip tree* and *Basswood*, are safer treated as recommended for Ash and Hard Maple seeds.

CATALPA and AILANTHUS seeds are kept dry during winter and sown rather late in spring.

BIRCH and ALDER seeds are kept dry, and sown dry early in spring.

LOCUST seeds and those of all that family are kept dry through winter and soaked in hot water immediately before sowing.

All seeds with a fleshy covering, such as Apple, Cherry, Mountain Ash, Cucumber tree, Buffalo Berry, Red Cedar and Holly, are washed free from the pulp, mixed with sand and sown in spring. We make an exception generally with the Red Cedar and the Holly, as they never germinate evenly in the spring, therefore we bury them in a rot-heap during two winters and one summer, and sow the following spring.

POPLAR and WILLOW seeds are very fine and delicate, and require skill, close attention, and continual moisture during the early part of the season. Therefore it is cheaper and surer to raise them from cuttings than from seeds.

All seeds mixed with sand must be placed so that water will not stand around them. Frost will not injure them, unless in a position where they will freeze dry. A cool shed where they are protected from sun and wind, will be a proper place.

Robert Douglas.

Answers to Correspondents.

Cutting down Chestnut seedling trees from sixteen to twenty inches in diameter, I find them rotten at the heart. What is the cause, and how may I know when the decay begins?

Sharon, Conn.

J. L. D.

The disease known as heart-rot, and under other names, which produces a decay in the centre or heart of trees, mostly older trees, is caused by various fungi, which attack the tree either from the root or above ground. While the precise progress of the disease is not yet fully understood, there seems no doubt, that other causes predispose the tree for the attack of the fungus; a dying or dead root, or the stump of a broken branch give usually entrance to the mycelium of the fungus. Unfortunately, neither the beginning nor the progress of the deterioration, which is the consequence of the fungus growth, is readily observed, since the tree, attacked only in the old, inactive wood, shows no outward sign of interior disease in its general appearance, and the fungus may do its destructive work for years without fruiting, by which alone it makes its existence apparent externally. Whenever a fungus (fruiting) appears on the stem, especially on the scar or stump of a broken branch, or near the foot of the tree, it is usually the sign of a heart-rotten tree. This disease is often the consequence of injudicious pruning of older trees, and should induce a more careful use of the pruning knife; shallow soil with hard-pan subsoil, especially if subject to overflow, is also conducive to this disease and necessitates earlier utilization of the timber to avoid loss.

B. E. F.

Recent Publications.

Gleanings in Old Garden Literature, by W. Carew Hazlitt. New York: George J. Coombes, 1887. Reprinted from the English Edition.

This book on Old English Gardens is a charming new volume—one of that charming series called *The Book Lover's Library*, which is issued in England, but also in New York, by Mr. George J. Coombes.

It is a small volume, written in a bright and unpedantic style, yet the amount of curious information it contains is immense. Early herbals and physic gardens, kitchen, window and cottage gardens, and orchards are described, together with methods of bee-keeping and wine-keeping. The herbs and vegetables, the flowers and trees which the Englishman of former generations loved, are named. Bacon as a gardener has a chapter to himself. The way in which Bacon and Shakespeare spoke of the Strawberry forms the text for a delightful little essay. Elizabethan gardening, the French and Dutch schools, Evelyn and his "Sylva," Walpole and the gardeners of the eighteenth century—all these are successively discussed by the aid of numberless citations from rare and quaint publications; and, in short, nothing which relates to the craft of gardening or the love of flowers and plants in the olden time has been overlooked by this industrious yet lively author. The wide extent of his acquaintance with the by-paths of literature is proved on every page, and a valuable bibliography of English works on gardening published between 1603 and 1800 brings his volume to a close. As an appendix he adds, moreover, a reprint of Gibson's "Account of the Gardens in and round London," which was written in 1691.

It should be explained that Mr. Hazlitt's book contains small reference to gardening as an art in the wider sense—to what we call to-day Landscape Gardening. Individual plants and the methods of cultivating them are his concern, and the old books which would be most useful to the landscape gardener have no place in his lists. But within its own field his book seems complete, and it should find a place on the shelves of every horticulturist who has a soul for the history and literature of his favorite recreation and an eye for a pretty volume.

Flora Peoriana. The Vegetation in the Climate of Middle Illinois, by Frederick Brendel; pp. 1-89; Peoria, 1887.

We cannot do more than call attention to this interesting paper, the result of thirty-five years' study of the vegetation of a small area of about thirty-five square miles, by an excellent botanist and observer of nature, who explains in his preface that "it is intended to show how local floras should be treated to be useful to phytogeography; how notice should be taken of soil and climate to understand the vegetation of a certain

floral district." The hope that the author expresses that this publication will lead to similar studies in other parts of the country will be shared by all students of geographical botany.

Shade and Ornamental Trees Suitable for Cultivation in Queens Co., N. Y., by William Falconer. Reprinted from the Annual Report of the Queens County Agricultural Society, 1887; pp. 21.

This is not, as might have been expected from the title, a mere list of trees hardy on Long Island, but a carefully prepared essay on ornamental and street planting, with suggestions of the best trees to be used in different situations and for different purposes and with many sensible cultural directions which planters will find useful. It is pleasant to note that Mr. Falconer is a firm believer in the ornamental value of our native trees.

Trees of Reading, Mass. Part I.; by F. H. Gilson; Reading, 1888.

Mr. Gilson has had the happy idea of photographing and collecting historical information and valuable statistics in regard to the most remarkable trees growing near his home, and the still happier idea of allowing the public to share in the results of these studies. Part I. of this work now published contains beautiful heliotype portraits of five trees with accompanying letter-press. The Sassafras No. 2, with a trunk girth at the ground of 10ft. 3in., will probably prove to be the finest specimen in the Northern States, and No. 4, the "Nehemiah Bancroft Elm," is as noble a specimen of the American Elm as is often seen. Very fine, too, are a second Elm and a wide-branching White Oak. The cultivated cut leaved weeping European Birch, which completes this first series, seems out of place in this company, and such a work might more wisely be devoted to native trees. Of these there are still many noble specimens left in different parts of New England, and Mr. Gilson will confer a real benefit upon all tree lovers if he will extend the field of his studies to other parts of the country.

Public Works.

Tree Planting on Boston Harbor.—An interesting report has lately been made by Mr. Frederick Law Olmsted to the Commissioners of the Boston Department of Parks on the subject of planting the islands and headlands of the Harbor. The shores and islands are characterized by great variety of form, and they are picturesquely disposed, making intricate straits and vistas opening towards the ocean. One drawback to the attractions of the Harbor is the bleak aspect of the bluffs and islands, and it is plain that if they were wooded or clothed with foliage or verdure of any kind the scenery would be much more agreeable. On even the most exposed and rocky of these islands stumps remain to prove that they were once tree-clad, but since they have been cleared, a second growth has been prevented by pasturing animals. Deprived of forest protection the land has been losing fertility, as it has been exposed to the winds and salt spray, and the Harbor is every year being despoiled more and more of its original beauty. It is thought that if trees of the species which formerly flourished here were planted with suitable undergrowth they might help each other to endure the hardships of the place. In a very few years these young plantations would give a pleasing softness to the elements of the scenery which do not contribute to its picturesque ruggedness. When the plantations have attained a full-grown forest character the broad masses of foliage will lift the skylines of shores and islands, add to their variety of tint, and deepen their shadows. Of course such trees as are usually planted in lawns, parks and cemeteries could not be used successfully, but Mr. Robert Douglas, who has had a wide experience in planting trees under trying conditions, and who has studied the Massachusetts coast plantations made by Mr. Joseph S. Fay and others, has faith in the project and offers to take a contract to carry it out. Mr. Douglas will engage to plant the entire area, some 400 acres in extent; to care for the trees until they are well established, in thrifty condition and shading the ground completely, so that they will need no further cultivation. Payment is to be made in installments, the last one, sixteen per cent. of the whole amount, due only when 800,000 trees are certified by qualified agents appointed by the Park Department to have been found on the ground well rooted and thrifty. By the terms of such a contract the young trees would have the care of one of the most successful planters in the country during the most critical period of their history, and the risk to the city would be reduced to its lowest terms. It is thought that \$5,000

a year, for six years, to be used at the discretion of the Park Department, would be sufficient to insure a substantial success.

Flower Market.

NEW YORK, *March 2d, 1888.*

There is a decline in the price of flowers, excepting in a few sorts which appear unusually well grown. Weigela is the novelty of the week, it having been forced by a New Jersey plantsman. It sells for 25 cts. a long spike, and is highly esteemed by decorators. Hybrid Roses are plentiful, but their average quality is not satisfactory. The choicest are sold for \$1 each. Baroness Rothschild and Mabel Morrison have appeared. Selected American Beauties are also \$1. The favorite Gloire de Dijon Rose arrives in limited quantity and sells for 50 cts. a flower. Puritan Roses sell for 50 and 75 cts., and La France from 25 to 50 cts., according to quality. Perle des Jardins, Niphetos and Souvenir d'un Ami are down to \$1.25 a dozen, and Brides bring 20 and 25 cts. a flower. Maréchal Niel Roses are to be had for from 25 to 50 cts., the latter priced ones including a bud. Acacia has never been so plentiful and low-priced. It brings one-third less than it did last season. A good-sized branch may be had for \$1, and 25 cts. will buy what is termed "a spray." Carnations are selling for 50 cts. a dozen, excepting such varieties as Grace Wilder, Buttercup, Dawn and Harrison, which, when long-stemmed, sell for 75 cts. a dozen. Spikes of Mignonette, very large and beautiful, bring 35 cts. each, and smaller spikes cost from 10 to 25 cts. Callas are 30 cts. each, and Longiflorum Lilies from 40 to 50 cts. *Lilium Candidum* has just appeared, and sells for \$2.50 and \$3.50 a dozen. A single stalk with two flowers and a bud sells for 50 cts. Violets cost from 75 cts. to \$2 a hundred. The latter is the fancy price for those fresh-picked and brought in at certain hours daily. French Marguerites are of two qualities, those small, with fragile stems, which cost 25 cts. a dozen, and those of twice the size, on firm long stems, which bring 50 cts. a dozen. Double Tulips are in more active demand than other varieties. Tulips remain as last quoted, as do other flowers not mentioned above. *Asparagus plumosus* is used more freely than ever before because in greater supply. *A. tenuissimus* has somewhat given way to the former variety in popularity. For yard lengths *A. plumosus* costs \$1, and *A. tenuissimus* from 60 to 70 cts. Smilax brings 40 cts. a string. The cut flower trade has been active since the second week in Lent, Jewish weddings, dinners and luncheons having kept business stirring. Orchids are in steady request for table decoration. They do not fluctuate in price. They are to be ordered from all the first-class florists, but a variety is only kept on hand by those who have growing collections. Prices range from 50 cts. to \$1 a flower, and for sprays from \$2 to \$5.

PHILADELPHIA, *March 2d.*

The demand for flowers the past week has been fair, for the Lenten season. Jacqueminot Roses are more plentiful, prices ranging from \$3 to \$5 per doz. Mrs. John Laing is becoming more abundant, selling at the same price as Jacqueminots. Anna de Diesbach and Magna Charta may be had in limited quantities at from \$4 to \$6 per doz., but these darker shades of pink are not so popular in this city as the more delicate tints, like those of Madame Gabriel Luizet or Mrs. John Laing. American Beauty is preferred, when the darker colored sorts are required. *Asparagus tenuissimus* is not popular here. This is difficult to understand, because it is so delicate and lasts so long for room decoration. For festooning about mirrors few plants are more effective. Gardenias may be had in limited quantities at 25c. each. Marguerites and English Daisies are in fair demand at 25c. per doz. Perles have been overdone this season. Sunsets are more popular.

BOSTON, *March 2d.*

The weather has been wintry during the week and while it continues cold there will be little change in the prices of cut flowers. Some varieties of Roses, especially La France and Catherine Mermet, have been really scarce, an unusual feature of the market at this season. Violets are abundant and consequently cheap. Pansies are also becoming more plenty and the quality was never better. Long stemmed Carnations have seldom been seen here in such perfection and variety as at the present time. They are gaining rapidly in popularity, for buyers are beginning to appreciate them and are learning that there are few varieties of flowers which will keep so long in a warm room. Its own foliage is of course the best setting for the Carnation. Daffodils, Tulips and Lilies-of-the-Valley are still offered in large quantities. Great vases of Callas and *Lilium Harrisii* make a grand display in all the florists' windows and are a reminder that Easter will soon be upon us. Spiræa and Deutzia, which are always grown largely for Easter, are also beginning to come in in moderate quantities. The best Jacqueminots and Hybrids can be had now at from \$4 to \$6 per doz. La France, Catherine Mermets and Marechal Niels at \$3. Perles des Jardins and Niphetos at \$1.50 and the small Teas at 75c. per doz. Hyacinths and Tulips cost 75c., and Lily-of-the-Valley and Trumpet Narcissus \$1 per doz. For finest long-stemmed Carnations 75c. per doz. is asked, while Pansies, Mignonette, Calendulas, etc., can be had at 50c. per doz. Callas bring 15c. to 25c. and Harris's Lilies 35c. each. A fine box of choice Orchids with a slight sprinkling of Maiden-hair Ferns, Asparagus and a few dainty sprays of Heath, makes a superb gift and costs from \$25.00 to \$50.00.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.
[LIMITED.]

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, MARCH 14, 1888.

TABLE OF CONTENTS.

	PAGE.
EDITORIAL ARTICLES:—The Future of our Forests. Hardy Rhododendrons. Sir Joseph Hooker Tribute to Asa Gray.	25
Laws alone Cannot Save our Forests. J. B. Harrison.	26
Landscape Gardening, III. Mrs. Schuyler Van Rensselaer.	27

The Future of Our Forests.

THE forests of the United States play an important part in the economy of the nation. Their annual product far exceeds in value any of our great staple crops of the field. The gold and silver mined in the country is insignificant in value compared with the money value of the forest crop. It is difficult to picture the commercial and agricultural ruin which would follow any general disturbance of the productive capacity of our forests. No other country could supply us with the material we should thus lose, and we should lose, too, something more important even than the material they yield. Forests are often much more than storehouses of growing timber. They are essential in some parts of the country to insure the integrity of mountain slopes and the preservation of important rivers; and the destruction of mountain forests is invariably followed sooner or later by serious physical calamities.

The forests of this country are rich, varied and extensive. They still contain vast stores of many valuable timbers. In some of the most important forests serious inroads, to be sure, have already been made, and the practical extermination, from a commercial point of view, of some of our most valuable timber trees, now seems inevitable. Much of our country nevertheless is perfectly suited in soil and climate to rapid and vigorous tree-growth. The forests which once extended in an unbroken sweep from the Atlantic to beyond the Mississippi and which still cover the great mountain ranges facing the Pacific, clearly show the capacity of this country to produce forests unequalled in value by those of other parts of the world. It is only in the interior portions of the continent, insufficiently supplied with moisture, where the forests are scanty or altogether wanting, that their reproduction and extension offer any serious difficulties. Everywhere outside the dry belt, forests

can be grown and extended with ease and rapidity if the simplest laws of nature are observed. And there is land enough in the United States suitable in every respect for forest growth, but utterly unfit for agricultural use, to supply with forest products any possible population this country can contain.

But in spite of these natural advantages, in spite of the variety and value of our forests, all thoughtful persons familiar with their present condition and the dangers which threaten them under existing social conditions, must be filled with apprehension at the almost inevitable destruction of their productive capacity.

Americans are still surprisingly ignorant in regard to their forests and the simplest laws which should govern their management. This indifference is astonishing. We cut recklessly and often needlessly; and often fail to cut when cutting is essential. Fires are allowed to run unchecked year after year through the forest or to sweep over land upon which new forests would naturally appear. Cattle and other domestic animals range at will through the woods, injuring trees and exterminating seedlings. Our civilization and our foresight as shown in the care of our forests, is the civilization and the thrift of France two centuries ago. In no other civilized nation of the world are forests so recklessly managed.

Americans are impatient of any restraint or interference in the management of their property. And yet unless American land-owners, like the land-owners of nearly every other civilized people—Great Britain now being the only important exception—are willing to submit to laws, regulating under proper official control the cutting of their forests and the use of their land for agriculture or forest, according to its quality, we must not expect to keep up our forest supplies. These supplies are still enormous, but no forests, whatever their extent or richness, are inexhaustible. As one of the wisest observers of all social problems and one familiar, too, with the requirements of the forest has pointed out in another column of this issue, the condition of public sentiment required to make a proper management of our forests possible, will develop slowly. Americans as a nation need instruction in the laws which govern forest growth and forest management. This lesson they will not learn readily or quickly, and it is probable that they will not learn it thoroughly until compelled to by dire necessity.

Hardy Rhododendrons.

THE cultivation of hardy Rhododendrons, especially varieties of the race which English gardeners have produced by crossing the American *Rhododendron Catawbiense* with different Himalayan species with highly colored flowers, like *R. arboreum*, has greatly increased in this country of late years. Many Americans, probably, first learned the beauty and value of these plants for ornamental gardening at the Centennial Exhibition in Philadelphia, where an English nurseryman displayed under canvas a large and well arranged collection of the best varieties. That we know so much about these plants here, and have learned which can and which cannot be successfully grown in the United States, is very largely due, however, to the experiments in Rhododendron culture long carried on by Mr. Hunniwell in his beautiful gardens at Wellesley, in Massachusetts.

The cultivation of these Rhododendrons is very simple. They thrive best in deep peaty soil, and when placed so as to escape the stimulating influence of the warm sun of early spring. Impatient of drought, Rhododendrons in this country give the best results when planted in situations which never become thoroughly dry in summer, like the borders of ponds or swamps, or in which they can be freely and frequently watered; and in order that they may bloom well they should not be placed under the immediate shade of overhanging trees. No plants are

more easily transplanted. The cultivation of Rhododendrons, however, must always be restricted in the United States to a comparatively small area. A limestone soil is fatal to them. All attempts to introduce them west of the Hudson River have failed, therefore, and even along its eastern bank they have never grown satisfactorily. North of Massachusetts the winters are too cold, while south of Pennsylvania they cannot support the hot, dry summers of the seaboard region. They will probably succeed anywhere in Pennsylvania east of the mountains; but some day it will be found that they can be more successfully grown in the mountains of Virginia and the Carolinas, where summer droughts and excessive cold are unknown, than in other parts of the country. Here is the true home in America of broad leaved evergreens, and here sooner or later will be seen a garden of these hybrid Rhododendrons, only surpassed in splendor by that natural garden where the native Rhododendrons spread in countless thousands over the upper slopes of the noble Roan Mountain.

The question is often asked, Which varieties of these hybrids are hardy? The following list embraces the best of those which have for many years proved perfectly hardy in the climate of eastern New England: *Everestianum*—with rosy lilac flowers—one of the oldest and freest blooming of the whole race, unequaled in habit and beauty of foliage; *Lady Armstrong*, pale rose; *Charles Dickens*, dark scarlet; *Album elegans* and *Album grandiflorum*, pale blush; *Charles Bagley*, bright red; *Delicatissimum*, later in flowering than many of the others—the flowers blush, tinged with pink towards the margin of the petals; *King of the Purples*, a free blooming variety of good habit, with rather dark purple flowers; *H. W. Sargent*, a very late bloomer with large trusses of crimson flowers, but rather defective in habit; *Roseum elegans*, an old and long tried variety of excellent habit; *Purpureum grandiflorum*; *Mrs. Milner*, crimson; *Alexander Dancer*, the flowers fine and large, rose, with a light centre, but the habit of the plant not good; *Hannibal*, a late blooming variety with rose-colored flowers.

There are other varieties no doubt which are hardy in Pennsylvania, or on Long Island where a great deal of attention has been given to the cultivation of these plants.

— — —

Sir Joseph Hooker, of all his contemporaries, can speak with the greatest authority of the position of Asa Gray, in the hierarchy of botanists. The friendship of these two men, the one English the other American, extended over a period of fifty years. The sympathy which existed between them was never broken, and to no one else did the American botanist write so constantly or so freely. The following extract, therefore, from a sketch of our associate's life, by his English friend, printed in a recent number of *Nature*, is of peculiar interest:

"When the history of the progress of botany during the nineteenth century shall be written, two names will hold high positions—those of Professor Augustin Pyrame De Candolle and of Professor Asa Gray. In many respects the careers of these men were very similar, though they were neither fellow-countrymen nor were they contemporaries, for the one sank to his rest in the Old World as the other rose to eminence in the New. They were great teachers in great schools, prolific writers, and authors of the best elementary works on botany of their day. Each devoted half a century of unremitting labors to the investigation and description of the plants of continental areas, and they founded herbaria and libraries, each in his own country, which have become permanent and quasi-national institutions. Nor were they unlike in personal qualities, for they were social and genial men, as active in aiding others as they were indefatigable in their own researches; and both were admirable correspondents. Lastly, there is much in their lives and works that recalls the career of Linnæus, of whom they were worthy disciples, in the comprehensiveness of their labors, the excellence of their methods, their judicious conception of the limits of genera and species, the terseness and accuracy of their descriptions, and the clearness of their scientific language."

Laws Alone Cannot Save Our Forests.

THE greatest obstacle in the way of a rational and practical treatment of the subjects and interests connected with Forestry in this country is the lack of thought among our people. There are reasons for this want of thought, and it is well to understand the facts of the existing condition of things. Most Americans are busy in making a living, and their energies are entirely applied and absorbed in business pursuits, so that they have no force or energy which remains unemployed, or which can be spared from the occupations which already engage their powers. There are many other persons who have not been taught or trained to think on any subject. They have no ability to represent to themselves, by the picture-making power of the imagination, any subject which has the least complexity, or any scheme of facts and of their relations to each other. They cannot consider such a subject, cannot compare or classify facts, or draw inferences from them. This want of the power of thought is one of the chief hindrances to our advancement in civilization.

The only constituency to which we can at first directly appeal in the effort for an intelligent treatment of Forestry subjects, is the class of men and women who have some power of thought, and whose personal force is not already wholly employed in affairs. They have some ability to direct their faculties to new topics, and have enough public spirit, or regard for the general welfare, to incline them to give attention to whatever can be shown to have vital relations to the interests of the community or of the nation. In order to reach this class of persons there must be a clear, vital, coherent, systematic and continuous presentation of the facts and essential relations of the subject in hand, with such variety of illustration, application and recurrence to the original central object and purpose as shall produce in the minds of readers a vivid and abiding impression and conviction of the true nature and importance of the doctrines which are to be inculcated, and of the practical objects which such teaching is intended to promote or secure. A vital, intelligent, comprehensive and iterant treatment of the subject of Forestry, and of the interests connected with it, is greatly needed.

Such treatment as this topic has hitherto received in this country has been mostly fragmentary, incoherent and vague. As it is usually handled the whole matter is too much "in the air." There is a good deal of hammering upon the importance of the general subject, without sufficient observation and comparison of concrete facts and conditions here in America. The study of European methods and results in Forestry by competent men is, of course, highly valuable, but it is not enough. It is not even the most important thing for us. Nothing can be very useful to us which is not based upon careful study of the facts and conditions which are peculiar to this country. We should have in time a system of American Forestry—we must have it, indeed, if we are to avoid serious disasters to our national interests and civilization. We cannot import and adopt ready-made European systems or methods. The Forestry of this country must be the product of growth which has, as yet, scarcely begun. It will be developed by continued and widespread observation, and by constant comparison of the results of practice. It is necessary to remind ourselves that no useful system of Forest management can be originated or created by legislative enactment. There must be considerable special knowledge, and considerable national good sense regarding the needs of this country, behind Forestry laws, or they will be not only useless but mischievous.

The work required to effect any considerable actual advance in Forestry in this country must be long and difficult. Such objects can be attained only by the development of such intelligence, thought and sentiment, in a considerable proportion of our population, as shall secure a sensible and practical treatment, in individual and collective action, of the whole matter of the relations of Forests and Trees to

human life and welfare. Whatever tends to a better understanding or appreciation of the value of Trees in their economic, sanitary or æsthetic uses and influences, will help toward the attainment of these objects.

J. B. Harrison.

Landscape Gardening.—III.

THE landscape gardener, we have seen, has a great advantage over other artists in that Nature is his helper as well as his teacher. His work is the same in substance as her own, which means that it includes in equal measure the charms of color and of form, of atmosphere and of light. It is alive, and so there lie within it possibilities of infinite variation with their sequence of ever new delights for eye and mind. And it may be as perfect in execution as in general effect, for Nature will give all those finishing touches which are impossible to the hand of man.

But does not this partnership with Nature deprive the artist of that most essential of all opportunities—the chance for self-expression? Art, after all, is not imitation but creation; and creation implies the exercise of the individual will, the revelation of the personal thought. Sometimes the artist begins within himself, sets his own ideal and finds his own conception, taking from Nature only his brute materials. The architect takes stones from her and the musician takes sounds; but she suggests no houses or cathedrals, no symphonies or chorals—scarcely so much as a shelter for the human body, scarcely more than hints of melodies and harmonies. At other times nature furnishes ideals and patterns but not the methods by which they must be transmuted into different materials. She shows us what the beauty of woman ought to be, but we must find out for ourselves how to paint it on flat canvas, how to reproduce its vitality and charm in colorless marble. Not in the one case more than in the other—not in the arts of representation more than in those of construction—can the artist copy. He must always interpret. To interpret means that he must invent; to invent means that he must use his mind; and, in truth, it is simply in using his mind that he gets the chance to be an artist. The less the beauty of his work depends upon mere imitative efforts, the more it depends upon qualities for which he is himself responsible—upon expression—the higher may be its rank as a work of art; and the more personal is the quality of its expression—the more unlike it is to the expression which other men have put into their works—the higher is his rank as an artist. Now it will be the expression of emotion, told through human forms and faces in moods of supreme intensity, moral, intellectual or physical. Now it will be the expression of a feeling for certain peculiar moods and effects of inanimate nature, or of a delight in some particular combination of colors or some especial kind of form; and again, the expression of a craftsman's pleasure in the mere problem: How can this richness of brocade, this sheen of marble, this softness of hair or cheek, be most perfectly translated into paint? It matters not what a man shows us as having been present in his heart while his brush was at work;—so long as he shows us something that was there, he is an artist. If he could make a literal, impersonal copy from nature it would not be worth the form it imitates. The only value it could have would be historical, not artistic—would be a permanent record of the perishable model. To make his work worth while as art, the artist must even the balance by putting himself into the scale.

If the landscape gardener were indeed denied the chance to do this he would merely be a more or less skillful artisan. But he is not denied it. In fact he cannot escape if he would from the necessity to use or abuse his opportunities for self-expression. It is no truer to say of him than of the painter or the sculptor that he copies nature. Though they simply work after her and he works in and with her, his aim is the same as theirs—to re-unite her

scattered excellences. Theoretically he could copy her in a very wide sense of the word; but practically he can copy little more than her minor details and her exquisite finish of execution. Composition of one sort or another is the chief thing in art, and the landscape gardener's compositions are and must be his own. Through them he may express his own ideals, and through them he may reveal himself either as having or as not having clear ideals, either as knowing or as not knowing how they may be realized. If he is Nature's pupil he is also her master. "Nature," writes Aristotle, "has the will but not the power to realize perfection." Turn the phrase the other way and it is just as true: "She has the power but not the will." In either reading it means that the man can aid and supplement Nature's work. He can bend her will in many ways to his though he must have learned from her how to do it. He cannot achieve anything to which her power is unequal, but he can liberate, assist and direct that power. He could even remove her mountains if the result were worth the effort; and he can blot them out of his landscape by the simplest of devices—by a clump of trees and shrubs which she will grow for him as cheerfully as though they were to hide some deformity of his own creation. He cannot make great rivers; but he can make lakes from rivulets and cause water to dominate in a view where she had meant green grass to rule. And he can even teach her to perfect details of decoration for whose beauty scarcely a hint is found in her unassisted work. All "florist's roses," for example, are not productions to be proud of; but there are some in which, sterile though they be, Nature herself may grudge man's skill its part.

M. G. van Rensselaer.

The Suburbs in March.

IN the suburban districts of our Northern cities this is the most dreary season of the year. The snow is gone or remains only in patches, the grass is dead and colorless, the houses in their forsaken inclosures seem to shiver—all is dishevelment and nakedness for a whole month at least. In the close-built city there is no such unhappy state of things. In the open country even March has its beauty. What is the cause of the repulsiveness of the half-way region at this season and what is the remedy?

Plainly we cannot throw the blame upon the severity or fickleness of our Northern climate, for how then could the country-side have any beauty about it at this time? The cause lies rather with ourselves, who have built streets and houses through the fields and woodlands, have in this way destroyed the original beauty of the land, and have as yet done little or nothing to win back what we may of it. In these fields and pastures grew a great variety of trees, shrubs and herbs, many of which attained their perfection only in summer, while others were especially striking in winter. Of the former our public and private grounds hold far too few—our sins of omission are surprising—but of the latter almost none. Where can be seen planted about homes the richly-colored Red Cedar, or prostrate Juniper, or Mountain Laurel, or Bayberry with its clustered gray fruits, or red-twigged Wild Roses, or yet redder Cornels, or golden-barked Willows? How seldom appear White Birches or any of the American Firs and Spruces! Where do any of the trailing evergreens cover the ground at the edges of shrubberies? Where are the houses which have bushes crowded about their bays and corners, as the wild bushes crowd the field walls, till they seem to be fairly grown to the ground? Where is any suggestion of those thickets of mingled twigs and evergreen which so adorn the pastures even in March? Speaking generally, we have reduced our bits of ground to mere planes of shaven grass, from which the house walls rise stiff and unclothed. We expend thousands of dollars upon the shell of our abode, and indefinite sums upon its interior appointments and decorations; but outside we generally leave it all bare and unbeautiful, and spend only for the gaudy brightness of Geraniums in summer. No wonder March is ugly in the suburbs!

The remedy, then, is the planting of appropriate and numerous shrubs and small trees. Beware of the "choice specimens," many of which will need to be protected by boards or straw during five months of the year, and avoid the common mistake of clothing the ground with single plants. This, at

any rate, is not the way to make March door-yards less bleak. Rather may we spend the same money in planting mixed and somewhat crowded thickets, here of high and there of dwarf bushes, along the fences and close about the house. To clothe the nakedness of the ground and of the fences and buildings should be our aim. Large trees, such as our suburbs are sometimes full of, cannot do this, neither can scattered specimens of smaller sorts, neither can sparse, stalky shrubberies; we must set our bushes thickly, so as to hide the dirt beneath them, and we must either carry the grass under them as far as possible or else cover the bare earth with trailing plants. This done, our yards and grounds will appear well furnished and sheltered, and no coming March will ever chill us as this present month has done. Moreover, when summer comes, we shall find we have exchanged our Geraniums for banks of foliage set with a succession of flowers which are much more interesting and will bloom season after season. Where house-lots are small and it is desired to spend a comparatively small amount on each, the neighbors could form clubs and secure plants at wholesale rates; but under any circumstances the cost of such planting is by no means so great as to excuse us from attempting it.

Boston, March, 1888.

Charles Eliot.

California Christmas Flora.

AFTER twenty successive winters on the northern shore of Monterey Bay, Cal., I may claim the privilege of saying something about our Christmas flora.

The winter season of this region is not so clearly defined as in more northern latitudes. The leaves of our deciduous trees forget to loosen and fall, and almost imagine themselves evergreen. And indeed some of them have carried their imaginings so far as to retain, oftentimes, the old leaves until the new ones are fully grown.

At Christmas time, however, Nature has called a halt. Some of the spring buds that were caught in the dry season, which begins about the middle of June, have expanded with our fall showers and have bloomed regardless of the season, so that at the close of the year there is often a profusion of many kinds of flowers—wild as well as cultivated. They are the arrears of the past season, and not the beginning of the coming year.

Some years ago the editor of a horticultural journal requested me to make a list of wild flowers in bloom on January 1st. I found about forty species. Since that time I have noticed that a majority of our native plants are liable to bloom at that season; first, from delayed buds on account of the dry season, and second, from premature spring buds forced out by the warm early rains and the mildness of the season. This is frequently noticed in Pear and Apple trees—they being strangers to our climate, seem to lose their reckoning and send forth flowers out of the proper season—although such a phenomenon occurs at times in more northern regions and away from the sea coast.

So many, then, of our plants, both native and introduced, may be found blooming at Christmas-time, that a list would be very long. In fact, there are but few which might not be found in bloom in favorable years and localities.

Consequently we have at Christmas, and later, Strawberries, Raspberries and sometimes other small berries. Grapes grow and ripen until that time; Tomatoes likewise. Most of the table-vegetables are young and tender even throughout the entire winter. Some tropical trees, and those brought from south of the equator, take on an active growth. And even early in January some of our indigenous plants send forth their flowers, especially those in warm, sheltered places, such as the Willows, Alders and Hazel. One Willow (*Salix flavescens*) is quite a surprise in January, when the trees, bearing staminate flowers, are usually out in full glow, like beautiful yellowish-white clouds, on the brushy mountain sides. A Lily (*Scoliopus Bigelovii*) to be found in bloom must be sought in January; and many times have I wondered where and when the flower might be found, until I discovered it thus early in the season and before its beautifully spotted leaves were fairly expanded.

The growth of our marine flora is similar to that of our land plants at Christmas-time. If storms have not raged severely we find many nice specimens of young plants in vigorous life and maturing fruit. And the "moss-gatherer" is often well repaid by the collections made at this season. The temperature of the sea is not much below that of summer; and but for the storms, vegetable life in our bay would continue almost uninterruptedly all the year.

A little further along and the accounts for the past year

are all balanced, and new leaves are opened for the new year. This change takes place at February 1st. That is our true beginning of spring. As the days grow longer the heat of the sun is stored in the fields and mountain sides, to be radiated during the clear nights, and the growth of vegetation advances slowly but surely to its culmination in May and June. The opening of spring flowers, however, is not as rapid as in the Northern States. With our cool nights and not very warm days, they come forth coyly, until quite sure that the earth has passed the tossings of Taurus and the stings of Scorpio. Then in May the lingering, bashful, yet beautiful flowers that slept over the Christmas-time, gladden the hearts of all lovers of these, the most lovely of Nature's gifts.

Santa Cruz, Cal.

C. L. Anderson, M.D.

Foreign Correspondence.

London Letter.

Our flower markets make just now a beautiful display with forced flowering bulbs especially. Every market-garden around London is a flower show in itself. I went through one of the largest yesterday. I was astonished at the brilliant scene. One house a hundred yards long was filled with nothing but Tulips, mostly single sorts, the favorites being scarlet, yellow-edged, Duc Van Thol, also the white, rose and yellow Van Thol. These make up the bulk, and of double sorts which are not popular in the market, the leading varieties in this nursery were the Tournesols, scarlet and yellow. To give some idea of the Tulip trade alone I may mention that one grower forces nearly 200,000 bulbs. They are packed in shallow boxes as closely as they can be laid and covered with light soil. When the buds are ready to burst the bulbs are either potted four or five together, with ferns, or the flowers are cut and sent to market. Another house was filled with Lilies-of-the-Valley also in flat boxes, the finest German crowns being preferred to English, as they throw longer spikes. The best strain of the flower in the market is the Victoria, which is controlled by a grower in the Thames Valley, where this particular sort grows to a great size. The spike is longer, the bells larger and the foliage more robust than in the common kind. Throughout the winter till Lilies-of-the-Valley flower outside, a lucrative trade is done in London with these flowers, which are *par excellence* the favorite for button-hole bouquets. In this same nursery I remarked the great abundance of the old white Azalea, represented by old plants that had done duty for years and had been hacked every year to the bare stem. Of course the plants were unsightly, but they were part of the working capital of the concern and yielded abundant and profitable blooms.

Your famous *Lilium Harrisii*, or, as it is commonly called here, the Bermuda Lily or Easter Lily, is becoming very popular among the market people. They cannot, however, get enough of it at their price. A ship load of bulbs could easily find sale about our London market-gardens. I saw a grower the other day who makes a specialty of *L. longiflorum*, of which *L. Harrisii* is, of course, only a more floriferous and dwarfer variety, and of *Calla Ethiopica* (Nile Lily we call it), expressly for Covent Garden market on Easter eve, April 1st. He grows thousands of each and this represents much capital. His aim is to get them in flower on March 31st to the day. He does not want to be made an April-fool, so he has to watch the barometer. Last week was Italian weather—sunny and warm—and he had to put the temperature down; this week is Labrador weather, with frost and snow; he must put it up again or his blooms will not open when wanted. His struggles with our climate are rather comical to the looker-on, but the matter is a serious one to him from a business point of view.

The Orchid men are just now sharply watching their flowers, especially those on imported plants that have not yet bloomed in this country. They anxiously await the opening of every spike, for often a plant bought for a crown at auction, by a peculiar arrangement of its flower spots or a deepening of its color beyond the ordinary, will bring £50. Some time ago it was said that Orchids were declining in popular favor, but the contrary is the case. New buyers may be seen at the auctions, men who never grew any plant in their green-houses rarer than a Scarlet Pelargonium, and they are turning out everything to give place to the popular favorites. This explains how such enormous Orchid establishments as those of Veitch, Sander, Bull, and Williams are kept going. But not only are the growers paying increased attention to Orchids, but botanists are influenced by the fashion (I was going to say craze). At Kew one of the assistants at the Royal Herbarium has been detailed specially for the work, which, however, is

FROM A BRONZE MEDALLION BY A. ST. GARDENS

— "LAND AND FOREST SUPPLEMENT" MARCH 12TH

chiefly that of correcting and checking the nomenclature, and tripping up the veteran German professor, Dr. Reichenbach, who for a generation past has held the monopoly of naming Orchids. One of our Orchid specialists attached to the St. Albans establishment has been taking notes in the Orchid collections about New York and has printed them in the *Gardener's Chronicle*, the result being that our growers here do not now think that Americans are such infants in Orchid culture as was fancied. Some of your collections there described would, I imagine, take equal rank with the best in England.

The Royal Horticultural Society held its periodical meeting of committees on the 14th inst. This will be nearly the last it will hold in the aristocratic quarter of South Kensington. The annual meeting held on that day decided that the society should vacate South Kensington as too costly to maintain, and a more modest home has been found for its offices, library, etc., further eastward. A stranger who could have seen the last meeting would hardly have thought the society in a moribund condition. The crowds of horticulturists constituting the committees, the profusion of flowers, choice and ordinary, and the plentiful collection of late apples, all tended to show how active horticulture is in this great centre, and that it is not for lack of interest or sympathy that the national society is not the largest and most influential in Europe.

The advent of spring was indicated on this occasion by the large gathering of spring flowers—Chinese Primulas, Cinerarias, Cyclamens, Camellias, forced Narcissus, and, of course, Orchids. The Orchids new and rare, choice and common, were plentiful. One of the most remarkable was a new hybrid *Dendrobium* (*D. Chrysodiscus*), a cross between another hybrid, *D. Ainsworthii* and *D. Findleyanum*. The distinct features of each parent are plainly seen in the progeny, especially in the large jointed stems, and the shape of the flower, which is as large as those of *D. Findleyanum*, with sepals and petals white, tipped with rose, and the shallow lip adorned with a broad blotch of yellow and ruddy crimson. Another *Dendrobium* certificated is considered among the most remarkable of new orchids. It is called *D. nobile Cooksoni*, being a variety of that old species. The flowers are like those of the type in size and form, except that the two lateral or side petals are shaped and colored like the lip, each having a heavy blotch of the richest maroon-crimson bordered with white. It represents what botanists call an instance of "trilabella," or thrice-lipped flowers. In other respects it does not differ from our old favorite.

A certificate was well bestowed upon an extraordinarily fine *Lycaste Skinneri*, named *Imperator*, from Sander of St. Albans. The flower is very large, the sepals broad and thick, faintly tinted with pink, the petals of a glowing crimson, and the lip of an intensely deep ruby-crimson, variegated with pure white. In contrast with this, the same exhibitor showed an exceptionally fine form of the white *Lycaste Skinneri*.

London, Feb. 25th.

Wm. Goldring.

Palms for House Decoration.

THE species belonging to the natural order *Palma* constitute a truly royal class of plants, justly entitled to Linnæus' designation, "Princes of the Vegetable Kingdom." They comprise various types of beauty; some of the stronger growing kinds (as *Latania Borbonica*) being of bold and striking outlines, the embodiment of sturdy grace; others having the lightness and elegance of the finer varieties of Ferns, as *Cocos Weddelliana*, *Geonoma gracilis*, and the like. The latter varieties are of miniature growth, and from their graceful and delicate forms are specially useful for table decoration, and form objects of the greatest beauty when standing alone on pedestals or small tables. The stronger growing and taller kinds may be used to advantage standing on the floors of rooms and in the hallways, or grouped in front of mirrors or windows. The increasing use of Palms and other pot plants for decorative purposes in this country is an evidence of the growing taste of our people. Beauty of form is of a higher type than beauty of color, and the graceful outlines of a tastefully arranged group of Palms give a higher satisfaction than the immense banks of cut flowers we sometimes see. Cut flowers, used with judgment, are always welcome, but they should not be crushed together, so that the individual forms are lost, and the only effect is a mass of color. There are now over eleven hundred recorded species of Palms. I shall name only a few of those best adapted for house decoration.

Latania Borbonica, a Fan Palm, is more largely used than any other, as it grows easily and is a plant of dignified expression. *Areca lutescens* is one of the most graceful, tall growing species,

with bright, glossy green foliage and rich golden yellow stems; it is now grown in very large quantities. *Areca Verschaffeltii* is not so often seen as the last named, but it is very distinct and showy, with dark, shining green foliage with a dark band through the centre of each leaf.

Kentia Canterburyana, the Umbrella Palm, in its native country attains a height of thirty-five feet, but is slow of growth under cultivation in green-houses, requiring seven or eight years to reach a height of five feet. It is valuable as a house plant on account of its tough and enduring qualities. There are several varieties, of which *K. australis* and *K. Fosteriana* are the best known. All are handsome, and capable of sustaining, without injury, as much neglect as any Palm in cultivation. *Phoenix rupicola* is a plant of exquisite grace, the finest of its genus. *Phoenix sylvestris*, the Wild Date, is of coarser growth than *P. rupicola*, but valuable for its distinct character and enduring qualities. *Raphis flabelliformis* is a plant of erect growth, having the stems covered with coarse fibre; a grand Palm for house culture, enduring either heat or cold and much neglect without injury. It is very distinct and handsome. *Raphis humilis* resembles the last, but is more delicately graced; one of the very finest Palms in cultivation.

Ptycosperma Alexandra, the Australian Feather Palm, is a quick, robust grower, inexpensive and useful. Although a native of the tropics, it will grow well in a temperature as low as 50°. *Seaforthia elegans* somewhat resembles this species; it is tall and graceful. Plants ten feet high and upwards are most effective, as they do not show to the best advantage when smaller. *Cocos Weddelliana* is the most elegant of the smaller Palms, with finely divided foliage, recurved with exquisite grace. Small plants are unexcelled for dinner table decoration. *Geonoma gracilis* is very similar to *C. Weddelliana*, with somewhat coarser foliage, but of the same graceful habit. It should not be grown in the house for more than a few days, as it requires an atmosphere more moist than can be given it outside of the hot-house. *Prichardia grandis* is dwarf and of slow growth, a native of the South Sea Islands, with leaves about two feet long and three feet broad. It is rare and beautiful. *Maximilliana regia* is not very plentiful yet, but is destined to grow in favor, being quite distinct and striking in appearance. It is of easy culture and one of the hardiest and thriftest Palms under neglect. *Oreodoxia regia*, the Royal Palm, is a native of the West Indies and tropical America and a prime favorite. Tall, slender and stately, it is most effective when used in a group of lower growing species.

All the above, except *Phoenix rupicola*, *Seaforthia elegans*, *Cocos Weddelliana*, *Geonoma gracilis*, *Prichardia grandis* and *Oreodoxia regia* may be successfully grown in the house all winter if the following rules are observed: Pot them firmly in soil composed of equal parts of loam, sand and fibrous peat, with a small proportion (say, one-twentieth part of the whole mass) of charcoal. Use pots as small as possible; nothing injures Palms more than over-potting. Drain well and water freely as often as the soil gets dry. Palms are often injured by insufficient watering. The surface may be kept wet while the lower roots suffer from drought. The leaves should be thoroughly sponged with water of the temperature of 60° or 70° twice a week, and to keep away insects the water, every two or three weeks, should contain Fir tree oil in the proportion of half a gill to two quarts of water. This is, without doubt, the best insecticide at present known for keeping Palms clean and healthy.

Robt. Craig.

Philadelphia.

"In the park I make it a point to use only native or thoroughly acclimated trees and shrubs, and avoid entirely all foreign decorative plants. For nature beautified must still preserve the character of the country and climate in which the park is situated, so that its beauty may seem to have grown spontaneously, and without betraying the pains which have been spent upon it. We have growing wild in Germany an abundance of blooming shrubs, which can be used in a variety of ways, but if we find a Damask Rose or a Chinese Lilac, or a group of such things, planted in the midst of wildness, the result is a painful feeling of incongruity; unless, indeed, they be set apart and fenced off, as for instance in a hedged garden near a cottage."—Pukler-Muskau, 1834.

"The simple and uncombined landscape—if wrought out with due attention to the ideal beauty of the features it includes—will always be most beautiful in its appeal to the heart."

John Ruskin.

A View in Central Park.

THE view on this page is taken from a point in the Ramble in the Central Park of this city, looking southward, and including a portion of the Terrace. Of course, it is much more than a picture of the Terrace, but it clearly shows how much this bit of architecture adds to the composition. The distant horizon line of trees has an attractiveness of its own. Nearer by are the upper Terrace lines contrasting with the masses of foliage above them. Below these are the open arches with deeper shadows, then the lower lines of the Terrace, the lake shore and the passage of water separating more distinctly the extreme distance from the middle distance. All these, with the lines of the shrubbery about the little lawn, mark the successive planes of the composition and help to bring out the gradations of light and shadow. In the Park the observer would enjoy in addition the ever varying tints of the sky which would also be reflected in the water, while he could look up to and into the leafy framework in the foreground forever without exhausting its interest. The illustration is a good ex-

Plant Notes.

Lilium Parryi, and its Habitat.—This fine Lily appears to have won its way in the ten years of its garden career to a high rank among cultivated species. The pure lemon yellow of its flowers, an unusual shade among Lilies, and their peculiar form, as well as their fragrance, combine to make it a unique species. Its range is from the springy banks and swampy cañons of the San Bernardino Mountains of southern California, where Dr. Parry discovered it in 1876 southward towards Lower California, eastward to the higher mountains of southern Arizona and thence southward, I am confident, along the western slopes of the Sierra Madre of Sonora. In these arid regions it is only by mountain brooks and springs that it can find the water its roots require, and shelter from scalding sunshine. So its habitat is the narrow sandy or peaty alluviums of these brooks, or their mossy margins, or even the ledges, over which they glide, where its bulbs are scarcely hidden from view amidst tufts of moss. Seeing it always in such wet situations I gained the impression

A View in Central Park.

ample of what can be accomplished by framing in a distant object with foliage, so as to make a complete and consistent picture, and there is no reason why such planting as it shows should be confined to public parks. Many a lawn could be made the foreground of a picture quite as attractive, and it could be graded and planted so as to emphasize the interest and increase the pictorial effect of some important object, natural or artificial, and trees could be disposed about it so as to concentrate the attention which would otherwise be distracted by surrounding objects.

“One beautiful way in which flowers can be used, especially those distinguished for the brightness and clearness of their coloring or for their tall stalks, is to plant them in moss and among wild vegetation along the edge of a brook or some other piece of water. The reflections in the water and the play of their movements thus doubled clothes with a new charm this scene which is altogether natural.”—Hirschfeld's “*Theorie der Gartenkunst*,” Leipzig, 1777.

that it would need wet soil. But northern brooks would be too cold, and with our frequent rains ordinary soil suffices for it, since I have flowered it from Dr. Parry's seed in my garden. In its native haunts, crowded upon by other plants, especially beset by grasses and shrubs, its stature is from one to three feet and the number of its flowers one to six. In cultivation I have seen these figures nearly doubled.

A New Morning Glory, *Ipomea Pringlei*, Gray, collected in 1886 on cool, grassy hillsides near Chihuahua, and distributed among my *Planta Mexicana* of that year, was admired by Dr. Asa Gray even in dried specimens, and by him recommended for cultivation. The species is perennial from a thick root, with an annual stem, erect, diffusely branched, two or three feet high and broad, with inconspicuous leaves and flowers of the largest for the genus, three inches broad, purplish blue, with a metallic lustre, and in their throat lighter blue or nearly white. The plant is common over the hills and high plains between Chihuahua and the Sierra Madre. As seen by the traveler in those lone regions, profusely covered with bloom throughout the morning, it is a bright and pleasing object.

C. G. Pringle.

Some Hardy Wild Flowers.—One cold day in February I went to see how my plants of that tough little Orchid, *Goodyera pubescens*, were standing the weather, and found the leaves protruding from a crust of snow and ice, as fresh as in June. One can hardly understand how such a velvety, delicate looking plant can be so hardy. Although it grows in thick shade, this Rattlesnake Plantain will thrive in a sunny window of a warm winter room. Such a one I knew, and when the fire went out one bitter night it was smiling freshly in the morning, although every other plant in the collection had perished. Why has such a pretty thing as *Erigeron bellidifolium* been neglected by cultivators? I accidentally discovered that it improves under domestication. A bunch of it was left by chance in a field, where it was hoed and fertilized in the same way as

perhaps, where Michaux makes record of it in his journal of that trying December visit to these mountains. I can hardly hope much from the pretty little *Galax aphylla*, known here as Colt's-foot, and carpeting the woods in every direction. It seems to resent all artificial nurture and apparently dies of homesickness when transplanted from its wild surroundings.

Macon Co., N. C.

F. E. Boynton.

Phajus tuberculosus.—This exquisite and rare Orchid is now in flower at Kenwood, probably for the first time in America. It is undoubtedly the most beautiful of the whole genus. It was introduced from Madagascar in 1881, and a few plants flowered in England, but for a long time I have heard nothing of it. Our plants were bought in 1882, and were gradually dwindling away

until a year ago, when we thought of trying them in the hottest corner of the Phalænopsis house near the expansion tank, where the temperature in winter is never below 70°. We kept them very wet, and syringed overhead at least twice a day. Under this treatment the plants have done wonders, making larger bulbs than those imported, and the strong healthy foliage shows no speck of ravages from insects, hitherto the greatest enemy of this plant. The choice of potting material seems to be a minor consideration, as one of the plants in bloom is potted in peat, while another is on a block of wood covered with sphagnum and stands upright in a pot surfaced with moss; in both cases the rooting is all that can be desired. The habit of the plant is somewhat climbing, producing a slender rhizome, much thickened at the end to form a bulb, from the tip and sides of which proceed plicate leaves about a foot long. The flower spikes are upright, 6 to 8 inches long, bearing 3 to 6 snow-white flowers, the greatest attraction of which lies in the indescribably beautiful lip.

Kenwood, N. Y.

F. Goldring.

Fig. 6.—*Aquilegia longissima*.

the farm crop. It grew luxuriantly and blossomed profusely. I think it quite as beautiful as any of our Asters, which it somewhat resembles. It has the advantage, too, of blossoming in early spring, while most of the Asters are late bloomers. Another wild plant which is not afraid of cultivation is *Houstonia purpurea*. While not as attractive as its little sister, *H. serpyllifolia*, or, perhaps, as your more northern Bluets (*H. cœrulea*) it is a striking plant, erect, branching and often more than a foot high, blossoming freely, and found naturally in high and dry soil. Our Mountain Harebell, too (*Campanula divaricata*) makes a neat addition to our list of hardy perennials. I think I may add *Shortia* to the list, although it has not been thoroughly tested in cultivation. I have little doubt, however, that it will succeed, and it can now be had in abundance, after hiding away so successfully for a hundred years, for it has been found growing by the acre on the very spot,

a curious appearance. The unripe fruit is eaten boiled as a vegetable. This plant has given rise to many varieties, differing quite largely.

E. Lewis Sturtevant.

Aquilegia longissima.*

OF the long-spurred Columbines which are peculiar to the central mountain ranges of this continent the species here figured, fig. 6, page 31, is the most remarkable. The *Aquilegia cœrulea*, with blue and white flowers, and the yellow-flowered *A. chrysantha* of the Rocky Mountains and other interior ranges, are now well-known in gardens, both in their

**A. LONGISSIMA*, Gray in herb.; Watson, *Proc. Am. Acad.* xvii. 317. Tall, somewhat pubescent with silky hairs; leaves green above, glaucous beneath; sepals lanceolate, broadly spreading, an inch long or more, the spatulate petals a little shorter; spur with a narrow orifice, four inches long or more.

Fig. 7.—A Weeping Beech.

native forms and in the hybrids which are readily obtained from them. *A. longissima* is a still more southern species, found in the mountains bordering the Rio Grande in western Texas and those of the north-eastern provinces of Mexico. It is, indeed, probably the most southern species of the genus, inasmuch as the Guatemala habitat ascribed to *A. Skinneri* is very doubtful. *A. Skinneri* was cultivated in European gardens to some extent about forty years ago and was believed to have originated from seeds collected in Guatemala by Mr. G. U. Skinner. It has, however, been recently discovered at home in the mountains of Chihuahua, both by Dr. Edward Palmer and by Mr. C. G. Pringle, and the probabilities are that the seeds were sent from there, instead of from Guatemala, by Mr. John Potts who had charge of the Mint at Chihuahua in 1842. It is known that he and his brother made collections in that region and sent plants to England at about that time.

A. longissima is distinguished from the allied species not only by the greater length of the spur, but by its more contracted orifice and by the narrower petals. The flower opens upward, spreading widely, and is pale yellow or straw color, or sometimes nearly white or tinged with red. The plant has been raised from seed in the Cambridge Botanic Garden. It proves to be more tender than our common species, as was to be expected, but there should be no difficulty in cultivating it throughout the Southern States.

In view of the recognized adaptation of flowers and insects to each other for mutual benefit, it is an interesting question what long-tongued moths have developed side by side with this long-spurred flower, and how far the plant is really dependent upon such insects for fertilization. S. W.

A Weeping Beech.

The so-called weeping trees, or trees with distinctly pendulous branches, are not of the first importance in general landscape work. Their peculiarities of form are so striking that when planted with other trees they invite attention to themselves, instead of helping to increase the effectiveness of the group. A Weeping Willow on a wood border is the first thing to arrest the eye, and it seems to break the masses of foliage and belittle their effect instead of giving continuity and strength to their outlines. As individual specimens, however, these trees may become objects of great beauty and attractiveness. The Weeping Beech, a variety of the European Beech, is distinguished among them by an eccentric vigor which is seen in the sturdy upward and outward growth of some of the larger branches, a vigor which is in marked contrast with the pensile habit of the smaller branches. These trees vary greatly in form; some being tall and slender, others low and broad, and others still, assuming the most picturesque shapes. The tree in the illustration stands in the grounds of Mr. Samuel C. Jackson, in Flushing, Long Island, and in what was originally a part of the old Parsons nursery. It is forty-four years old, and its vigor is proved by its healthful appearance as well as by the dimensions it has already attained. It is about sixty feet high and the circumference of the circle where the hanging branches meet the ground is 180 feet. The trunk is 6 feet in circumference three feet from the ground, and a man standing by it is perfectly concealed from those without the circle by the thick curtain of foliage that hangs about him on every side.

Cultural Notes.

Chrysanthemums.—Those who would have good Chrysanthemums next fall must now pay attention to their stock. No puny plants will ever give good flowers, neither will plants which have been excessively propagated. Strong cuttings put in now and grown along without becoming pot-bound or starved, will make nearly as fine plants and flowers as those propagated earlier. Plants now in small pots should be removed into pots two sizes larger and subjected to fire-heat only sufficient to keep out the frost. Use at all times soil that will permit water to pass freely through it. All newly-potted plants, from the cutting benches, should be carefully shaded from the sun for a few days, until new root action is established. If it is the intention to grow very large flowers the plants should be topped as soon as they reach the height of from 6 to 8 inches, selecting the three strongest shoots to form the base of supply. If specimen plants are required, four shoots at least should be allowed to grow and each one should be tied down to a position nearly horizontal. These same shoots will require stopping again as soon as they have 6 to 8 leaves formed. If the soil is rich no additional fertilizer will be required until the summer is advanced. Purchasers would do well to obtain plants that have been grown cold and are not pot-bound. Plants should be shipped by express.

John Thorpe.

Asparagus plumosus.—Propagated by division, this plant is of less value to florists than Smilax. But propagated from cuttings, it makes bushy plants from six to twelve inches high, which are hardly equalled in beauty or usefulness for decoration. *A. plumosus* grown in this way is superior to *A. tenuissimus*, which resembles it very much, but is too thick. *A. plumosus nanus* must be propagated by seed, which is not easily obtainable. While every side shoot of *A. tenuissimus*, cut with a bit of the main shoot, will root easily, *A. plumosus* refuses to do so. It makes roots only when a bud starts into growth in soil or sand, and this is the whole secret. A young shoot first grows nearly to its full length before the side-shoots are developed, and those on the top develop first. Therefore, cut the whole shoot as soon as the upper side shoots and all those which have started about the same time with them have reached their full development—which is indicated by the darker green color—and lay the whole shoots about half an inch deep in sand in the propagating house, taking care not to bury any side shoots. After six or eight weeks most of the dormant eyes will grow and form one plant each. Let them stand undisturbed until three or four little shoots have made their appearance, when they should be potted in very sandy soil. When these plants are about six inches high they are excellent material for further propagation, and a large stock can easily be obtained in a short time, each shoot yielding from one to five young plants. *A. plumosus* and *A. plumosus nanus* are prettiest when young and before they change into their climbing habit. But the dwarf species seems to produce all its side shoots at the same time, the lower part of the stem remaining bare even with quite old plants. I succeeded once by cutting the end of a shoot away and laying the whole shoot in sand without separating it from the old plant, but the result was not entirely successful.

C. Briner.

Chamæcyparissus obtusa is one of the most beautiful and graceful of the Japanese Conifers. We have some old plants that had fallen into a dilapidated condition, and some years ago we cut them in hard and planted them by the side of a well enriched border in dry sandy land. They have recovered splendidly and now are vigorous, bushy specimens. Others in a similar condition were also cut in and removed to a well-sheltered spot in a thinly-planted piece of woodland, and where the ground is moist and good. The result has been fully as satisfactory as in the previous case.

Magnolias.—We had a group of choice Magnolias, including *M. Thurberi* and *M. stellata*, in dry sandy land, and where the subsoil was deep sand, but they appeared to be very unhappy. The surface soil in the bed was good enough; indeed, it was good hazel loam introduced for their benefit. A few years ago we removed the Magnolias, some to our nursery ground, where the land is deep, dark and moderately moist, and some to a sheltered place on the lawn, and in which the soil is excellent. In both cases their recovery is very marked. We also have large isolated specimens of the Yulan Magnolia, some in poor, some in good soil, and in vigor of plant and profusion of bloom the balance is greatly in favor of those growing in the good soil.

W. F.

Covering Bulbs.—If Crocuses, Snowdrops, Winter Aconites, Siberian Squills and other early flowering bulbs planted last fall were covered over with a mulching of tree leaves or rank litter in order to protect them from frost, they are now trying to thrust their whitened leaves and flowers up through the covering. If we remove the mulching we expose the weakened shoots to the piercing winds and in this way render worse what before was had enough. These bulbs need no winter mulching, neither do Tulips, Hyacinths, Crown Imperials nor the host of other early flowering bulbous plants we set out in our gardens, except it may be a mulching of rotted leaves or rotted manure, which is meant to remain on the ground permanently, and is applied more with the view of preventing the bulbs from being heaved out of the earth by frost than as a protection against frost. It is when these plants are appearing above ground that they need protection most, but the ordinary way of treating them, is to strip them just at this time.

Streptosolen Jamesonii.

THIS is one of the best and most easily cultivated winter-blooming green-house plants we have. It is a native of South America, and was introduced to cultivation some forty years ago but soon disappeared from our gardens and was not seen again till a few years ago, when it was reintroduced. It is now quite generally distributed.

It is a small-leaved, evergreen, slender shrub, or rather shrubby vine, of vigorous growth. Its flowers are orange or flame-colored, and disposed in drooping, terminal, cymose panicles; every branch is tipped with a bunch of flowers. Its flowering period is from January to April, according to conditions under which it is grown, but usually it is in its finest condition in February. A few scattering flowers may be produced all summer long, but never a full crop nor handsome panicles.

It ripens seed freely, but the best way of propagating it is from cuttings of the young wood; these cuttings strike as readily as do those of Heliotropes or other soft-wooded plants, and if struck in spring and grown on in summer make fine blooming plants 4 to 6 feet high by the next winter. I raise a fresh lot of plants in this way every year, and keep over some of the old plants till they are two or three years old, but not more, as they grow too big for our green-houses.

I grow them in pots during the summer months, and plunge them out-of-doors. Were they planted out the plants would grow so rank and root so much that they could not be lifted safely in autumn. They are gross feeders. In potting them I use good loam, with about one-fourth part in bulk of rotted manure, and after the plants are brought in-doors I mulch them with rich farm-yard manure.

We winter our plants in the Carnation-house, where they are grouped together in a mass. The right temperature is about 50°. They get and enjoy full sunlight.

Although gorgeous plants for conservatory decoration, the cut flowers must be used in masses to be effective. In warm rooms they do not last very well.

W. F.

[This fine plant, a native of New Grenada, was figured in the *Botanical Magazine*, t. 4605, many years ago as *Browallia*, a genus from which it chiefly differs in habit of growth. It is also figured by Miers, the founder of the genus *Streptosolen* (*Illustrations*, t. 55).—ED.]

Mulching Shrubbery Beds.

AS soon as the snow is all gone and the weather is not frosty we go into the woods, rake up and cart home a large quantity of tree leaves for mulching shrubbery, and more especially our Azalea bed. The leaves are then beginning to soften and decay, and if at all moist, we can pack at least twice as many into a load as we could in fall. Why was this not done last fall? For two reasons: Hardy trees and shrubs have no need whatever of any mulching over winter, and it may be so much work lost, but this is not all; for in the second place, it may be the cause of much mischief by affording a lodgment for field mice, which are the most destructive rodents we have to contend with. They are especially destructive to coniferous and rosaceous trees and shrubs by gnawing away the bark around the stem at the ground level; in this way they have killed many of our Pines and Spruces. But I have never known them to attack evergreen Rhododendrons, even where these shrubs have been heavily mulched with dry leaves over winter.

The earlier we mulch our Azaleas now, the better. If de-

layed much longer the flower buds will become so prominent that the least rub against them will break them off. Put on the leaves six or eight inches deep all over the bed, and scatter a little fern, sea thatch, sedge or salt hay over the leaves to keep them from being blown about. Although this may seem to be a heavy mulching, it is none too much, and by next October it will rot down and not be an inch deep.

Summer mulching is far more important than winter mulching. By it we are enabled to grow with fair success shallow-rooting plants and many evergreens that without it could hardly survive our hot, dry weather. Mulch heavily if at all, for this is the only way to accomplish the desired result.

We use leaves only on large beds, and where we can sprinkle a little thatch over them; for small beds and individual specimens we use rough manure or thatch or salt hay alone. But in mulching trees and shrubs judgment must be used. There is no use in describing a circle 6 or 10 feet wide around the trunk of a big tree, removing the sod therefrom and mulching the ground, because the feeding roots have gone beyond that circle, and hence are not under the influence of the mulching. The way to reach them is to top-dress the ground in fall with manure and rake it off level in spring. Some writers argue that if we keep the surface of the ground well stirred by means of the hoe or cultivator in summer this answers every purpose and is better than mulching. That is well enough so far as nursery stock is concerned, but in permanent plantings, for instance in the case of isolated trees and shrubs, and shrubby beds, loosening the surface of the ground should be avoided and mulching adopted.

I have no patience with the people who call out about the unsightliness of mulching. Mulching is repugnant only to the uneducated eye. The person who understands and appreciates the benefit to the plants to be derived from this care regards its presence with special favor. But, of course, it must be neatly applied and kept.

The mulching of trees and shrubs in summer is more extensively practiced in this garden, than, so far as I know, in any other in the country, and we are, year after year, becoming more alive to its beneficial effects. *William Falconer.*

Glen Cove, N. Y.

Grapes for Home Use.

IN response to the inquiry of your correspondent in Northern New Jersey as to the best half-dozen varieties of grapes to plant for family use to the extent of about twenty vines, I name the following and add some reasons why I recommend them.

Moore's Early—two vines—the earliest good black Grape we have. The berries are large; vines hardy, healthy, and productive. The Cottage would prove its best substitute.

Lady—two vines—the earliest good white Grape; very sweet and generally liked. The vine is hardy and healthy, but not as vigorous as many others. The berries are of good size; clusters small, and its season short because of its liability to crack on approaching maturity; but I name it because an early grape of this color is desirable.

Worden—four vines—the best early black Grape; the clusters and berries are large, and the vine is vigorous, healthy, hardy and productive. The above are all of Concord parentage, and like it tender-skinned, cracking easily when ripe.

Brighton—four vines—the best early red grape we have, all things considered. The clusters are large and handsome, berries medium, vine vigorous and productive.

Delaware—two vines—among Grapes what the Seckel and Dana's Hovey are among pears. The small clusters of small red berries ripen early. The vine though healthy and hardy is not a strong grower and does not always find a congenial soil. It is worthy of special care till it gets established and its quality atones for its lack of size.

Wilder—four vines—a large, late black Grape of excellent quality. The clusters are large and handsome; vine vigorous and productive.

Niagara—two vines—the largest and finest white Grape yet tested. Berries and clusters are large and handsome; quality fully as good as that of the Concord—Mr. Downing said better and the vine is very vigorous and productive.

Empire State—two vines—a white grape of excellent quality, better in this respect than the Niagara, but not so large or attractive in cluster or berry. The vine is fairly vigorous and productive.

This list is of course for a special locality, but most of the vines named flourish over a wide area. Brighton, Wilder and Niagara have a little foreign blood in their veins, and are therefore more liable to mildew and rot

than the others which are pure natives, but in seasons favorable to the development of the rot fungus all are susceptible to its attack unless it be Delaware. From the above list your inquirer should be able to choose six kinds, if he wishes to confine himself to that number, but he can plant them all with little risk of failure. They all thrive with me on lower ground and nearer the seaboard, and therefore in a less favorable locality. I do not name the Concord because the season is covered effectually without it. Moore's Early is equally good and two to three weeks earlier, and this is followed by Worden, which is better than either. The season of the Concord is with Wilder and Niagara. *E. Williams.*

Montclair, N. J.

The Forest.

The Hardwood Forests of the South.

THE time seems rapidly approaching when the lower Southern States will furnish the greater part of the lumber shipped from the Atlantic forest region to foreign and home markets, and will take the lead in the various industries which depend for their material upon the products of the forests. From sixty to seventy-five per cent of the area of the several States of the lower South are covered with forests which have been but little encroached upon by the axe. Well timbered countries without the Tropics have at all times been foremost in progressive and varied agriculture and industries. The history of the Old and New World gives ample support to this statement.

With the exhaustion of the forests of White Pine and the denudation of the country north of the Ohio, from the Atlantic border to the Mississippi, where stood a wealth of timber once deemed inexhaustible by men still living, the lumber interests of the country east of the Mississippi are steadily gravitating southwards, and manufacturing enterprises connected with them are seeking the same field. In some investigations made for the Census office in 1880 the writer found the lumbering operations of the great coast Pine belt confined almost solely to the larger streams and to a strip two or three miles on either side of a few railroad lines traversing the forests. A few tram-roads and canals were bringing lumber from remoter parts. But now tram-roads equipped with steam power are penetrating the depths of this forest belt in every direction with astonishing rapidity and are stripping hundreds of square miles of their merchantable timber, and thousands of acres of primeval timber lands are made available by new railroad lines intersecting the forests and helping the transport of their products to the seaboard and the inland markets of the Middle States. The stroke of the axe is now heard from the basin of one river to that of the other where but a short while ago the forest solitude remained unbroken. The shipment of timber and naval stores from the Pine forests of the lower South have doubled in the last seven years, and industrial enterprises based on timber resources have increased many fold in almost every one of the Southern States. Factories of carriages and wagons, agricultural implements, furniture, cooperage and hollow ware, and large establishments for building railroad cars have sprung up with the increase of towns and cities in the mineral districts. The development of the mines of coal and iron has occasioned a great increase of the consumption of timber and fuel. The causes which within a life-time have depleted the timber wealth of many of the Northern States are, at this moment, at work in the South with an activity outstripping that of any former period.

South-western Kentucky, western Tennessee, western North and South Carolina, Arkansas, and the northern half of the Gulf States to the Brazos River, must at present be considered as the great depositories of the timber wealth of the hardwood forest. It is from these Southern forests that the constantly increasing needs of the country are to be met. Experience has proved that timber of southern growth is not surpassed in its essential qualities by that of higher latitudes. In their fullest dimensions and their greatest variety, the most valuable hardwood trees are found in the alluvial bottomlands of the larger rivers toward their lower courses, in the valleys of a higher level, beyond the light silicious soils of the tertiary formation, in the woods covering the lower flanks of bordering elevations and in the narrower defiles of the mountains. The most extensive body of hardwood forests exists in the delta of the Mississippi and Yazoo Rivers in the State of Mississippi, covering four millions of acres, of which one-fifth are in cultivation, and in the alluvial land of the Mississippi and St. Francis Rivers in Arkansas, extending over two millions of acres with scarcely ten per cent of cleared land. The individual trees

here attain dimensions rarely reached by the same species elsewhere, and in wealth of valuable timber trees these forests are not excelled.

Amongst the trees of the highest value and greatest abundance the Swamp Chestnut or Basket Oak (*Quercus Michauxii*) takes the first place. Often a dozen trees measuring two and one half feet in diameter and furnishing clear cuts from forty to fifty feet in length have been counted on a single acre. In quality the wood of this tree is in no way inferior to white oak, and is especially fit for all purposes to which the latter is applied, affording immense resources to the industries depending upon this Oak for their chief material. The Sweet Gum (*Liquidambar styracifolia*) is as frequent here and at its greatest perfection. It is only under these lower latitudes that the timber of this tree attains the qualities which give it economic importance. The wood, of a pleasing reddish brown tint, easily worked, of a fine grain and capable of a high polish, has lately begun to attract the attention of manufacturers of furniture and of the joiner for the interior finish of the best dwellings. Millions upon millions of feet of these valuable timbers are found in these forests, enough to supply the largest demand for many years. Of somewhat less value, the Spanish Oak (*Quercus falcata*), the Willow Oak (*Q. phellos*), the Swamp White Oak (*Q. lyrata*), are to be named, the latter hardly inferior in quality to white oak. To these the Swamp Maple, Water Elm (*Ulmus elata*), Honey Locust, Cottonwood, Pecan, Sassafras and Persimmon, are to be added, the two last reaching dimensions that entitle them to rank among useful timber trees. Most of the hardwood trees peculiar to the lower South, such as Magnolia, Red Bay (*Persea Caroliniensis*), White Bay (*Magnolia glauca*), Sourwood (*Oxydendron arboreum*), and others of lower rank in size, finding at present but little appreciation, will, with better knowledge of their quality, add a variety of useful material for miners' purposes, for the mechanical arts and for decorative joinery.

Difficult of access and remote from active industries, these hardwood forests, still but slightly encroached upon, may be regarded as the chief source of supply for the country's needs for many years to come. Their disappearance is, however, a matter of comparatively short time. Covering lands of greatest fertility, adapted to the cultivation of the chief staple products of this region, their reclamation for agricultural purposes, when protected against the overflowing waters of the Mississippi, is inevitable. The negro population, resisting the malarious influences of lowland clearings, and tempted by good wages and an abundance of food, will be drawn to them to furnish the labor. The movement has already set in during the last few years, and must increase as the colored man comes in competition with the labor of the increasing white population which is taking possession of the healthy upland districts.

With the growing demand for agricultural land following the slow but swelling influence of immigration, the hardwood forests of the valleys of the higher water-level and their terraces and the flanks of the bordering region are equally doomed. Though of less extent as resources of our hardwoods, these forests are of great importance, harboring a still greater variety than the alluvial forests. Preferring the warm and light soil in these districts, the Tulip tree, the White Oak, the White Ash, the Black Cherry, the Black Walnut, are found, in addition to the trees growing in the damp bottom lands, and to these could be added many others of smaller size and less value, as the Beech, Basswood, Butternut, Mulberry, Red Elm, Ironwood, Dogwood and Cucumber tree. The impending denudation of these valleys and of the elevations about them involves the greatest danger consequent upon the destruction of the forests by altering climatic conditions and affecting injuriously the stages of the rivers throughout the different seasons of the year.

The hardwood forests of the more or less broken uplands in connection with farms have in great measure lost the character of the high forest. Deprived of their larger timber, opened to the tramping and browsing of cattle and the visitations of fire, the remainder of the tree-growth presents an unpromising appearance, and in many localities, the second growth is supplanted by Coniferous trees. Immense damage has been done by clearing the steeper and more broken lands and the ranges of hills. Deprived of its productive crust, the bare subsoil of these hill lands, torn into deep ravines, presents a repulsive sight suggestive of barrenness and neglect. Raging torrents after every rain rush unchecked down the declivities, eating deeply into them, carrying the soil down the valleys, obstructing the beds of the rivers and their estuaries.

The timber growth of these upland forests consists of many species of Oaks, as the Black Oak (*Quercus tinctoria*), Post Oak (*Q. obtusiloba*), Spanish Oak, Red Oak, flourishing in a dry, light soil, the Tanbark Oak (*Q. prinoides*), Chinquapin Oak (*Q.*

prinoides), and Scarlet Oak (*Q. coccinea*), found principally on the rocky regions of the mountains. The Mockernut, Pignut and Bitternut Hickories, with the Chestnut and Tulip trees of inferior size, make up a large part of the tree growth. On the table-lands of the coal measures in Alabama, forests of this nature almost in their primeval condition extended over seven thousand square miles. These forests, fifteen years ago scarcely invaded by the small clearings, have, since the beginning of the new industrial era, become of great importance owing to the wealth of coal and iron buried beneath them, furnishing the required supplies of timber and fuel. These forest lands are now much in demand by immigrants, who, by perseverance and industry, make the soil, once considered too poor for cultivation, bring forth profitable field and orchard crops which find a ready market in the growing centres of mining industry which have lately sprung up as by magic in this region. If they are not protected against the destructive influences bearing upon them with increasing intensity as the settlement and development of the country progress, and if the needed care is not extended to the younger growth, the deterioration of these immense forests is destined to proceed surely and steadily to the same destruction to which the forests of the more densely populated districts are doomed. *Karl Mohr.*

Acacia decurrens.—Considerable attention is now being given in France to this Australian tree as a possible source of a supply of tanning material. It thrives everywhere on the shores of the Mediterranean Basin and flourishes in the most arid soils. Mons. Levallois, in a report recently presented to the National Agricultural Society of France, states that a sample of the bark grown at Antibes yielded 31 per cent. of tannin, while recent experiments show that a given amount of the bark was sufficient to cure two-thirds of its weight of leather, while a given quantity of Oak bark would cure but one-fifth of its weight of leather. If further experiments, made on a large scale, confirm the value of the bark, *Acacia decurrens* will prove a valuable tree for southern California and our dry south-western region, where good tanning material is scarce. Indeed the only tree of our Pacific forests which produces really good tan bark is *Quercus densiflora*, of northern California, now becoming rare from excessive cutting.

Recent Publications.

Manuel de l'Acclimateur ou Choix de Plantes Recommandées pour l'Agriculture, l'Industrie et la Médecine, par Charles Naudin. Paris, 1887; pp. 565.

This is a French translation, much enlarged and improved, of Baron Von Müller's well known "Select Extra-Tropical Plants," and is published under the auspices of the National Acclimatization Society of France. By far the larger portion of the work is devoted to a descriptive catalogue of extra-tropical, warm-country plants, valuable to man either from an economic or ornamental point of view, and, therefore, worthy of his attention. This is prefaced by a most interesting study of the general subject of the naturalization and the acclimatization of plants. This last the author describes as "the introduction and successful cultivation of plants valuable to man;" naturalization being the spontaneous spread of foreign plants in a country. As a general rule it is only weeds which become naturalized, but two exceptions are given; the Orange which has reverted to the wild types in Florida, and the Mango which now forms a considerable part of the forest growth in the Island of Jamaica. With these might have been included the so-called Japanese Clover (*Lespedeza striata*, Hook. & Arn.), a valuable forage plant now widely naturalized in some parts of the South, and the common Barberry, now as much at home in eastern New England as in any part of Europe.

A few errors and a few omissions will be detected in the catalogue of plants, but these could hardly have been avoided, although in a second edition it is to be hoped that more of the interesting plants of our south-western boundary may find a place, such as the lovely *Chilopsis* and *Cordia Boissieri*, one of the most showy flowering of North American trees, and considered by the Mexicans of great medicinal value. And in such a work, too, the different species of *Acacia* and *Parkinsonia*, the *Olneya* and the *Fouquieria* of Texas and Arizona, cannot be properly omitted.

The *Manuel de l'Acclimateur* is one of the most important contributions to recent horticultural literature, and its value is all the greater from the fact that the author has cultivated many of the plants he describes, especially the Eucalyptus (a genus to which he has devoted many years of study), in the

gardens of the Villa Thuret in southern France, where he has brought together the richest collection of dry-country plants which now exists. It will be specially serviceable to horticulturists in our Gulf States and in California, where there is still so much to be done in the way of introducing valuable plants.

A Manual of Orchidaceous Plants Cultivated under Glass in Great Britain, prepared and published by James Veitch & Sons of the Royal Exotic Nurseries, London.

Two parts of this work, copiously illustrated, have now appeared. They give good promise of an important and valuable contribution to the already voluminous literature of Orchids, especially in their "cultural notes", which no one can so well supply as can the Veitches out of the long experience of three generations of successful Orchid growers. Part I. is devoted to *Odontoglossum*; Part II. to *Cattleya* and *Laelia*, with *Laeliopsis*, *Tetramicra*, *Schomburgkia* and *Saphronitis*. Capital colored maps show the geographical distribution of these genera. The fact that the two parts are paged separately and that the figures are not numbered, will make it difficult to refer to this book in other publications.

Handbuch der Coniferen Benennung, by L. Beissner, Inspector of the Botanic Garden of Bonn, Ludwig Möller, Erfurt.

This is a list of all Conifers, hardy or half-hardy, in Germany, and is the result of the conference of a Congress of German horticulturists which met at Dresden last summer under the Presidency of the Baron St. Paul, for the purpose of settling the proper nomenclature of cultivated Conifers. This could not have been a very easy task, but the Congress and its Secretary have prepared a catalogue which, with its full synonymy, its very complete lists of named cultivated forms and its full index, will be found a serviceable aid to the students and cultivators of Conifers. It may be noted that *Thuiopsis* and *Chamaecyparis* are retained as genera and not merged with *Thuja*, and that with less reason *Biota* is also separated from that genus. *Wellingtonia* is retained as a genus for *Sequoia gigantea*. We should hardly have expected to have found *Wellingtonia* turning up again at this late day outside of Great Britain, where horticultural patriotism, or whatever it may be, insists on ignoring the older *Sequoia* for our "Big tree" in spite of all the efforts of botanists. *Taxus Florida*, *Juniperus Californica* (except as a synonym of another species), *Pinus Cubensis*, *P. glabra*, *P. clausa* and *P. Chihuahuana*, of the United States Flora, do not appear in the catalogue.

Recent Plant Portraits.

Azalea Indica, Leon Pynaert, *Revue de l'Horticulture Belge*, February.

Oxybaphus Californica (*Mirabilis Californica*, Gray), *Garten Flora*, t. 1266.

Orontium aquaticum, *Revue Horticole*, February 16th.

Platycaria strobilacea, *Revue Horticole*, February 16th.

Phalænopsis, F. L. Ames, *Gardener's Chronicle*, February 18th.

Oxera pulchella, *Gardener's Chronicle*, February 18th; a semi-scandent shrub from New Caledonia, producing immense clusters of pure white flowers. It is closely allied to *Clerodendron*.

Biota (Thuja) Sieboldi, *Gardener's Chronicle*, February 18th. "A form of the common Chinese Arbor-vitæ, in which the young form of leaf is preserved to adult age, the ordinary form of leaf not being produced, and the whole plant forming a compact barrel or flamed-shaped bush of great symmetry and beauty.

Public Works.

Enlargement of the Park of Atlanta, Georgia.—From the Report of the Park Commission of Atlanta it appears that an effort is being made to enlarge the principal Park of that city by securing some fifty acres of land north of its present boundary. The Park now contains but one hundred acres and is manifestly too small for the growing city. An interesting feature of the report is a classified list of the indigenous plants of the Park, prepared by Mr. A. Sidney Rauschenberg.

A Park for Lisbon.—The first prize of 12,000 francs, offered by the City Council of Lisbon for the best plan for a City Park, has just been awarded to Mons. P. Lasseau of Paris. A second and a third prize of 7,500 and 5,000 francs respectively have been given in the same competition to Mons. G. Duchesne and Mons. Eugène Deny, also of Paris.

Flower Market.

NEW YORK, *March 9th, 1888.*

The supply of cut flowers is heavy, but the general stock is poor. Prices continue to decline with all flowers excepting Orchids. *Cypripedium* are in more request than other Orchids, because they combine handsomely with green arrangements, Mignonette being much used for this purpose. *Cypripedium Laurencianum* costs from 75 cts. to \$1.00 a flower; *Cattleya speciosissima* and *C. superba* bring from 50 to 75 cts. a flower. *C. Citrina* and *C. Percevaliana* cost the same. *C. Triana* sells for 75 cts. and \$1.00 a flower, and *Lycaste Skimmeri* brings 40, 50 and 75 cts. a flower. Vandas range from 25 to 35 cts. a flower, with from 4 to 10 blossoms on a spray. *Odontoglossum crispum* costs from 20 to 35 cts. a flower, and there are from 5 to 20 on a spray. *Asparagus plumosus* brings from \$1.00 to \$1.50 a string, and *A. tenuissimus* 75 cts. to \$1.00 a string of 3 and 4 feet in length. Ferns cost from 10 to 50 cts. a frond, *Adiantum Farleyense* being the most expensive. Short stemmed hybrid Roses are selling for \$2.00 a dozen. Only selected Baroness Rothschild and Mabel Morrisons are held at \$1.00 each. Other excellent hybrids bring 75 cts. The best Jacqueminot roses are sold for \$3.00 a dozen and La France for \$2.00 and \$3.00 a dozen. Puritans cost 50 cts. and American Beauties 75 cts. each. Papa Gontiers run very poor; those selected are sold for \$1.00 and \$1.50 a dozen, and the ordinary ones are thrown in with Bon Silenes and disposed of for 75 cts. a dozen. Perles, Niphotos and Souvenirs d'un Ami bring \$1.50 a dozen, and Catherine Mermets \$2.00. Bennetts cost the same. Dutch Hyacinths sell for 15 and 25 cts. a truss; Roman Hyacinths, Lily-of-the-valley, Tulips and Narcissus for 75 cts. a dozen. Specially fine specimens of Tulips and Narcissus Trumpet Major bring \$1.00 a dozen. Lilac costs from 25 to 50 cts. a spray. Heliotrope is 50 cts. a dozen sprays. Pansies are 25 cts. a dozen, and Violets \$1.50 a hundred. Acacia costs from 50 cts. to \$1.00 a spray. Mignonette from 50 cts. to \$1.00 a dozen spikes, and Carnations 50 cts. a dozen for all varieties. *Lilium Harrisii* brings 35 cts. a bloom or \$4.00 a dozen. Callas cost \$3.00 a dozen. Plants of *Spiræa Japonica* appear, but no cut bloom is sold as yet.

PHILADELPHIA, *March 9th.*

Delicate tinted and sweet scented flowers are most in demand just now. There have been some elaborate dinner table decorations, where the very choicest flowers have been used during the past week. Orchids and the rarest Roses only are used on these occasions. Boxes of fragrant flowers are frequently sent to friends at this season—more so than at any other. A few morning weddings have taken place during Lent,—a somewhat unusual occurrence for this city. White flowers were used almost exclusively. On one occasion the corsage bouquets were made of Puritan Roses, as was the centre piece, which was a plateau four feet long. Freesias, Roman Hyacinths, and Lilies-of-the-Valley were also abundantly used. Some large and choice Amaryllises are sold at \$1 each. Single and double Daffodils are called for in about equal quantities. The double Von Sion makes the most show, but the single varieties are selected by connoisseurs. *Lilium Harrisii*, or as it is called generally the Bermuda Lily, has been in good demand at 50 cts. each. The chaste and delicate Cyclamens, both as plants and flowers, are popular, and seem destined in the near future to take a prominent place in the floral world. Pink Tulips are more used than any other shade. More Lilacs would be used if they could be had, but they are scarce. Plants in bloom, such as Azaleas, and what are known as Spring flowers, sell readily. A limited quantity of white Moss Roses are obtainable at \$1 per spray carrying one half-developed bud and several others which have not yet shown color. A few Gloxinias are offered for sale, but they are not in very great demand because they are so easily broken or soiled.

BOSTON, *March 9th.*

The windows of the flower stores are marvels of beauty just now. The display of Roses is especially fine, for at no time of the year are they offered in greater variety or perfection. The various popular hybrid Roses are seen in large quantities, Jacqueminots of course leading, with the beautiful satiny pink Madame Gabriel Luizets closely following, fully as effective in color and almost as popular. Gloire de Paris and Magna Charta are also abundant, but the chief value of these two varieties lies in their easy-forcing qualities, which make it possible to obtain them much earlier in the season than other hybrids. The later kinds are more desirable when they do come. The new Puritan is offered in limited quantities, and when the blooms come perfect, this white Rose is a valuable addition to the list of large flowering varieties. An occasional specimen of that shy beauty, Her Majesty, is to be seen. The color is exquisite, and the flower is of enormous size, but alas! it is odorless. Maréchal Niels are becoming scarce again and the only yellow Rose to be had in any quantity is Perle des Jardins. This and Catherine Mermet hold their price quite steadily, while La France and American Beauty have a downward tendency. Catherine Mermets and Jacqueminots sell at \$2.50 to \$3.00 per doz. Hybrids bring from \$3.00 to \$5.00 per doz., according to variety and quality. Other Roses are worth from \$1.00 to \$2.00 per dozen. Lilies-of-the-Valley and Tulips sell for \$1.00 per doz. Daffodils are held at the same price, but they are getting scarce and cannot always be obtained. Violets and Pansies are worth 50 cts. per bunch. Long Stemmed Carnations, Mignonette, Forget-me-not and Heliotrope bring 50 cts. per dozen. Callas are not as plentiful as they were a week ago and are in demand at \$3.00 per dozen.

Needs of American Pomology.

1. Statistics should be gathered to determine the relative profitableness of fruit-growing in different localities. It is now demonstrated that most parts of the country are adapted to fruit-growing of some kind. For home use and local markets, the cultivation of fruits of all kinds should be encouraged over as wide an area as possible. But there are some fruits whose productiveness varies greatly in different sections, and nothing is gained to the country or the individual by encouraging their cultivation on a large scale in unfavorable situations.

To obtain more definite information than we now have regarding the best situations for the various fruits, statistics of the yield in different parts of the country for a series of years are needed. These statistics might be thrown in graphic form upon a map, showing at a glance the areas over which a given fruit, say the peach, yields a fair crop every year, other areas in which there has been a good crop on an average once in three or five years, and still others in which the trees rarely reach a bearing age. Something of this kind could be done by horticultural societies. Let statistics be taken at a few typical points, such as at South Haven, in Michigan, representing the "fruit belt," and Jackson or Ann Arbor, representing the interior of the State. Similar points for comparison might be chosen in Pennsylvania, Delaware and other States. Information so collected would help to show to what extent the fruits are grown in the locations to which they are best adapted.

2. It is time for an advance in the matter of classifying varieties. The labors of Warder and the Downings need to be enlarged and extended. A reliable manual for the identification of fruits is greatly needed. Some promising systematic work on the cultural varieties of fruits and vegetables has been done, but before satisfactory progress can be made in this direction there must be good herbarium collections of such plants. Cultural varieties are almost unknown in the herbariums of botanists, but collections of

such varieties are a necessity for their proper study. The distinctions between cultural varieties are so much less than those between the natural species and varieties, that for their proper study, it will more often be necessary to refer to the living plants; but the varieties which require to be studied together cannot always be obtained at one time in the living state, nor can they be maintained in the growing condition at the proper stage long enough for that purpose.

3. The systematic improvement of fruits needs more attention. The more promising methods of obtaining better varieties are:

(a.) Selecting the best from among the varieties accidentally produced. In this way nearly all our varieties in cultivation have been obtained. A sharp eye, quick judgment and a taste for trying new sorts are what is needed for this purpose.

(b.) Planting seeds of the best known varieties. Most of these are of short standing; many are of the nature of sports; but the tendency of like to produce like exists to some degree in all of them and renders it probable that the best varieties of the future will come from the best of those we have.

(c.) Better cultivation and changes of soil and climate. Favorable conditions are an important factor in the production of improved varieties. The finest fruits, as a rule, have arisen in the localities best adapted to their growth. Unfavorable conditions may, however, be useful for testing varieties before they are brought into general cultivation, and a long continued breeding up in a given locality may be necessary in order to produce varieties able to withstand extreme conditions, as of cold or drought.

(d.) The improvement of our wild fruits. These, by reason of the long period of their development in the country, are likely to be best adapted to its climate. Our cultivated raspberries and blackberries indicate what may be done in a short time with native species.

(e.) The importation of promising foreign fruits. Most of our cultivated plants are importations. This is not because our native resources of this kind are meagre, but mainly because there has been a longer time abroad in which to develop improved varieties. Further importation of foreign fruits is especially needed, of kinds not native to this country, and from regions having similar climatic conditions.

The Proposed Speed-road in Central Park.

CERTAIN gentlemen of this city who own fast horses have been aiming for years to get possession of a portion of Central Park and convert it into a road, broad, straight and level, whereon their trotters may be speeded, without any annoyance from vulgar animals or their drivers. Some attempts at public meetings have been made in order to invest the project with the dignity of a popular movement; but these have all proved melancholy failures. Nevertheless a bill has been prepared, and is now before the proper legislative committee in Albany, to authorize the construction of such a road, one hundred feet wide, and to compel the people to pay for the work of desolating their pleasure ground. The gentlemen who have tried to organize these meetings for the spoliation of the Park and who are throwing the weight of their influence in favor of this bill are described as "opulent citizens." It does not follow that a citizen is public-spirited because he is opulent, but, as a matter of fact, some of the abettors of this scheme have a certain civic pride and can generally be counted on for the unselfish support of any measure looking towards the city's welfare. It would not be surprising that a man whose loftiest ambition is to be known as the owner and driver of the fleetest trotting horse in the world should be willing to turn the grassy stretches of the Park into a bladeless desert to furnish a track for the exercise and display of this noble animal. The pity of it is that one intelligent and fair-minded man can be found who does not understand that the condemnation of any portion

of the Park to such a use would mean its utter ruin; or who, if he does comprehend this, entertains the belief that the plain people who would be permitted to sit on a bench by the road-side and see him drive by, would, in this way, drink in a delight which would more than counterbalance any loss or pain, caused by a destruction of the pastoral beauty of the Park.

Now, the only reason which justifies the setting apart of so large an area for a park in the heart of a city like New York is, that on ground less spacious, it would be impossible to secure any broad, reposeful examples of rural scenery. As it is, the limits of Central Park are all too scanty. The triumph of its designers' skill lies in the fact that a narrow strip of land, broken and folded into ridges of rock, has been turned into a series of tree-bordered meadows, each one giving glimpses of what promise to be still fairer and more quiet fields beyond. It is this pastoral scenery, and its restful, healing influence upon the minds of those who are worn and wearied with the strained and artificial conditions of city life, which gives the Park its value. This is the fundamental purpose of the Park; and the roads and paths and bridges are only of value as they help the visitor to obtain the refreshment offered by its quiet prospects.

The gentlemen who are able to possess fast horses, do not stand in need of this refreshment as much as some of their less favored fellows. Their winters are passed in the sunshine of the South and their summers in villas at Lenox or cottages by the sea. But to the poor and the children of the poor the Park offers the only glimpse of greensward that greets their eyes from one year's end to the other. It seems a cruelty to destroy these pictures of peace that a wise forethought has prepared for them simply to enable a few "opulent citizens" to enjoy their chosen pastime for a few weeks in the Spring and Autumn. And this is especially true, because the Park and its scenery add nothing to the enjoyment of these horsemen, who find in the driving itself its own exceeding great reward. Some of these gentlemen have famous picture galleries, and all right-minded persons would sympathize with their horror and distress if some vandal hand should cut out a strip from the border of one of their favorite landscapes. But the living picture is just as truly a work of art as the painted one, and the cutting away of this broad stretch of verdure and substituting for it something entirely incongruous with its motive and purpose would be an outrage quite as brutal.

It is discouraging that elementary principles like these need to be stated now after the Park itself has been for thirty years pleading its own excuse for being. But there are men who do not hesitate, when their minds are filled with the clamors of a controlling passion, to argue in favor of some encroachment upon the Park that "it was made to use and not to look at." The notion at the bottom of this is, that the only legitimate use to which land in a city can be put is to be built upon or trampled over, or in some way "improved" or occupied. Even a Park Commissioner who had a scheme to fill up one of the fairest vales of Central Park with cheap carpentry once justified his purpose by calling the spot "a piece of unimproved land." So long as it is not recognized as a principle of action that beauty may be in itself of the highest use; so long as it is not understood, that from the most practical, common sense view, the primary "use" of a pleasure ground like Central Park is "to be looked at," just so long every urban park in the country is threatened with destruction.

There is no need therefore to state here the special objections to this speed-road. There are difficulties in law to be urged by those who have the right to enter the Park and cross this track. There are enormous difficulties in the way of its construction. There are difficulties which would destroy its value as a track for fast driving even if it could be built. But these special objections might not hold against the next threat of invasion; and one encroachment will certainly be followed by another, for there are a hundred classes of people—each with a claim upon the

city's pleasure ground as valid as that of the fast drivers—and every one will feel encouraged to pre-empt a quarter section here or there for the special business or pleasure in which its members are chiefly interested.

What is needed most is intelligent opinion as to the primary uses and purposes of well-planned and planted parks. Their value as breathing spaces, as aids to purify the air, as places for exercise, is constantly and properly urged; but it is only when their higher function, their healthful influence upon the mind, is universally appreciated, that the foundation is laid for the strongest resistance against attacks upon their integrity.

Ghent Azaleas.

G HENT Azaleas, as they are generally known in horticultural literature, are a race of garden hybrids produced in the first place by crossing *Azalea Pontica* with different American species, especially *A. calendulacea*, *A. viscosa* and *A. nudiflora*, and then improved by selecting the best varieties raised from the seed of these hybrids. They are, perhaps, when in flower, the most beautiful of all our hardy shrubs. They are equally beautiful when massed in great beds or when grown singly. Their brilliant, deliciously fragrant flowers range in color from crimson and pink, through orange and yellow to almost white. No plants bloom more freely and few last longer in bloom. These Azaleas flourish in good garden soil, but like the evergreen Rhododendrons, they cannot bear lime, and the region where they can be grown in the United States therefore is not very large. Although the plants are all perfectly hardy, the blossom buds of some varieties are killed in severe winters and some grow less vigorously than others.

The following varieties, selected for a large collection, are hardy, vigorous and free blooming, their flower buds never suffering in the most severe winters: Henry Waterer, Belle Merville, Heureuse Surprise, Madame Baumann, Fama, Gloria Mundi, Astreans, Grand Monarque, Pallas, Beauté Celeste, Prince Henri de Pays Bas.

Hardly inferior in beauty to any of the varieties of this garden race is our native *Azalea calendulacea*, and one of the great sights of this continent for the lover of flowers is the slopes of the Southern Allegheny Mountains when they are blazing in June with the great flame-colored masses of this splendid plant.

But these hybrid Azaleas can, perhaps, be still further improved, or their blooming period, at least, greatly extended, by mingling with them the blood of *Azalea arborescens*, a very late-blooming, hardy species, with white, fragrant flowers, from the Carolina Mountains, and of the Californian *A. occidentalis*, another late blooming species. Their further improvement offers an inviting field of experiment.

These plants are spoken of here as Azaleas; in reality they are all Rhododendrons, for *Azalea* only differs from *Rhododendron* in its deciduous leaves, a view now accepted by botanists, but, in speaking of them from a cultural point of view, much confusion will be saved by retaining *Azalea*, the name by which they are universally known in gardens.

Landscape Gardening.—IV.

I T has been said that though the landscape gardener works with Nature's own materials and processes, he does not lack those opportunities for self-expression, which alone make art a possibility. His task is to produce beautiful compositions—beautiful pictures. Nature supplies him with his factors—always gives him vitality, light, atmosphere, beautiful colors and charming details, and often lovely or imposing forms in the configuration of the soil; and she will see to the perfect finishing of his design. But his design is the main thing and must be of his own conceiving.

It is easy to see that this is true when it is a question of formal, "architectural" design in gardening. But it is just as true when it is a question of the most "natural" landscape work. Nature seldom shows the artist a large composition which he can wish to reproduce; and if by chance she does, it is impossible for him to reproduce it. Practical difficulties hedge him narrowly in, and appropriateness—which in every art is a prime consideration—controls his efforts more imperiously than those of most other artists.

If the painter finds a natural scene which, without alteration, would please him upon canvas, he can paint it as he finds it and take his picture where he will. If Nature will not help, she will not hinder him, nor will appropriateness forbid his savage, or his arctic, or his tropical landscape to hang upon a wall in Paris or New York. But the gardener cannot reproduce such a landscape if he would, and appropriateness would forbid him if he could. He cannot even reproduce a scene nearer home, the appropriateness of which, in general effect and in details of vegetation, might be entire. His aim is never purely ideal; he can never think simply of beauty or even of appropriateness in the abstract. He may practice with abstract problems on paper, but with each piece of his actual work Nature says to him: Here in this spot I have drawn a rough outline, which it is for you to make into a picture. In many other spots I have shown you scattered beauties of a thousand kinds. It is for you to decide which of them you can bring into that picture, and for you to discover how they may be fused into a whole "which shall look as beautiful, as right, as though I had created it myself."

Thus we see that appropriateness must be the touchstone as regards not only general effects, but particular features. The memory may be stored with endless beauties that Nature has revealed—with innumerable "bits" of composition, with pregnant ideas for foregrounds, backgrounds, middle distances and "effects" of every sort, and with exhaustless materials in the way of trees and shrubs and flowers. But not one can be used without bringing the mind to bear upon the questions: Will it, theoretically, be appropriate in this part of the world? Can I, theoretically, introduce it into a creation of this special sort? And will practical, local considerations permit me to introduce it, if I find it theoretically appropriate? Indeed, the true process of landscape creation is more synthetical, more imaginative than this. The true artist will not go about with a store of ready-made features and effects in his mind and strive to fit them into the composition of the moment as best he may. He will conceive his general idea in deference to the local prescriptions of Nature; develop his general scheme as artistic fitness may seem to counsel; discover the special features and details which are needed to perfect it (considering which Nature will permit among those that he might desire); and then, half unconsciously perhaps, search for memories of natural results which may teach him how to achieve his own. In educating himself he will have tried less to remember in a definite way those particular results of Nature which he may have seen than to understand how Nature goes to work to produce beautiful results—to permeate himself with her spirit, to comprehend her aims, to learn what she means by variety in unity, by harmonious contrasts, by appropriateness of feature and detail, by beauty of line and color, by distinctness of expression—in a word, by composition. He will have tried to train his memory of general rather than his memory of particular truths, and chiefly to purify his taste and to stimulate his imagination;—for he will have known that, while in some ways he is Nature's favorite pupil, in other ways she treats him more parsimoniously than the rest. She gives him a superabundance of models by the study of which he may make himself an artist; but when as an artist he is actually at work she will never give him one which, part by part, can guide him in his effort. When we read of painters we marvel most not at the modern "realist" working inch by inch from the living form, but at

Michael Angelo on his lonely scaffold, filling his Sistine ceiling with forms as true as Nature's, and far more powerful and superb—no guides at hand but his memory of the very different forms he had studied from the life and his own creative thought. Yet something very like this is what the landscape gardener must do every time he takes a piece of work in hand. Certainly not each of his tasks is as difficult as a Sistine ceiling, but each, whether small or large, whether hard or easy, must be approached in the same way that this ceiling was approached. Is his work not, therefore, pre-eminently artistic work? Does it not give him full chance to express himself since it calls so imperatively at every step for the exercise of the imagination, and since the best memory in the world can only give him general, and not special, counsels?

M. G. Van Rensselaer.

Horticulture in Florida.

THE cold wave which swept over Florida in January, 1886, marked the beginning of a new epoch in her development. Before that time orange culture had been made to advertise the State so extensively that it had come to be regarded as the all-important industry, and thousands even of her inhabitants looked upon it as the only one that could be carried on with profit here. Therefore this killing frost was regarded as an unmitigated disaster. True, the groves within the orange belt proper were not seriously damaged, but a cloud was cast on the title of the orange to public confidence, and the result has been that for the past two years Florida has suffered partial eclipse. But there are strong indications that the obscuration will not last much longer.

The orange fever will hardly be revived and it is far from desirable that it should be. While it continued we suffered all the evils of a one-crop system. Besides, it diverted immigration from that large portion of the State where oranges cannot be grown with profit, but where people can more readily make a living by mixed agriculture. The great freeze, therefore, did some good in checking rash investment and reckless planting and turning people's attention to more substantial branches of rural industry.

Besides the orange no fruits had obtained much favor in Florida before 1886, except a few of a still less hardy nature. For a few years the Lemon had been planted largely in southern Florida and the fruit was shipped in considerable quantity. Being less perishable, it promised soon to rival the orange in public favor. The Lime succeeded finely in the same region, as did the Grape fruit, Citron and Shaddock, but they were but little grown except for ornament and home use.

In the orange belt the Guava (*Psidium pomiferum* in varieties, and to a less extent *P. Cattleianum*) had come to be regarded as a standard fruit, and deservedly so, for there is scarcely another that can be put to a greater variety of uses, or used more months in the year. In 1885 it was plentiful in the Jacksonville market, but it could hardly be shipped fresh out of the State. These with Bananas (planted mainly for ornament), Figs, improved native Plums (*Prunus angustifolia*), the Scuppernong Grape, and more rarely some inferior Peaches and Pears, the Japan Persimmon, the Loquat (*Eriobotrya*) the Mulberry, Pomegranate, and a few varieties of improved Grapes, comprised the minor fruits of the Citrus belt.

The Coconut and Pineapple, formerly confined to the southern keys, were coming into notice as fruits adapted to the latitude of Lake Okeechobee, and the latter fruit had succeeded well on the eastern coast as far north as Cape Canaveral. The Mango (*Mangifera Indica*) and Avocado Pear (*Persea gratissima*) had fruited bountifully as far north as Tampa. These and other sub-tropical fruits were planted still further north, and there was a growing disposition to put them to the severest test in a climate subject to a lower range of temperature than they could by nature endure.

Such was the situation when the memorable cold wave swept over us, driving the mercury down to a lower mark by four degrees than had been known since 1835. To make matters worse this cold wave was of twice the usual duration, which is two days. All Citrus fruits that had not been gathered, except in the southernmost counties and on the Indian River, were frozen. The Orange groves which had been the pride of Florida, were stripped of their foliage and remained bare and dreary during the remainder of the winter. Weak trees were seriously damaged, as were Lemon and Lime trees, while Guavas and the whole list of sub-tropical fruits were killed to the ground.

Native trees of sub-tropical species, such as the Black Mangrove (*Avicennia nitida*) and the Rubber Tree (*Ficus aurea*), some of them fifty years old, were killed, proving the exceptional severity of the weather. North of latitude 30° on the Atlantic side of the peninsula, and 29° on the Gulf side, neglected and unprotected Orange groves were badly damaged, while some even on the northern border of the State were scarcely injured, except by loss of foliage, which began to put out again in March.

This event, occurring at the beginning of the tourist season, and when southern California had just become accessible to tourists, proved disastrous to Florida in its immediate effects; yet looking toward the ultimate welfare of the State, it must result beneficially. The Orange has shown itself to be much harder than was supposed. Attention has been turned from sub-tropical fruits, and in seeking for substitutes many hardy fruits have been brought into notice, which will add greatly to the people's comforts and sources of income. Faith in the one-crop system has given place to desire for greater variety. The people have been led to inquire and experiment, and by this means have come to know that the orange belt, as well as the cotton belt of the State, is adapted to a great variety of profitable and attractive industries. That some progress has been made in the way of fruit-growing will be shown in another letter.

A Disease of Certain Japanese Shrubs.

JAPANESE shrubs form, as every horticulturalist knows, conspicuous ornaments of modern gardens, and are in many cases to be regarded as indispensable. All that concerns them is, therefore, of interest, and details of the experience even of a single amateur may not be without interest. In my own garden at Newport, R. I., the exposure is towards the east, and the distance from the sea-beach about one-eighth of a mile. The soil is light, but fairly good, with underlying clay. The prevailing wind during the greater part of the year is from the south-west. The average winter temperature is higher than 20° F. Lower temperatures are not very frequent, but temperatures as low as 0°, or even lower, do occur, though not for more than one or two days at a time, and not more frequently than once or twice in the course of a winter. The spring is always very cold and late—a fact which was noted by Bishop Berkeley during his residence on the island in 1728-34. For a number of years I have observed that spring arrives at Cambridge, Mass., nearly a fortnight earlier than at this place. Warm days in April are very often followed by very cold nights. The cool and delightful summer is followed by a long, very cool autumn, not favorable to the perfect ripening of bulbs.

I have for some years cultivated Japanese and Chinese shrubs with an especial predilection, and have noted the following curious fact in regard to a number belonging to different natural orders: Some time in July or August the tips of the new shoots begin to look sickly, then wither, turn brown and finally die down to the root, leaving a number of other branches in a healthy condition. This I have observed in *Rosa rugosa*, *Cercis Japonica*, *Acer polymorphum* and varieties, *Exochorda grandiflora* and *Staphylea Bumalda*. I have not been able to detect the presence of any insect, and have found no remedy, except the heroic one of cutting out all affected branches. As a rule the root remains sound and sends up new shoots during the ensuing spring. *Exochorda grandiflora* has suffered most and for several successive seasons. The disease showed itself for the first time in the summer of 1886 in an old and very large group of *Rosa rugosa*, and again during the past summer in some much younger plants. *Cercis Japonica* is not hardy here, but is killed to the ground every spring. The new shoots invariably begin to die down in July. *Viburnum plicatum* is not affected, and I have not observed the disease in *Anapelsis Veitchii* or in *Cercidiphyllum Japonicum*, *Rhodotypos Kerrioides*, *Hydrangea paniculata grandiflora*, *Actinidia polygama*, *Akebia quinata* or in *Eleagnus longipes*, which last summer bore a prodigious crop of an agreeable acid fruit. I have already stated that on this island very warm days in April are often followed by very cold nights. Two years since beautiful hedges of *Lonicera Halleana* were killed, root and branch, by alternate heat and cold in April, while *Lonicera Japonica* and *Lonicera brachypoda aureo-reticulata* also suffered severely, although in a less degree. It may prove that the disease which I have observed is also due to alternations of heat and cold, and perhaps that it is analogous to the frozen sap-blight which affects the pear.

Foreign Correspondence.

The Kew Arboretum.

THE living collection of trees and shrubs in the open air at Kew is by far the most extensive of any in Europe. It is intended in these notes to give an account of the most remarkable specimens of this famous arboretum, but it seems first of all desirable to give a sketch of its history, so that some idea can be formed of the way in which, from a small beginning, Kew has attained its present importance. About the middle of the seventeenth century Kew—and this short, familiar name I shall use to designate the Botanic Gardens and Arboretum—belonged to a gentleman named R. Bennett, whose daughter and heiress married Lord Capel, who died Lord Deputy of Ireland in 1696. Lord Capel in reality was the first to begin the formation of a botanical collection by importing rare trees and shrubs from France. It was not, however, until a long lease of Kew had been obtained from the Capel family by the Prince of Wales that much was done in altering and laying out the grounds. The mother of George III., Augusta, the Princess Dowager of Wales, some years after the death of her husband, resided at Kew, and decided to make a botanic garden. In this work, which she took great pleasure in personally superintending, she received much assistance from the Earl of Bute, a liberal patron of men of genius, both in literature and in the arts, but probably the most unpopular English minister of modern times. It may be worth mentioning here that Lord Bute's favorite study was botany, and that he published a quarto work in nine volumes, entitled "Botanical Tables," a whim which it is said cost him £10,000; only twelve copies were printed.

In 1759 William Aiton, a pupil of the celebrated Philip Miller, the friend and contemporary of Linnæus, was placed in charge of the gardens. Aiton laid out and planted as an Arboretum, according to the Linnæan system, a piece of ground about five acres in extent. Many of the finest foreign trees were contributed in 1763 from his garden at Whitton by Archibald, Duke of Argyle, surnamed by Horace Walpole, the Tree-monger. The following testimonial to the ability and character of this nobleman is given by Peter Collinson (the friend and contemporary of Linnæus), a famous old gardener, who was the first to introduce to cultivation in Britain, through his friends Bartram, Catesby, and others, a host of North American trees, shrubs and plants: "The Duke of Argyle, on the 15th of April, 1761, died as he sat in his chair, my honored friend and great patron of all planters, aged 79, a very hearty man of that age. In the year 1723-4 he took in a part of Hounslow Heath, to add to a little farm, and began planting by raising all sorts of trees and shrubs from seeds from our northern colonies and all other parts of the world; he had the largest collection in England, and happily lived to see to what a surprising maturity they had arrived in thirty-seven or thirty-eight years. Great was his benevolence, for he gave to every one to encourage planting, and raised plants on purpose to oblige the curious at this seat of his, called Whitton. He had a fine collection of rare birds and beasts; he was a great chemist, natural philosopher, mechanic, astronomer and mathematician. He was a wonderfully amiable man, plain in his dress, without pride or vain ostentation; his library was scarcely to be equaled. He was 41 years old when he began to sow seeds for his plantations." Several of the trees presented to Kew by the Duke of Argyle are still flourishing in their original positions, and a detailed account of some of them will be given by and by.

It would be a waste of time to give minute details respecting Kew and its fortunes between the periods mentioned above and 1841, although there is not the slightest intention to underrate the services of the second Aiton, nor of his able colleague, Mr. John Smith, A.L.S., who is still hale and hearty, and takes a lively interest in all matters

horticultural.* The next step of most importance was the appointment of Sir W. J. Hooker in 1841. The greater portion of what is now the Arboretum was then called the Pleasure Grounds, and was simply nothing more or less than a game preserve. The new Director lost no time in calling the attention of the government to the cramped accommodation for the hardy ligneous collections, and urged the formation of a National Arboretum. A plan was drawn out by Nesfield, one of the foremost landscape gardeners of his time, and the lines laid down by him have in a broad sense been followed. When Her Majesty relinquished the grounds in 1840 the "Board of Green Cloth" ceased to control the destinies of Kew, and it was placed under H. M. Commissioners of Woods and Forests. In 1843 permission was granted to utilize a piece of ground measuring forty-eight acres as a pinetum; of this plot the noble palm house may now be said to form the centre. A considerable number of fine Conifers still exist of those planted at that time. Not until 1850 were the Pleasure Grounds—more than 178 acres in extent—diverted from their use as a game preserve and devoted to their present purpose. For some time before the appointment of Sir W. J. Hooker, Kew had languished for want of efficient support, but ever since that event the establishment has progressed by leaps and bounds. After the death of Sir W. J. Hooker, his son, Sir J. D. Hooker, reigned in his stead, and no one in the scientific world is unaware of the services rendered to horticulture and botany by the late director. The appointment of Mr. W. T. Thistleton Dyer to his present post is a comparatively recent occurrence, but the works carried out by him sufficiently prove that the establishment will develop still further and will maintain its position at the head of the botanic gardens of the world.

Kew, February, 1888.

George Nicholson.

Floral Notes from London.

A new race of hybrid *Begonias* has been originated by the Messrs. Veitch, of Chelsea, which promises to become of considerable value for winter flowering. The foundation of this race is the new *Begonia Socotrana*, which was discovered and introduced a few years ago by Professor Balfour when exploring the little known island of Socotra in the Gulf of Aden. This species is distinct from other cultivated *Begonias*, having shield shaped or round leaves, and flowers of symmetrical outline about one and one-half inches across and of a bright rose-pink. It flowers naturally in winter, and so it occurred to the Messrs. Veitch that a good result could be obtained by intercrossing the Socotra *Begonia* with some high colored varieties of the South American species, especially with those having distinctly tuberous roots and which bloom in summer. The first attempt resulted in the production of a pretty variety showing intermediate characters between the parents. It had more rounded leaves than its parent, *B. insignis*, while its flowers, though smaller than those of *B. Socotrana*, were more highly colored. It was named Autumn Rose because it began to flower in autumn and continued nearly throughout the winter. The next cross of *B. Socotrana* was with a tuberous variety, and the pretty hybrid named John Heal resulted. It is a dwarf compact plant, producing flowers very freely, and continuing in bloom through the winter. The flowers are of a bright cherry-crimson. A third variety is named Adonis, which has much larger flowers than the preceding two, more regular in form and of a pleasing rose-pink. The most recent hybrid is called Winter Gem, a cross between *B. Socotrana* and a highly colored tuberous variety. It has large, bold leaves, almost as round as those of the Socotra *Begonia*, and large flowers of good shape of a bright rosy-crimson borne well above the foliage. Messrs. Veitch have a large number of seedlings yet to flower, and judging by the rate of advancement in the few hitherto produced, some good things may be expected.

The White Bornean Jasmine is one of the loveliest and most fragrant plants one can grow for a continuous supply of cut bloom during winter. At least, it is so here, and, no doubt, the plant would behave as well in America. It is rather a new plant, introduced by Messrs. Veitch a few years ago

* Since the above letter was written the veteran ex-curator of the Royal Botanic Gardens has passed away at the age of ninety years.—E.D.

from Borneo. It has a tendency to climb, its shoots being slender and rambling. It flowers abundantly; every twig bears a cluster of blossoms. It delights in a warm and moist house, and if in a light position will produce a continuous crop of bloom for several weeks.

The Double Chinese Primula, *Eva Fish*, is not a new variety, having been put in commerce years ago by Messrs. Henderson, but rarely, if ever, has it been seen in such perfection as at an exhibition of the Royal Horticultural Society at a late winter meeting, when it was honored with a certificate. It is distinct from all the others in point of color, which is a sort of plum-purple. The flowers are very large, perfectly double, being, in fact, like compact rosettes, and are borne in great trusses, rising well above the luxuriant foliage. There is no other double Primula of a similar color to compare with this one, and it will probably become even more popular than heretofore. Each flower of the double Primula makes a neat buttonhole bouquet and they are much used for this purpose.

Wm. Goldring.

Plant Notes.

Hardy Begonias.—Mr. Pringle's note concerning the rediscovery of *Begonia gracilis* in Northern Mexico, reminds me to ask why the old hardy *Begonia Evansiana* (*discolor*) is so much neglected. I once had a bed of these plants in northern Maryland, which occupied the same spot for eight or ten years. The bulbs were occasionally lifted and reset, as they became too thick in the bed, but had little other attention, being treated as a little group in the shade of trees in an out-of-the-way place. The plants came through a temperature of 18° below zero in 1880, without any covering. My practice was to plant early Tulips among them, in the fall, to make a bit of early color, and by the time the *Begonia* leaves appeared above ground the Tulips were ready to be lifted. In autumn the bed was a mass of rosy bloom, until frost cut the flowers down. I have never seen it planted elsewhere, and it is now hardly known except in old green-houses, where it sometimes becomes almost a weed from the dropping of the bullets from the axils of the leaves. It is far more reliable as a bedder than any *Begonia* I ever used.

Crozet, Va.

W. F. Massey.

Grevillea Thelemanniana.—This elegant little Proteaceous plant is one of the prettiest of the genus, and a native of Australia. It attains a height of three to five feet, and has slender, drooping branches, terminated by pendulous racemes of bright red flowers tipped with yellow, their beauty being enhanced by the delicate pinnate leaves. Although a scarce plant it is a comparatively easy one to grow, and will do well in company with Azaleas. It should be potted in a compost of equal parts of peat and loam with a good sprinkling of sand; care should be taken not to give it too much pot-room. During the winter months—which is the time the flowers generally appear—the plants should be kept comparatively moist at the root, but the atmosphere of the house should be dry, and a temperature from 45° to 55° maintained. The *Protiacææ* are not so popular as they should be, probably on account of the extra attention the plants require during the hot days of summer, when neglect of watering may result in their death. A good plan in summer is to plunge the pots to their level, out of doors where water is handy. This species is easily increased by cuttings of half-matured shoots inserted in sand in a cool house.

F. Goldring.

Allium Neapolitanum is the prettiest white flowering species of the genus, a native of southern Europe, barely hardy here, but well fitted for pot culture. We had it in capital bloom in February in a cool green-house. The bulbs are roundish, very small and silvery gray, the foliage is flat and moderately broad, and the flowers quite pretty, white and loosely arranged in full umbels terminating a scape some fifteen inches long. The plants set and ripen seed freely and by sowing this seed a fresh stock of the plants can be readily secured.

Ornithogalum Arabicum.—Dry bulbs of this plant potted last October and then grown along in a cool green-house are now in bloom. The flowers are large, white with black centres, showy and in flat-headed racemes terminating scapes, some eighteen to twenty-four inches long. The foliage is long, flat and slender, but I cut it into about half its length and in this way secure a tidy form. This species and *O. lacteum*, from South Africa, are the best for pot culture, and both are easily grown. W. F.

Akebia quinata.—In Philadelphia we can grow, with a little protection, many of the southern vines, such as the Carolina Jasmine, *Berchemia volubilis*, *Bignonia capreolata* and *Decumaria barbara*, a privilege denied to many but a few degrees north of us. But after all we could hardly spare the useful and pretty *Akebia quinata*. Its trifoliate leaves, though apparently so tender, when young, are sturdy enough for any weather, and the plant itself defies our most severe winters. Its rapid growth, and its early plum-colored flowers with their delicious fragrance make it altogether desirable. When planted where thick, yet not dense, shade is required, no vine is more effective. It rarely produces fruit here, yet on several occasions specimens of the fruit have been exhibited at our Horticultural Society. One of the best ways to propagate the *Akebia* is to take half-ripened wood in midsummer, cut into lengths of from one to two eyes each, and insert them in pans of sand and water.

Joseph Meehan.

bright purple. The flowers are so placed as to resemble a flying bird, and justify the popular name of "Bird of Paradise Plant."

W. A. Manda.

Wayside Beauty.

IN these days there is no lack of advice to plant trees by every roadside, and Village Improvement Societies are furnishing good examples of neatly kept highways. But many of our country roads are already bordered with trees and shrubs and climbing vines of Nature's own planting, and it is quite as important to preserve the wild beauty of this spontaneous growth as it is to provide for the more formal and stately rows of Elms and Maples which are planted on Arbor days. The illustration below gives a glimpse of a New England by-road which, fortunately, has escaped the axe and brush-hook of the enterprising path-master. Many officials in charge of our highways

A Country Road.

Strelitzia augusta.—Most gardeners are familiar with the *Strelitzia Reginae*, generally cultivated and flowered in our green-houses, but the plant named above is rarely seen and still more rarely in flower. It does not bloom until it is from fifteen to twenty-five years of age, but afterwards it keeps pushing up its curious spathes of flowers which last long in perfection. Aside from the showy flowers which are produced nearly the whole year round, its stately form and large leaves make it conspicuous. Those only can enjoy its possession, however, who have large green-houses, for the plant grows from 15 to 20 or more feet in height. Its culture is simple. It flourishes best if planted out in the green-house in a good, rich compost of loam, sand and leaf-mould, and in this way it will take an unlimited amount of water. It can be grown from seed as well as from offshoots which are produced from the base of the plant. It is related to the Banana which it resembles in appearance and structure. The stem is marked with irregular rings where the leaves have separated. The leaves are large, oblong-lanceolate and slightly arching. The stout scape branches out into three or four spathes resembling small canoes, from which the flowers are produced in succession. The three nearly equal sepals are eight inches long and pure white, while the two halbert-shaped petals are smaller and

appreciate the value of trees when planted in straight rows and at equal distances, but a group of Cockspur Thorn, or Sassafras, or Black Haw, or a thicket of Sumach, or Hazel-nut, is too often looked upon as a disfigurement and a proof that the overseer is neglecting his duty to keep the roadside neat and clean. Miles on miles of wayside beauty are sacrificed every year to this mania for "trimming up," but the trees and shrubs spring up again to clothe the desert made by man. In smooth and level regions a strip of greensward bordering the wheel-way and running under the open fences into adjoining fields is always pleasing, and it cannot be too neatly kept. But in all hilly and stony regions east of the Alleghanies, no lovelier road-border can be conceived of than the native trees and shrubs which flourish wherever they are left to themselves. Every one recalls some narrow lane or by-way, with fern-embroidered thickets on either hand, where the June Berry and Wild Plum and Witch-Hazel blossom above the Roses and Honeysuckles and Red-root; where the Wild Grape covers the nakedness of the stone walls and the Bitter-sweet swings from the branches of the trees overhead; where wild flowers can be found in bloom any day between April and November; where the brown thrush sings and the rabbit makes her home. Indeed, it would be difficult to name a spot where there is

more of natural beauty and melody and fragrance than a country roadside against which the hand of improvement has not been lifted.

Iris bracteata.*

AMONG the peculiar species of the genus *Iris* which are found upon the Pacific slope of North America, the one here figured is one of the more notable and interesting. From near the extremity of its slender rootstock it sends up a flowering stem which is covered by loose sheathing and overlapping bracts, purplish, and scarcely differing from the bracts which subtend the flowers. The flowers are usually large, either nearly pure yellow or the recurved sepals (or "falls," as they are sometimes called), veined with bluish purple. The tube of the flower is very short and funnel-shaped, and the sepals, as in all Western species, are without beard or crest. The petals are narrow and erect, and the narrow styles are much prolonged beyond the anthers. The leaves that arise from the rootstock are solitary, at first sheathed at base by several thin, equitant bracts which appear to soon dry and wither. The leaf itself is linear and taller than the stem, thick and leathery, and persistent to the second or third year. When dry, the margins become revolute as a consequence of a dissimilarity in the two surfaces. The ordinary equitant leaf of *Iris* is as if it were folded longitudinally upon itself, so that the two surfaces are identical in character. Here, while one side is smooth, close and bright green, as usual, the other is lighter colored, with a very thin cuticle crowded with stomata, making it, of course, much more hygrometric.

This species was found by Mr. Thomas Howell, of Arthur, Oregon, in 1884, in the mountains of Josephine County, very near the southern boundary of that State, flowering in the latter part of April and in May. In 1887 he again visited the locality and secured roots, from which it is hoped that the plant may be introduced into cultivation. In its characters it is most nearly allied to *I. Douglasiana*, which is common in the Coast Ranges of California from Del Norte to Alameda County. That species is much more leafy, and the usually pale lilac flowers have a much longer and narrower perianth-tube. The accompanying figure is from a drawing by Mr. C. E. Faxon. S. W.

Sweet Peas.

OUT of thirty-one named varieties of Sweet Peas, planted for trial last year, I found but nineteen really distinct kinds. Cardinal was practically identical with Invincible Scarlet; so was Princess Louise, with The Queen; Queen of the Isles, with Invincible Red Striped; Violet Queen and Grand Blue, with Light Blue and Purple; Purple Striped, with Black and White; Captain Clark and Lotty Eckford, with Blue Edged.

Princess Beatrice is one of the most beautiful, with large, clear rose-pink flowers. Miss Ethel and Isa Eckford are nearly identical with it, but somewhat inferior. Adonis is similar, but darker, a deep carmine-pink. The Queen has a standard of deep rose, tinged with purple, and darker wings—a finely-formed flower, a trifle dull in color. Vesuvius is quite distinct, with standard of rosy-crimson, lighter at the edges, spotted and veined toward the centre with darker color, and wings of rosy purple, spotted like the standard.

Of scarlets, Invincible Carmine is the best, being an improvement on Invincible Scarlet, with broad standards, the rich color deepened in the wings and heavily shading the keel. Duchess of Edinburgh is similar, but with standard of lighter color and a white keel. Scarlet Striped has a white ground shaded and striped with scarlet, while Invincible Red Striped has scarlet ground, striped and blotched with white.

No pink and white variety is as good as Painted Lady, though Crown Princess of Prussia is beautiful, but of lighter color. Captain Clark has a white standard shaded with rose and veined with dark lines, and white wings tinged with rose and edged with purple. Fairy Queen is nearly pure white, with a few delicate, crimson veins in the centre of the standard. Butterfly is white, faintly edged and shaded with blue.

Among the blues, Bronze Prince is an improvement on Indigo King, having better formed standards, the purplish crimson distinctly tinged with bronze. Violet Queen shows a

Fig. 8.—*Iris bracteata*.

**I. BRACTEATA*, Watson, *Proc. Amer. Acad.*, xx. 375. Rootstock slender; leaves solitary, rigid, much exceeding the stem (one or two feet long by half an inch broad or less), striate, one side green and the other glaucous, revolute on drying; stem angled, covered with imbricated sheathing bracts two to four inches long; bracts of the spathe approximate, thin-foliaceous, two or three inches long, two-flowered; perianth-tube short, funnel-form; sepals oblong-obovate, two or three inches long, recurved, yellow, usually veined with bluish purple; petals erect, oblongate, somewhat shorter; anthers longer than the filaments; styles long-crested; capsules exserted, ovate-oblong, an inch long.

Fig. 9.—Chinese Narcissus grown in water.

reddish violet tinge in the wings, and Imperial Blue shows more blue than others of this class. Princess of Wales and Purple Striped are the best of the dark-striped varieties, the one blue and white and the other purplish crimson and white.

The most useful of all for cut flowers is the old Pure White. Unfortunately it is a rather poor grower, and therefore the announcement last year that an improved variety of Pure White had been shown at an English exhibition was gratifying to all who take a special interest in these beautiful and fragrant flowers. Other new varieties at English exhibitions, spoken of as distinct and promising, are Primrose, Mauve Queen, Splendor and Apple Blossom, whose names give some indication of their color.

A. H. Fewkes.

"It cannot be too often repeated that care should be taken not to willfully destroy the native features of the scene. Many gardeners assume that before beginning their plantings they must dig up everything that Nature has made to grow; whereas experience proves that they would accomplish their end much sooner and better if they should try to second Nature by making slight changes here and careful additions there."

From C. C. L. Hirschfeld's *Theorie der Gartenkunst*, Leipzig, 1777.

Polyanthus Narcissus.

THE ancient Chinese custom of growing the Polyanthus Narcissus in water to bloom at the advent of their New Year was brought to San Francisco by emigrants from the Celestial Empire more than a quarter of a century ago. The fashion has now reached the east, and it is not very uncommon to see this plant growing in this way in the houses of Boston and its suburbs. The cultivation of the Narcissus in water is very simple. The bulb is placed in a shallow bowl or deep plate, about six weeks before it is wanted in flower, and, according to the Chinese habit, is surrounded with small bright-colored stones probably to prevent it from tipping in the plate; this is filled with water and should be placed in the dark until root-growth is made. When the roots appear the plant should be placed in a sunny window and will require no further care beyond a daily addition of fresh water.

The variety of Narcissus brought by the Chinese to this country and from here introduced into England, is known as the Grand Emperor. The Chinese bulbs are exceedingly vigorous. They are nearly double the size of those of other varieties of this species of Narcissus, and when grown in water sometimes throw up leaves and flower-stems three feet in height. The Chinese Narcissus is an interesting and attractive house plant. Our illustration above is from a photograph of a plant grown near Boston.

Annuals for Cut Flowers.

ANNUALS suitable for cut flowers are also the most suitable for garden decoration. They should be ready growers and free bloomers, and have bright, showy or fragrant flowers, with stiff stems, and they should last well when cut. And we should grow enough to enable us to have large clusters of a kind rather than a few blooms only of each. While Gaillardias and French Marigolds bloom all summer long, Asters and Mignonette last but a few weeks, and Poppies not many days. To have annuals, therefore, in good condition all summer long, we must make two or more sowings of many kinds. I make repeated sowings of Asters, Mignonette, Phlox, Candytuft and the like, not only to succeed themselves, but also to succeed Hollyhocks, Canterbury Bells, Veronicas and other plants that bloom before midsummer, and are then cut over. And as many of the spring-sown annuals, Zinnias and African Marigolds, for instance, become disheveled before they have quite finished blooming, I never hesitate to clear them away and replace with fresh plants. This necessitates keeping up a reserve stock, which I always do, and in this way have as fine Zinnias, Eldorado Marigolds, Scabious, Salvias and some other annuals, until frost overtakes them, in October, as in July. In order to have good flowers we must grow them in good ground.

We have a great variety of uses for cut flowers. Cannas, African Marigolds, miniature Sunflowers, large Poppies and Zinnias appear to good advantage in large bunches in roomy halls, and if cut with long leafy stems so much the better. For parlor and dining-room tables and brackets we should use the most beautiful flowers, and such as are pleasantly, but not strongly, fragrant. A mixture of many kinds of flowers together in one vase should be avoided.

In addition to the annuals that are most desirable for cut flowers we have a large assortment well fitted for garden decoration, and from which, too, we may cull many a bouquet; for instance, Sweet Alyssum, Schizanthus, Clarkia, Browallia, Mimulus, Godetia, Cornflowers and the like.

The following are all worth sowing for cut flowers:

China Asters.—Truffaut's Improved Pæonia Perfection, Victoria, Crown and Reid's Quilled are capital. By sowing in March, the end of April and the first of June we can have Asters from July till October. Crimson, rose and white are the most desirable.

Candytuft.—Rose and white are the most desirable colors. Sweet-scented, Spiral and Dwarf Hybrid White are the best summer varieties; and *Gibraltarica* is preferred for wintering over in frames.

Cannas.—If sown in March in the green-house, and planted out in May, these should bloom in September.

Single Dahlias.—These grow readily from seed and seedlings four to five months old bloom freely.

Drummond Phlox.—The *grandiflora* section is best. Sow now or in April and again early in June.

Gaillardias.—The annuals, as *G. picta*, and its double variety, *Lorenzia* and *G. amblyodon*, bloom abundantly from June till October, but with age the plants get sprawly, hence the necessity of a successional sowing in May. The perennial *G. aristata* and its *grandiflora* and *maxima* forms also bloom well as annuals.

Larkspur.—Although showy, the annuals are not good enough for cut flowers, but some of the perennial species, notably *Delphinium grandiflorum*, bright and beautiful, are very free flowering when treated as annuals.

Marigolds.—Of the English, Meteor is good in early summer and fall; and of African, the Eldorado strain is unsurpassed. Among French Marigolds the double striped are best, still many prefer the brown or mahogany color.

Mignonette.—Miles' Spiral is one of the best. Sow early and in good ground.

Nasturtiums.—These are desirable on account of their brightness and lasting qualities. Lobb's varieties are better than either the common tall or dwarf annuals.

Pansies.—The Trimardeau gives us the largest flowers. Sow in June for fall flowers, and in August for spring use.

Petunias.—Bunches of double Petunias are quite pretty, and last well. They grow freely from seed, and bloom when about three months old, but we cannot reasonably expect more than twenty-five per cent. to come double.

Poppies, especially the double sorts, last in good condition for two or three days when cut before they are fully open. Sow broadcast about the end of March or first of April.

Scarlet Salvia.—This can be treated as an annual sown in February in-doors and in May out-doors. The flowers last only for a day or two.

Scabious.—The large-flowered section and the very dark plum-purple and white varieties are best, and they bloom all summer long.

Stocks.—The large-flowered ten-week Stocks, scarlet and white, are the best, and it is better to make repeated sowings than to depend upon the Intermediate Stocks for a supply in fall.

Sweet Peas.—Sow in rich soil just as soon as the frost is out of the ground. The first sowings are always good; sometimes the successional sowings will not bloom at all.

Sunflowers.—The "New Miniature" (which is *Helianthus cucumerifolius* pure and simple) is best. The flowers are small, bright golden yellow, with dark centres, and have none of the coarse appearance peculiar to the ordinary Sunflowers seen in gardens.

Verbenas.—The Mammoth strain is best. Sow early, say in February or March, and plant out in May in rich, moist ground. Verbenas will not thrive in hot, dry, poor land.

Vincas.—The pure white variety, and the white, with red eye, are best. Sow early and plant out in late May in a warm, sunny exposure.

Zinnias.—The new one, *grandiflora plenissima*, gives the largest flowers, but the dwarf, double white, yellow and scarlet give the most satisfactory results. Never buy mixed seed, as it not only contains much poor stuff, but many "washy" colors.

Wm. Falconer.

Hepatica and Blood-root.

AMONG the flowers which vie with each other in being the first to welcome April, the Trailing Arbutus is, at the East, as early as any. Even now, however, in early March, the blue-eyed Hepatica is opening in our garden, to which we transplanted it from the woods. It always succeeds in cultivation; but to see it in its beauty one must go to the forest. No flower has a more decided personality—whether its face is seen peeping from among the dead leaves, from the base of some rock, or the brow of some mossy boulder. There are those who maintain that it has no odor. But really it exhales a faint, but exquisite, fragrance.

The Hepatica is a near relative of the Wood Anemone. Indeed botanists now call it *Anemone Hepatica*. Like its delicate cousin, it is apetalous. Below the calyx, at a greater or less distance in particular individuals, is a whorl of three ovate and soft, silky bracts. Beginners in botany mistake these, and naturally, for the calyx. The sepals are quite indefinite in number, as are the stamens and pistils. Its three-lobed, glossy green leaves add much to its charm, and their shape suggested the name of Liverwort.

Another early April flower, equally easy to transplant and to cultivate, is the pretty Blood-root (*Sanguinaria Canadensis*). It belongs to the Poppy family, and its pure white and very deciduous flowers come up enfolded by a leaf. Later on, this leaf expands to a great size, and is itself highly ornamental. One has to be up with the lark to catch its two fugacious sepals.

The Hepatica loves rocky, wooded hillsides, while the Blood-root seeks the banks of streams. Yet both will thrive under wholly different surroundings in a city garden. This leads me to say that many of our wild plants can be cultivated, and with proper care they will increase in size and beauty. Among the spring flowers we have tried are Bluets (*Houstonia carulea*), the yellow Violet (*Viola pubescens*), the wild Columbine (*Aquilegia Canadensis*), the Indian Turnip (*Arisæma tryphillum*), and the Dutchman's Breeches (*Dicentra Cucullaria*). All these, and many more, deserve a place in the flower garden.

Providence, R. I.

Wm. Whitman Bailey.

The Propagation of Magnolias.

WHEN the Magnolias are to be propagated by seed it should be separated from the pod as soon as ripe, macerated in water for a week or more, and then, after a thorough washing in clean water, it should be sown, while still moist, in pots or boxes filled with light, sandy and well-drained soil. These should be kept in a cool house until January, when they may have a temperature of 50° at night and 10° or 15° higher during the day. If the soil is kept moist, but not wet, the seed will usually germinate in five or six weeks, when the young plants can be removed to small pots or boxes. If shifted on from small pots to larger ones during the summer, and grown in a close, moist atmosphere, many of them will be established and fit to graft by autumn. If not sown in the green-house, the seed, after being cleaned, should be put in boxes with sand in alternate layers and placed in a frame or cellar where

it will not freeze, until about the first of May in this latitude, when, as soon as the ground becomes warm, it may be sown out-of-doors. If the seed is not washed clean as soon as possible after gathering, it quickly becomes rancid, and will not germinate readily; but when thoroughly cleaned and mixed with damp sand it will keep for a long time. I have sown the seed without washing, and the pulp in rotting soured the soil and a fungus appeared in it, so that the plants had to be moved into fresh soil to save them.

When the Magnolias are propagated by grafting, the stocks should be well established in pots the year before and plunged in a frame or other sheltered place and cared for during the summer. When cold weather approaches, the pots should be removed, before they freeze, to a pit or frame where they can be protected until used. They can be grafted successfully from the middle of January to the middle of March either by side or cleft-grafting under double frames—that is, under a box frame in the green-house. They prefer a slight bottom heat to start the roots into working condition. The frame should be kept close for a few days, or weeks, during bright weather, but air may be given when the house is closed and on cloudy days. A slight syringing once or twice a day in bright weather will be beneficial. It is usually from three to five weeks before grafts can be considered established, although in from seven to ten days an estimate can be made of what percentage has "taken." Magnolias can also be grafted from half ripened wood from July to September, and they can be budded during August or September. They are usually grafted on stock of *M. acuminata* and *M. Umbrella*; some preferring the latter because of its abundant fibrous roots and the ease with which it can be transplanted. I prefer, however, *M. acuminata*, because the other species suckers, and unless great care is taken these shoots will kill out the graft in the young stock.

Magnolias can also be increased by layering; in fact, until within a few years this was the favorite method of propagation, and few gardeners knew how to graft them. Layering is a simple operation, and can be performed in spring or summer. A small trench is dug a little way from the plant, and into this branches are bent down and held firmly with hooked pegs. The ends are then turned up, the young branches are tongued under an eye and the trench is filled up with good loam. In hot, dry weather, water should be given occasionally. If layered early some of them will root the first season, although many of the Magnolias will not root until the second year. As soon as rooting takes place, the branch should be separated from the old plant, pruned into shape and transplanted into good soil in the nursery.

Jamaica Plain, Mass.

Jackson Dawson.

Rules for Planting Wind-breaks.

THE influence of the wind-break is local and almost entirely mechanical. It prevents the fierce sweep of winds over the surface of the ground, and therefore tends to diminish evaporation from the soil and from plants, especially in cold weather, and to lessen the mechanical injury to trees and bush-fruits. It is apparent to all good observers, however, that wind-breaks are sometimes injurious. Therefore there must be certain rules to govern their planting. The most important of these rules, for Michigan especially, may be briefly stated:

1. *The wind-break should not obstruct atmospheric drainage.* Cold air is heavier than warm air, and it therefore settles into the lower areas. Elevated areas are consequently warmer than low ones in still weather. Inasmuch as these high lands are more wind-swept than others, it has become a common impression that the wind itself is in some manner a protection to fruit plantations, whereas the protection really comes from atmospheric drainage. The wind-break upon most of the elevated areas, therefore, should be open enough to allow of the free drainage of air. In such localities a tight wall of evergreens is apt to be positively injurious. Deciduous trees, with perhaps a sparse admixture of evergreens, make the better wind-breaks for such places. It should be borne in mind that the object is not to stop the wind, but rather to break its force, to check it. Breakwaters are often made of a network of naked spiles rather than a solid wall.

In many interior localities a dense wind-break on the north and west excites an early growth in tender fruits, thereby increasing danger from late spring frosts. Hence:

2. *The wind-break should never be dense enough to force the buds on fruit trees, in those localities which are subject to late spring frosts.* It is evident, therefore, that Spruces

and other evergreens should be planted sparingly in such places, and that deciduous trees, which do not come early into leaf, should be chosen.

One of the most disastrous effects of winds in the orchard, and especially in small fruit plantations, is the sweeping of the surface of the ground, causing excessive evaporation, carrying off the snow and thereby exposing the roots and crowns of the plants to danger. Therefore:

3. *As a rule, in localities where atmospheric drainage will not be seriously checked, the wind-break should have a comparatively dense bottom, formed by undergrowth or low-branching trees.*

All crops closely adjoining the wind-break suffer from lack of moisture and food supply, and many small plants, as bush-fruits and nursery stock, are broken by the accumulating snow. Hence:

4. *So far as practicable, the wind-break should be planted at a distance of six rods or more from the fruit plantation.*

In our severe climate only the most hardy and vigorous trees should be planted; or, in other words:

5. *Native trees and shrubs are preferable for wind-breaks.* Of exotic trees, only the Norway Spruce and Apple are desirable for wind-breaks in Michigan. L. H. Bailey.

The Forest.

The Forests of Vancouver Island.

VANCOUVER ISLAND is situated between the parallels of 48° and 51° N. lat. and between 123° and 128° W. long. It is about 240 miles in length and from 40 to 70 in breadth and contains about 14,000 square miles. With the exception of the southern part and a few settlements at Nanaimo and Comox, the whole island is still covered by heavy forest.

Through the centre of the island runs a ridge of mountainous country of varying width, which, commencing with Donald Peak at Metchosin, runs north-westerly, and, constantly increasing in altitude, culminates in Mount Arrowsmith, about 100 miles from Victoria. This mountain is 5,976 feet high, but to the north numerous peaks rise much higher, ranging from 6,000 to 8,000 feet in height. Lying between the mountain chains, or at the base of the single mountains, are numerous lakes of clear water, which are frequently united by connecting streams and discharged into the sea by rivers of no great size.

It will thus be seen that but a small portion of the surface of the island is level; indeed, it is for the most part so elevated that it must be called mountainous rather than hilly. Owing to the position of the island, in regard to the Pacific, the low grounds seem to have just as damp an atmosphere as the more elevated parts, and a wet, cloudy winter is succeeded by a cloudless, though not atmospherically dry, summer. These conditions will account for the remarkable growth of timber on the island and the appearance of certain trees north of their expected range. The forest ought, therefore, to be composed chiefly of mountain species, and this is the fact, as the hardwood trees of the low or coast districts are of little account in the general distribution.

The Oak (*Quercus Garryana*) occupies more superficial area than all the other deciduous trees together. It is abundant in all the district around Victoria, seldom growing tall and straight like the eastern Oaks, but appearing more like the trees in English parks. Usually the large trees grow singly amongst the rocks, and their gnarled trunks and wide spreading limbs appear out of place in America. North of Victoria it becomes scarce and at last ceases to grow at Comox, 140 miles to the north.

Two other trees claim particular notice. These are the Madrona (*Arbutus Menziesii*) and the Flowering Dogwood (*Cornus Nuttallii*). The former, with its large laurel-like evergreen leaves and reddish bark, would claim attention anywhere, but to find it a stately forest tree north of the 49th parallel is a remarkable fact. On all the islands in the Gulf of Georgia, and on all the exposed points of

the east coast, it is quite common; but on the gravel which occurs between the coast and the base of the mountains, it is frequent, and even on the west coast as far north as Alberni. Nowhere on the island does the Dog Wood come to greater perfection than around Nanaimo, and here, in the middle of May, the borders of the woods are white with the broad involucre of the cymes of inconspicuous flowers. Trees forty feet high are not uncommon, with trunks from six to twelve inches in diameter.

By far the finest deciduous leaved tree on the island is the Broad Leaved Maple (*Acer macrophyllum*). In the early spring, before the leaves are fully developed, it produces racemes of light yellow flowers over six inches long, which are pendant and add much to the beauty of the tree, as they hang between the young leaves and give the whole tree a superb appearance. Later in the season the broad leaves cover up the fruit and one is almost tempted to believe that he looks upon a denizen of the tropics. Bordering ponds and lakelets, and forming thickets so dense that they are almost impenetrable, are three small trees. These are the Wild Crab (*Pirus rivularis*), Wild Cherry (*Prunus mollis*) and "Barberry" (*Rhamnus Purshiana*). The latter, named "Barberry" by the settlers, is used medicinally and is widely distributed, being found far to the north.

Poplars, Alders and Willows are of frequent occurrence, but in no place do they become so abundant as to monopolize much surface. Small groves of Balsam Poplar (*Populus trichocarpa*) are found in low spots by the mouths of rivers, and the trees attain a large size and are tall and straight, but none of the other species, except one species of Alder (*Alnus rubra*), can be considered of value.

The various species of Conifers constitute the true forests of Vancouver Island, and to these we will now turn our attention. They divide themselves almost insensibly into two groups—one of the coast or lower levels and the other of the mountains—but some species pass from the plain to the mountain, while others are restricted to the coast or to the mountain summit.

The coast species, which are never found on the mountains, are *Abies grandis* and *Picea Menziesii*, together with the Yew (*Taxus brevifolia*) and the Red Cedar (*Juniperus Virginiana*). Owing to the peculiar distribution of the last species, it has been mistaken for the more southern *Juniperus occidentalis*, but all doubt regarding it has been removed the past summer. On the shores of Cameron and Horne lakes, near the centre of the island, fine trees line the shore and overhang the water, but they are never seen in the forest. The Yew is not uncommon in many places near Victoria, but it is sparingly distributed and seldom a marked feature of the forest growths.

The Fir (*Abies grandis*) is a noble tree and is a most striking object in the river valleys near the coast on both sides of the island. In company with the Sitka Spruce it forms many beautiful groves in the low country between Nanaimo and Comox. Beyond the latter point the Spruce becomes a more characteristic feature and even rivals the stately Douglas Fir itself. Around Alberni and in the valleys of the Somas River and the lakes connected with it these trees attain very great dimensions and often tower up 200 feet, with a beautiful pyramidal head of short, light green branches.

Pinus contorta is either represented by tree forms or has a most peculiar habit. At one time it is found clinging to the rocks close to the sea, at another growing in a bog in company with *Kalmia* and *Ledum*, and at Qualicum it forms a strip of forest nearly five miles wide that intervenes between the sea and the base of the mountains. Here the soil is chiefly gravel, and the tree looks very much like its cousin of the Rocky Mountains, *Pinus Murrayana*, and certainly grows under the same conditions, except that of altitude.

Ottawa, Canada.

John Macoun.

Propagation of Conifers from Seeds in the Open Air.

UNTIL about thirty-five years ago no one had succeeded in growing Conifers from seed in America, except under glass. Consequently our American nurseries were stocked with imported seedlings of the foreign kinds and with native seedlings collected in the forests.

I had seen large quantities grown in the full sunlight in the North of England as easily as Carrots and with no shelter, and therefore began by investing \$70 in seeds of the common European kinds and in several hundredweight of seeds of the native kinds collected for me in the Green Mountains. I sowed them on four acres; they germinated finely, and were a beautiful sight. I had about a week of unalloyed pleasure, except for an hour now and then consumed in wondering where a market could be found for such a large amount of stock. This problem, however, was soon solved. A bright day, a gathering thunder-shower, a heavy rain and the sudden reappearance of the scorching sun at about 2 P. M.! I went to examine my seedlings, and found them all down flat, damped off or scorched off, except a part of those latest in starting that were just breaking ground. I immediately sent for 4,000 feet of lumber, and this, with the help of an adjoining rail fence, was soon worked up into a shelter; but at the end of the season not one seedling was left.

I should gladly have given up and made no further experiments, but I had announced that success was coming, and it was too late to retreat. So I took to the woods and studied the surroundings of the seedlings in the forests. It was plain that Nature had a decided advantage over me, as it cost her nothing for seeds, and she apparently did not raise more than one or two trees from a million of them. Finally, after the next winter was nearly over, and I had secured a large stock of seed for spring sowing, I bethought me of several hundred gunny bags that had lain for years unclaimed in a steamboat warehouse. Securing them, we sowed our seed in four-foot beds, stretched the gunny bags tightly on the frames one foot from the ground, and succeeded in raising a fair crop, as the bags let the rain through evenly.

It was soon evident that the more open the sacking was, the less the plants damped off, showing that they required more sunlight. We then built frames of lath, leaving spaces between. Experiments were made to ascertain the degree of sunlight most favorable to the seedlings, and it was found that we succeeded best when one-inch spaces were left between the laths, with the frames they rested on six inches high. We followed this lath-shading for several years, until we found it almost impossible to get the quantity of lath we needed, as at the lumber mills they were only prepared to sell a certain proportion of lath with a cargo of lumber.

Finally, over twenty years ago, we adopted our present mode of shading with posts, poles and brush. Not that we considered it cheaper or better than the lath screens, but the material can be more readily obtained. Rows of posts seven feet high are set ten feet apart and eight feet distant in the rows. Fence-boards six or eight inches wide and sixteen feet long are nailed upon these at the top. Slender poles are laid across, and on these are placed branches of trees with the leaves on them. The beds are four feet wide and are laid out so that the row of posts runs up the middle of each alternate bed. If the soil is tenacious we throw it up in ridges the previous fall. The beds are raked very fine, the seeds sown dry in spring, broadcast, and raked in—the fine seeds lightly, the larger seeds more deeply. We cannot protect the seeds from birds with the brush shade as conveniently as with lath screens, but must cover them with brush or straw, or they will be scratched out.

The seeds are sown thickly, the European Larch more thickly than the others, as the imperfect seeds cannot be separated, for they are merchantable when one-third to one-half are "blind" seeds. From the time the seedlings appear above ground until they begin their second growth, they are liable to "damp off" during murky weather, in which case the screens must be taken off; but great care must be taken to have them replaced without loss of time when the sun appears. We formerly used dry sand, sprinkled over the beds, to check the damping off, but could perceive little or no benefit from it. "Rich soil encourages damping off." The beds must be thoroughly hand-weeded during the summer. Late in autumn the beds should be covered with forest leaves, with a light covering of straw or brush to prevent their being blown off. Larches are usually thinned out of the beds at one year old; other Conifers at two years old.

Robert Douglas.

Recent Publications.

Review of Forest Administration in British India for the year 1885-86, by B. Ribbentrop, Acting Inspector-General, Indian Forest Department. Simla, 1887. *Report of the Forest Department, Madras Presidency, for the year 1885-86*, by Lt.-Col. I. Cambeld Walker. Madras, 1887.

These two Reports have only just reached us. They contain the record of the work done in the Indian forests, with its financial results, for the period which they cover. The Indian Forest Department is less than a quarter of a century old. Its organization by Dr. Brandis in the face of serious native opposition, great natural difficulties, and without, at the start, a properly trained staff of assistants, is one of the greatest administrative triumphs of recent times.

The Indian forests, previous to the establishment of the Forest Department, yielded nothing to the Government. In the years covered by these Reports the net profit derived from working them systematically was over three and one-half million dollars, the operating expenses amounting to sixty-three per cent. of the gross revenue. The net receipts of the Department have increased steadily for a number of years; and they will, it seems pretty safe to predict, continue to increase as long as it is administered in the same able manner.

The history of forest administration in India might be studied with advantage by the Secretary of the Interior and members of Congress of the United States. The forests which grow upon our national domain produce no income. The land upon which they stand is sold sometimes at a mere nominal price, and while the Government is waiting for customers the forests themselves are robbed of their best timber, burned, pastured, devastated and destroyed.

Recent Plant Portraits.

Botanical Magazine, January, *Phormium Hookeri*, t. 6973; a third species of the New Zealand Flax; discovered several years ago on the Waitangi River "growing pendulous from almost perpendicular rocks, in great abundance"; and now cultivated in southern England, where it flowers and ripens its seed very freely.

Ceratophylla triloba, t. 6974; a tall pubescent herb with the habit of a Foxglove, native of Natal and closely allied to the common cultivated Indian *Sesamum Indicum*, L.

Thunbergia affinis, t. 6975; a tall shrub, a native of Zanzibar, with handsome dark blue flowers, similar, although far more beautiful, than those of the old *T. erecta*.

Prunus Jacquemontii, t. 6976; a dwarf, compact, hardy shrub, with delicate pink flowers; common in the north-western Himalayas and extending into Tibet and Afghanistan.

Masdevallia Chestertoni, t. 6977; a rather small flowered, and horticulturally, not very attractive species of this immense genus; a native of New Grenada.

Periodical Literature.

THE *Art Amateur* for January, 1888, contains a pleasant and suggestive paper on Japanese modes of arranging cut flowers, leaves and branches. The matter is one which the Japanese only have considered from an artistic point of view, but which certainly ought to be so considered by all who profess to care for flowers or for beauty in the abstract. Therefore this article is welcome, although it gives but a hint of the great stress which the educational systems of Japan lay upon the art of floral arrangement, and explains, with the aid of illustrations, only one or two of the effects they consider desirable, and one or two of the skillful and ingenious devices in which the student is instructed.

Cassell's Family Magazine will print during the year a series of popular articles treating of the garden and the work to be done in it during each successive month. "The Garden in January" and "The Garden in February" have already appeared; and while they naturally have a greater practical value for the English than for the American reader, they are by no means devoid of interest even for the latter.

Longman's Magazine for February, 1888, contains a brightly written chapter on "Orchids," by Frederick Boyle, a man of letters by profession, but an enthusiastic, and, from his own account, a successful horticulturist in his leisure hours. It is accompanied by none of the charming illustrations which have been given with articles on the same subject in more

than one of our own popular magazines, and its purpose is not, like theirs, descriptive. Its purpose is simply to prove to those who are already well aware of the beauty of Orchids, that it is by no means so difficult a task as amateurs generally suppose, to grow many species to perfection by the aid of the simplest arrangements and with the expenditure of very little time or pains.

In *McMillan's Magazine* for January, 1888, Forestry is discussed by Mr. George Cadell, formerly connected with the Indian Forestry Department. Some time ago the House of Commons for the third time appointed a Commission to inquire "Whether by the establishment of a forest school, or otherwise, our waste lands could be made more remunerative." At the time when Mr. Cadell wrote, this Commission had reported to Parliament, but no action had yet been taken on its report. Meanwhile he discusses the condition of the Crown forests in England, briefly explains the management of those in India, refers to the great benefits which France and Switzerland have received from a judicious system of control, and points out as a subject for national mortification that both at the Cape and in Cyprus, England has been obliged to depend upon the services of foreign experts in Forestry.

Flower Market.

NEW YORK, *March 16th, 1888.*

The quality of cut flowers is much better this week than last, notwithstanding a large quantity has been held on snow-bound trains. Hybrid Roses are very handsome, but have declined somewhat, those selected of favorite sorts bringing only 60 to 75 cts. each. There was no demand for flowers during the storm of the early week, but trade has been picking up since and is brisk to-day. There is an over supply of La France Roses, the very choicest bringing but \$2.50 a dozen. The finest Puritans sell for 50 cts. Ulrich Brünner sells rapidly at 75 cts. a flower. Popular varieties of Tea Roses, such as Papa Gontier, bring \$1.00 a dozen. Selected buds of Bride or Cornelia Cook cost \$3.00 a dozen. Tulips, Lilies-of-the-Valley and Roman Hyacinths are 75 cts. a dozen. Dutch Hyacinths are in large variety and in lively demand at 15 cts. a spike; Mignonette from 50 cts. to \$1.50 a dozen spikes; Carnations from 35 cts. to 50 cts. a dozen, the latter price being for favorite kinds, such as Buttercup and Grace Wilder. Violets continue firm at \$1.00 a hundred for the average quality and \$1.50 for those of extra beauty and fragrance. Smilax costs 30 cts. a yard.

PHILADELPHIA, *March 16th.*

The severe snow storm prevented growers from shipping flowers to the city in the early part of the week. It also interfered with the demand and prices have varied little since last quotations. The most notable Rose now in market is Madame Gabriel Luizet. Finer flowers of this variety were never before seen here; they are selling from 75 cts. to \$1.50 each. Mrs. John Laing is also cut in quantity; the latter is the newer, but it can never displace Madame Luizet, excepting, perhaps, for very early work. Puritans are improving in quality, and are in fair demand; it is not a first-class Rose to ship long distances; some of the growers bring it to the city in deep boxes of moss, into which the stems are thrust; this holds them steady and upright and insures safe arrival. Heath is in fair demand at 15 cts. per spray. The kind offered is a variety of *Erica caffra alba*, and is grown near Boston. It is rarely used alone, but is added to boxes of choice flowers, or is arranged with Orchids.

BOSTON, *March 16th.*

There is little change in the cut-flower market. Hybrid Roses and Jacqueminots are if anything more abundant and of still better quality. Both yellow and white Roses are scarce and they are eagerly taken as fast as brought to the city by the growers. Tulips, Lilies-of-the-Valley, and other bulbous flowers are still plentiful. Roman Hyacinths are scarce, but in their stead there is an abundance of the Italian variety, which, although slightly pinkish in color, has the advantage of bearing a larger and stronger flower spike than does the Roman. The supply of Carnations is diminishing, and prices will undoubtedly advance considerably before Easter. A few White Lilies are seen, but they are mostly short stemmed and are of little use excepting for funeral designs. Harris's Lilies and Callas are worth \$3.00 per dozen. Most people in buying Callas now require a few of the leaves with the flowers, which add much to their appearance. Hybrid Roses of extra quality bring from \$6 to \$9 per dozen. Jacqueminots, Mermets and a fair quality of hybrids are \$3.00; Perles, Niphotos and Bon Silene, \$1 per dozen; Lilies-of-the-Valley, Tulips and Narcissus of various kinds average about \$1.00 per dozen. French Marguerites, Mignonette, Forget-me-nots, Carnations and Heliotrope sell for about 50 cts. per dozen sprays; Pansies and Violets 50 cts. per bunch. Among Orchids the most attractive now in season are the Odontoglossums. Nothing more beautiful for a bridal wreath or coronet than a spray of *O. Alexandra*. Perfect sprays are worth from \$2.00 to \$3.00 each.

GARDEN AND FOREST.

The Adirondack Forests in Danger.

THE preservation of the Adirondack forests is a matter of national importance. Their destruction will work injury far beyond the limits of the State of New York. One of the principal commercial rivers of the world depends upon these forests for its existence; their value as a health resort for people from all parts of the United States is incalculable. Their preservation, therefore, is a matter which concerns the whole country.

Never have these forests been threatened with such dangers as now menace them from every side. Railroads are being built or are about to be built into the wilderness in every direction. The promoters of the Schenectady and Ogdensburg Railroad Company propose to build a line this summer directly through the heart of the Adirondacks, to serve as a feeder for the Canadian Pacific and bring that road into direct connection with New York and Boston. The Chateaugay Railroad Company is extending its line into the forest. Last year it had reached the shores of Loon Lake; now it has been carried to Saranac Lake. Its last station is only eight miles from Lake Placid and within six miles of Paul Smith's, upon St. Regis Lake. Adirondack Lodge, one of the wildest and most picturesque spots in the whole region, is now but fifteen miles distant from the railroad. The Northern Adirondack Railroad has penetrated through the forest almost as far south as Paul Smith's. Another road runs from Carthage, in Jefferson County, into the forest region. It has recently been carried to Jayville, in St. Lawrence County, and a further extension is proposed.

The building of railroads through a forest in this country means its extermination. This is particularly true of the Adirondack forest. Its escape from extermination in the past is due to the single fact that the hard woods of which it is principally composed could not be got to market from lack of transportation. If transportation is furnished it is mere-

ly a question of time when every tree will be consumed in the saw-mill, the paper factory and the charcoal furnace. Railroads will increase, too, the number of fires in the forest and thus hasten its extermination.

There is but one way to save what now remains of the Adirondack forests. The enactment of a law which shall prohibit the location of any railroad under any circumstances upon the State lands which are widely scattered through the entire region will prevent its ruin. No other measure less sweeping in its restrictions can accomplish this. There is a Board of Forest Commissioners in this State. It is the duty of these Commissioners to devise measures for the protection of the State forests and to see that these laws are put into execution. It is their duty to enlighten the people of the State upon the condition of the State forests and the dangers which threaten them. It is their duty under the law to provide instruction for the people of New York in all matters relating to forests and forestry, and to arouse them to the importance of a full comprehension of these subjects.

Have these Commissioners performed these duties?

Have they introduced any bill looking to restraining the building of railroads through the forests?

Have they even tried to rouse the attention of the public to this matter?

Do the reports which they publish from time to time, at no small expense to the people of this State, contain any valuable or accurate information in regard to the forests or to methods of forest preservation?

The only activity displayed by the Commission, so far as the public is informed, is manifested in their attempt to secure from the present Legislature the passage of a bill authorizing them to lease to "individuals or clubs for pleasure resorts or camping purposes," portions of the public domain for periods not exceeding five years' duration. This authority should not be given to the Commission. It would open the door to corruption and would threaten the forests with new dangers. Thousands of acres of Adirondack forests have already perished at the hands of hunters and camping parties. Their carelessness in setting fires and their recklessness in barking and destroying trees, are only too well known. It will be impossible to protect the State forests if the Commissioners are allowed this privilege.

The actual condition of the Adirondack forests and the doings of the Forest Commissioners during the three years they have held office need investigation. The public cannot afford indifference in this matter. Too much is at stake. The commercial and sanatory interests involved in the protection of these forests are too great to allow them to remain the prey of designing politicians and speculators.

A few years ago the concerted action of the press of this State roused public attention to the importance of preserving the Adirondack forests and the rivers which flow from them, and made the passage of forest laws and the appointment of a Forest Commission possible. The laws were rendered inadequate, and the people were cheated by politicians and speculators, who secured the appointment of an improper Commission. The result has been disastrous, and never in the history of the State has the danger to the forests been so real and imminent as it is to-day. The public must be enlightened and aroused to active interest in the matter; and the concerted and energetic action of the press of the whole country can alone accomplish this.

Horticultural Fashions.

IN the last fifty years there have been a number of horticultural fashions of longer or shorter duration. Just now the cultivation of Orchids chiefly occupies the horticultural world. Such fashions, while they have, perhaps, an unfortunate influence upon the gardening profession, are often otherwise beneficial. This was the case with the craze for Conifers which prevailed in England forty or fifty

years ago. It had the effect of driving out of cultivation a host of deciduous trees and shrubs of which gardeners who were learning their profession at that period never acquired any knowledge; but, on the other hand, it stimulated botanical exploration and vastly increased our knowledge of one of the most important and valuable families of plants. Had it not been the fashion to plant Conifers in England, it is probable that the Floras of the Californian Sierras, of the Andes, of the mountains of Mexico and Japan, of India and the Caucasus, would not be as well known as they are to-day. Other horticultural fashions have not been as productive of good. The fashion, for example, of massing together large numbers of a few varieties of tropical or semi-tropical flowering or bright-foliaged plants, known as the "bedding-out system," has little to recommend it from the point of view of the increase of human knowledge. And certainly no horticultural invention has done so much to limit the intelligence and practical skill of gardeners. Not much better has been the extravagant fashion of filling green-houses with what are known as fine-foliaged plants—inhabitants of tropical swamps. These plants rarely have conspicuous flowers, and their only interest is found in the curious shapes and markings of their leaves. They have not the graceful habit of many Palms; they cannot bear the temperature of ordinary conservatories and living-rooms, and can only be enjoyed in the reeking atmosphere of close, damp stoves. But no plants are more easily cultivated, and it is not surprising that they are favorites with gardeners trained in the "bedding-out" school—of which the taste for them is the natural outcome—and that they have driven out a multitude of beautiful flowering plants which it taxed the best gardening skill to bring to perfection.

The fashion for cultivating Orchids is not new. A few species were introduced into English gardens in the second half of the last century, and Orchids have been cultivated in the United States during the past seventy years. The taste for them shows no sign of flagging, but, on the contrary, has steadily increased, both in this country and in Europe, during the last half-century, and has never been so strong or so general as it is to-day. In the United States especially great progress has been made in the cultivation of these plants in recent years. They now form the principal attraction at many of our flower-shows, and two or three American collections rank with the finest in the world; and while as a nation we are not yet quite as crazy about Orchids as the English, the crowds which surrounded the tables at an exhibition of Orchids recently held in this city, and the high prices which these flowers bring in our markets, pretty clearly indicate the effect of fashion in horticulture.

The Orchid fashion has certainly much more to recommend it than many fashions of a similar kind. The love for cultivating these plants has done as much as any one single agency to make known the vegetation of the tropical parts of the world; their flowers, as Darwin taught us, are among the most wonderful of all the creations of Nature in their adaptation of means to ends; and many of them possess wonderful beauty of color and form. It is a question whether the most beautiful Orchid flower ever produced can equal the beauty and grace of the Poet's Narcissus, which was a favorite garden flower centuries before the first Orchid was cultivated and which will be a favorite centuries after three-quarters of the Orchids which collectors now hold so dear will be found only in their native haunts or in ancient volumes of the *Botanical Magazine*. Yet among the mass of Orchids now cultivated because they are new, or rare, or expensive, or odd, are many of very great beauty, and these will continue to be cultivated as long as the taste for horticulture lives. And the cultivation of such Orchids will increase in this country as they become better known and as people appreciate how easily they may be grown. The belief is still general here that Orchids are difficult to cultivate and can be made to flourish only in great heat. On the contrary, few plants are more easily grown if attention is given to a few of their simple requirements, and

many of the finest varieties will thrive only in the low temperature of a cool green-house. Indeed, many Orchids will grow, as an English writer recently said of *Phalenopsis*, "with the calm complacency of the cabbage." There is, too, a fascination in cultivating these plants which increases with experience. But it must not be forgotten that any fashion, however solid the merits upon which it is founded, may easily be carried too far, and that there is great danger that this growing love of Orchids may lead to the neglect of other and equally interesting and beautiful plants. A one-sided development is as dangerous in horticulture as in other human pursuits.

Hardy Shrubs.

THE true value of hardy deciduous shrubs is not yet appreciated in this country. The climate of the Eastern and Northern States is peculiarly suited to develop, in the highest degree, the beauty of many flowering shrubs and trees. Our intensely hot summers, long, dry autumns, and cold winters ripen the flowering-wood and give results which are quite unknown in countries where the changes of temperature are less marked.

The development of American gardening has suffered greatly during the last fifty years from attempts to imitate English gardens in their composition. In our efforts to cultivate the Conifers and broad-leaved evergreens which thrive in England, we have overlooked the fact that our climate is not suited, save in exceptional instances, to bring out their beauty, and that it is a climate particularly adapted to deciduous plants. Thoughtful students of the relations between cultivated plants and climate now begin to realize that if we are ever to have in America a distinctive school of gardening, it must be based upon a comprehensive use of hardy deciduous shrubs.

These have other qualifications, in addition to their abundant flowers, to commend them to more general use. They are easily and cheaply raised. They are long-lived and increase in beauty from year to year. Their size adapts them to the small gardens which must always be more common than large ones in this country. Many deciduous shrubs and small trees also have the charm of brilliant autumnal foliage and conspicuous persistent fruits. The variety of such plants which can be made to flourish in our Eastern and Northern gardens is enormous. Few persons yet realize what a shrub-garden in Eastern America might be made. In such a garden could be gathered the shrubs of Europe and their innumerable varieties, the result of centuries of careful selection and cultivation—for European shrubs flourish here although European trees do not; and those of northern China and Japan, countries rich in plants of this description, which have already given us some of the most beautiful ornaments of our gardens—the Forsythias, Deutzias and Weigelas, the Flowering Quince, the Crabs and the finest of the Spiræas.

Such foreign shrubs—when shrubs are used at all—now beautify our gardens, and American species, although not less beautiful and better suited to our climate, are almost entirely neglected. The Flora of North America is rich in shrubs and shrub-like trees the more general cultivation of which cannot be too strongly urged. So numerous are they and so varied in character and beauty, that gardens planted with them alone—without any admixture of exotic material—might be made interesting and charming at every season of the year. What small trees excel the little known or appreciated American Thorns, beautiful alike in their spring flowers and their autumnal foliage and fruit, or the Shadbush and the Judas Tree when they enliven in early spring the borders of the leafless forest—the one with white bloom, the other with glowing pink? No tree is more striking than the Flowering Dogwood when its broad white bracts expand, or more splendid in its autumn color. And these would be followed by the Fringe Tree, by the Rattlebox with its branches covered in early

summer with myriads of drooping white bells, and by the Sour-wood with pendulous racemes of Lily-of-the-Valley-like flowers and with scarlet leaves in autumn.

And with these and many other native flowering trees, might be grouped an almost endless variety of shrubs blooming in succession from earliest spring to late summer, and brilliant with autumn tints or conspicuous fruit;—the delicate *Rhodora* which tinges our northern swamps with pink in early spring; the gorgeous orange-colored *Azalea* which flames on the slopes of many southern mountains; the deliciously fragrant *Calycanthus* and *Clethra*; a host of *Dogwoods* and *Viburnums*, beautiful in flower and fruit; *Blueberries* of many varieties, modest in flower but hardly equalled in grace of habit and richness of October hues; the *Sumachs* and the *Black Alder* which in winter enlivens northern swamps with its scarlet fruit. And in such a garden a collection of native *Roses* would not be the least attractive feature. We have here merely indicated some of the rich material within reach of American gardeners. But the subject will be elaborated in future issues of this Journal, and some of the most valuable and some of the least known American shrubs will be figured and described.

We are glad to publish the letter on landscape gardening which will be found upon another page, for the subject is one about which it is desirable to create discussion. The statement in the first paragraph, that landscape gardening as a fine art means something very different from the mere cultivation of ornamental plants and the designing of isolated minor decorative features, is undeniable. But we cannot agree with our correspondent when he thinks it needful to give the name of "landscape horticulture," or any narrowly distinctive name, to "the industrial art which shapes the ground, plants the trees, makes the walks and drives." The actual manual work of doing such things is, of course, artisans' work—work similar to that which masons and carpenters do for the architect. But to know how such things should be done seems to us an integral part of the equipment of the landscape gardener as an artist. Knowledge of this kind will not make him an artist. But he cannot be a good artist without it any more than an architect can be a good artist without a knowledge of building construction; and, on the other hand, it cannot itself be put to good service unless guided and inspired by artistic impulses, any more than a knowledge of building construction can. These two arts—landscape gardening and architecture—are like one another and unlike the other arts by reason of the fact that they can never be manifestations of the æsthetic instinct in a pure form. Practical considerations must always mingle with and largely limit and control æsthetic considerations when their works are in question. In the preliminary stages of education the acquirement of practical knowledge and the development of æsthetic feeling may seem distinct and different aims. But they should always be fostered together as far as possible; and to divorce them in theoretical expositions of the art of landscape gardening, in its practice, or even in its nomenclature, would be a grave mistake.

Nothing indicates so clearly the rapidly increasing scarcity of the more valuable woods produced by our forests as the gradual substitution for them in the markets of the country of woods which up to a short time ago were considered useless.

The wood of the Cottonwood (*Populus monilifera*) a few years ago had no commercial value whatever in the United States, and was used for fuel only on the plains, where nothing better could be obtained. Improved and stronger machinery, however, has made it possible to saw this wood into lumber in spite of its tough, difficult grain, and there is now a large demand for Cottonwood lumber throughout the West as a substitute for white pine and yellow poplar (*Liriodendron*) for light packing-cases of all

kinds, immense quantities being manufactured at St. Louis and other places. The wood is found to possess the merits of cheapness and of greater lightness than white pine, and it is absolutely free from all odor or taste, valuable qualities in a case where articles of food are to be packed. It is also used for lining refrigerator-cars, and to some extent in the manufacture of cheap furniture.

The Cottonwoods, of which there are several species in the West and South-west, all produce wood very similar in quality, and are among the largest, most common and widely distributed trees along all the rivers west of the Alleghany Mountains. They grow with great rapidity, propagate themselves freely by their light seeds, and are more easily raised from cuttings than almost any other trees. The Cottonwood thrives also in the dry climate of the western plains and prairies better than almost any other tree. There is every prospect, therefore, that our supplies of Cottonwood lumber will not soon become exhausted.

A recent issue of the *Boston Journal* contains the statement that City Forester Doogue of that town had been experimenting with a preparation invented by him for the destruction of Canker-worms, with such success as to determine him to put it to general use on the city Elms. His method is to bore a hole, about three inches deep and an inch and one-half in diameter, in the trunk of the tree, and to insert a mysterious powder, the composition of which is known only to himself. The hole is then plugged up and made perfectly tight with wax. Boring and plugging trees with nostrums is an old and futile remedy; and it seems almost incomprehensible that a man occupying so responsible a position could be guilty of such quackery. The old way of using oil-troughs to stop the ascent of Canker-worms, if systematically carried out, is effectual in destroying them; and they might easily be exterminated if communities would combine in the use of such appliances.

Landscape Gardening.—V.

THERE is still one point which must be noticed as affecting the question how much the landscape artist owes to nature, how much to himself and his fellow-men. When we speak of "natural scenes" we are apt to mean, illogically, all those which have not been modified by the conscious action of art as art. We recognize a park landscape as non-natural; but those rural landscapes in cultivated countries from which the designer of a park gets his best inspirations—these, too, are non-natural. "If in the idea of a natural state," says an old English writer, "we include ground and wood and water, no spot in this island can be said to be in a state of nature. . . . Wherever cultivation has set its foot—wherever the plow and spade have laid fallow the soil—nature is become extinct."

Extinct, of course, is too strong a word if we take it in its full significance. But it is not too strong if we understand it as referring to those things which are most important to the landscape gardener:—the compositions, the broad general pictures, of nature, have become extinct in all thickly settled countries. The effects we see may not be artistic effects—may not have resulted from a conscious effort after beauty; but they are none the less artificial effects. They do not show us what nature wants to do or can do—only what man and nature have chanced to do together. When English artists became dissatisfied with the formal, architectural gardening of the seventeenth century, they fondly imagined that they were learning from nature how to produce those effects of rural freedom, of idyllic repose, of seemingly unstudied beauty, grace and charm, which were their new desire. But, in reality, they were learning from the face of a country which for centuries had been carefully moulded, tended and put to use by man. In some of its parts, of course, the effects of man's presence were comparatively inconspicuous. But of most parts it could be said that for ages not a stream or tree or blade of grass had existed except in answer to his efforts, or, at least, in

consequence of his permission; and it was these parts and not the wilder ones which gave most assistance to the artist. An instinctive love for beauty had doubtless often tried to express itself in the neighborhood of dwellings, absent though the idea of art had been from the mind of their inhabitants; nature herself is so good an artist that even in her bondage she had worked admirably and with more suavity and gentleness than in her free estate; and the mere utilitarian treatment of the land had also accidentally given rise to happily suggestive features. Take, for example, the lawn, which is so essential a feature of almost every artistic design in landscape. It is not true to say, as often has been said, that nature never suggests a lawn. But it is true to say that she did not suggest it to those English gardeners who developed it so beautifully. They must have been inspired by the artificially formed meadow-lands and glades of the England of their time.

But all the semi-natural, semi-artificial beauty of England would not have taught them how to make beautiful parks and gardens had they not been taught as well by their own imagination. What they wanted to create were landscapes which should charm from all points of view and should bear close as well as distant examination; and, moreover, landscapes which might fitly surround the habitations of man and accommodate his very various needs and pleasures. Such landscapes we can no more expect to find in nature—even in cultivated, semi-artificial nature—than landscapes painted upon canvas. That is, while we can imagine a natural spot which would be an appropriate setting for a hunter's lodge or a hermit's cell, we can imagine none which would appropriately encircle a palace, a mansion, or even a modest home for a man with civilized habits and tastes. Every step in civilization is a step away from that wild estate which alone is really nature; and the further away we get from it, the more imagination is needed to bring the elements of existence which nature still supplies into harmony with those which man has developed. The simplest house in the most rustic situation needs, at least, that a path shall be cut to its door; and to do so much as cut a path in the most pleasing possible way needs a certain amount of imagination, of art. How much more, then, is imagination needed in such a task as the laying-out of a great estate where subordinate buildings are to be grouped around the chief one, and all are to be accommodated to the main unalterable natural features of the scene, where a hundred minor natural features are to be harmoniously disposed, where convenient courses for feet and wheels are to be provided in every direction, where gardens and orchards are to be supplied, where water is to be made at once useful and ornamental, and where every plant, whether great or small, must be beautiful at least in the sense of helping the beauty of the general effect? The stronger the desire to make so artificial an aggregate of features look as though nature might have designed it, the more intimate must be the artist's sympathy with the aims and processes of nature and the keener his eye for the special opportunities of the site; but also the stronger must be his imaginative power, the firmer his grasp of the principles and processes of his art.

M. G. van Rensselaer.

Bridge at Leathertor, England.

THIS very ancient bridge spans one of the small streams on Dartmoor, in the south-west of England. Its construction is sufficiently explained by the picture—two land-piers and one stream-pier are connected by long spanning-stones which carry parapets made up of large irregular blocks. It is hardly necessary to point out the degree to which this bridge combines picturesque beauty with durability, or to explain the fitness of such bridges for rural situations in our own country. In the immediate vicinity of a very dignified house so rude and unarchitectural a bridge would perhaps be out of place; and the same is true of those portions of an urban park where formality rules or where architectural works of importance are in view. But in the sequestered, naturally treated portions of

parks, a bridge of this sort would be entirely appropriate; and carrying a road or footway near a country home of modest character or in a village suburb it would be a most charming feature. Naturally we have no wish to suggest that this bridge need be copied either in its special form or in the size and disposition of its stones, although in both these respects it would be an excellent model. It is illustrated merely to show how very simply a stone bridge may be built, and how incomparably better in effect it is than the ugly constructions of iron or the rough assemblages of planks with which in this country we are so familiar. Weather-beaten boulders as old as those in this bridge at Leathertor, and as appropriate for bridge-building, lie by every New England stream, and it would need no high degree of skill to put them to service. But we seem to have thought the bare, straight lines of iron more beautiful than the infinite variety of form and surface and color of our moss-grown stones. It is full time we changed our minds.

After the Great Snow Storm.

I GATHERED pink and white blossoms of the Spring Beauty on the 10th of the present month, and on the 12th they were under the drifting snow of what will pass into history as the great storm of March, 1888.

The wild weather of that day gave me no little concern with regard to the old trees near my house. As a consequence, I twice faced the storm at its height and took brief notes as to the action of the wind upon them. I was curious, too, to know which species was suffering most from loss of branches or general mutilation. The snapping and crashing heard above the wind's roaring suggested universal destruction. Judging from past wind-storms, I looked for the leveling of the fourteen Pines near the house, or at least that the trunks alone would remain standing; but these unaccountably escaped all serious injury and are still the same sorry-looking irregularities they have been for the last twenty years.

It is not a little strange that the long rows of White Pines planted by Joseph Bonaparte in his park near Bordentown, N.J., more than sixty years ago, have escaped serious breakage from wind, encrusting snow and ice-encased twigs—the three causes that have, separately and combinedly, effected the uncrowning and disfiguring of the Pines at home, which are no more exposed and scarcely three miles away. Do not these trees generally require planting in clusters, so as to be self-protecting, or to be intimately associated with other trees? A lone Pine is very pretty and poetical, but hereabouts it is as uncertain as the average white man.

But to return to the forest in the storm. Of a hundred or more large trees, Oaks, Chestnuts, Birches, Gums, Liquidambar, Persimmons, Catalpas, Beeches and Sassafras, occupying some three acres of southward sloping hillside, but one, a large Chestnut, was uprooted, and this was lifted bodily from the ground and carried several feet from where it had stood. The others were twisted; branches were interlocked, and several so shaken and wormed about that the closely wrapping Poison Ivy was detached, an occurrence I should never have dreamed could have taken place. Where branches were broken, they were, as a rule, detached from the trunk of the tree as though seized at their extremities and twisted off. Although the wind remained in one direction, it evidently became a whirlwind among the tree-tops, as shown by the direction of the fall of several large limbs. One large branch of an enormous Beech was broken off, but still holds by long cables of twisted strips of bark, as though the storm had repented and tried to repair the damage by tying it on again.

Of the several species of trees I have mentioned, no two are of like toughness in the texture of their wood, and in this storm the weaker and more brittle kinds did not suffer as much as the tough old Oaks. Nor were the detached branches worm-eaten and so abnormally weak. I was confronted with contradictions whichever way I turned. Associate these with wind having a velocity of fifty-four miles an hour and air full of sand-like snow, and realize how easily one could become bewildered.

In the more exposed upland fields not a tree suffered, the big Sassafras, sixty-two feet in height, not losing even a twig. Stranger still, the scattered Beeches and White Oaks that have retained their withered leaves all winter, hold them still. In short, the home woods suffered very little, and what damage there is occurred where I least expected to find it. Where the exposure was greatest, there every tree successfully weathered one of the severest storms on record. The shrubbery, seedling Oaks and Beeches, puny Cedars and trim little Junipers were bent to the ground and remained prostrate for three or four days. The snow has now melted and all are again erect;

but when I bent some of them to-day, as flatly as did the snow and wind, they cracked and were destroyed. Was it that the gradual pressure of the snow prevented the disaster that my more sudden bending caused?

While I rejoiced at having my woodland still intact, there was one aggravating feature about it all. I anticipated a harvest of dead limbs for my andirons; but they too withstood the tempest. To-day they looked down at me with a tantalizing "no you don't" expression that robbed me of half the pleasure of seeing Black Alder laden with its crimson berries resting upon a dazzling drift of unstained snow.

Near Trenton, New Jersey.

Foreign Correspondence.

The Kew Arboretum—II.

BEFORE giving details of some of the most important collections and of the most remarkable specimens here, it may be as well to say a few words regarding the general aspect and position of the Kew establishment.

stands the Kew Observatory—we pass through the collections of Cypresses, Yews and their allies, until we reach the Pines and Firs, which are arranged at the head and along the southern side of a noble expanse of ornamental water whence the supplies for garden purposes are pumped by engines at some distance away in the wood. Just across the Thames at this point is Syon House, a place rich in historical associations. A little to the left is the Isleworth entrance, and on the left bank of the river a short distance up the stream, is the pretty village of Isleworth. Following the course of the Thames we go through a very rich collection of Oaks; behind this strip and between it and the wood is a dell in which Rhododendrons luxuriate. After the Oaks come the Elms, and the extremely numerous and very varied forms of our native species are particularly puzzling. The Oaks and Elms practically occupy a considerable tract of ground, the whole length of the river frontage of the Arboretum; here and there, however, are groups of Conifers to block out the sight of the Brentford docks on the opposite bank of the stream. Not far from here Edmund Ironsides defeated the Danes in 1016, and more than six centuries later Prince Rupert gained a victory over the Parliamentary troops.

Bridge at Leathertor, England, page 52.

The village of Kew is situated on the right bank of the Thames about six miles from Hyde Park Corner, and was a royal residence as far back as the reign of Henry VIII. The chief entrance to the Gardens (there are five public entrances altogether) is upon Kew Green, one of the most delightful of the tree-shadowed stretches of sward which form such a pleasant feature of many of the villages in the neighborhood of London. About three hundred yards in a westerly direction from the large and handsome wrought-iron gates stands the Dutch House, or, as it is now always called, Kew Palace, a homely structure of red brick, said to have been erected in the time of James I. by Sir Hugh Portman, a Dutch merchant knighted by Queen Elizabeth. Here it was that Queen Charlotte died. The palace is just outside the garden boundaries and is the property of Her Majesty Queen Victoria. Turning to the left, at a right angle, the main walk—one of the most frequented of the Kew promenades—leads towards the ornamental water in front of the great Palm House: From the Palm House there is a magnificent avenue of Deodars, terminated—at the Richmond limit of the Arboretum—by the Pagoda, one of the remaining fantastic creations of the first Queen Caroline. Leaving the Richmond entrance to the left and skirting the Old Deer Park—in which

A good proportion of the Arboretum (which covers an area of over 178 acres) is occupied by noble stretches of Oak and Beech woods, with here and there fine specimens of Spanish Chestnut, Horsechestnut and other large trees. Under these grow countless thousands of Wild Hyacinths, or, as they are commonly called in many parts of this country, Blue-bells (*Scilla nutans*). When in flower in May and June the magnificent masses of color attract large numbers of artists. Visitors, too, from central and eastern Europe, whether botanically inclined or not, are struck with the sight.

The Botanic Garden proper is about 70 acres in extent and is famous for its beautifully kept lawns, flower-beds, and single specimens and groups of miscellaneous deciduous and evergreen trees and shrubs arranged for landscape effects—not planted in botanical sequence.

The Arboretum is frequently called the Wilderness, and under this name it is mentioned in "Shandon Bells" by William Black, who makes the hero, Fitzgerald, and his artist friend, John Ross, "go splashing through the mud to Kew, to see what the wilderness part of the Gardens (a favorite haunt of theirs and but little known to the public) was like in driving rain, or in feathery snow, or in clear hard frost, when the red

berries shone among the green." The red berries mentioned by the novelist are those of the English Holly (*Ilex Aquifolium*), of which there are many very fine trees. This Holly, which is made to play so important a part in some of Dickens' tales and in English 'Christmas' literature generally, has brighter red berries and dark green very glossy leaves, and altogether, as an ornamental shrub or tree, is much more attractive than the American Holly (*Ilex opaca*).

Royal Gardens, Kew.

George Nicholson, A. L. S., Curator.

Yucca Treculiana.

THE illustration of this fine tree (Fig. 10 on opposite page), the "Spanish Bayonet" or "Spanish Dagger," of western Texas, is from a photograph of a plant grown in the city of Austin, where, as in other towns of western Texas, it is quite commonly cultivated and forms the most conspicuous garden ornament. Dr. Engelman's very complete description of this species renders it unnecessary to say anything of its botanical characters. The Spanish Bayonet becomes, under favorable conditions, a tree sometimes thirty feet in height, with a slender trunk and wide-spreading branches.* It is common through south-eastern Texas, and extends south across the plains of northern Mexico, where it is associated with *Yucca filifera*, as far south as Saltillo and Parras. It forms on the Texas coast near the mouth of the Rio Grande, just back of the sand dunes, straggling, stunted forests; and further inland low, impenetrable thickets.

Yucca Treculiana was introduced into Europe by the French traveler Trécul, whose name it commemorates. According to Naudin it is very hardy in the south of France, where it flowers freely.

C. S. S.

Cultural Notes.

Hardy Herbaceous Perennials from Seed.

FROM the time the winter Aconites, Snowdrops and Crocuses appear in earliest spring till the bold Tritomas are cut down by hard frost in November, we have among hardy herbaceous perennials an uninterrupted display of flowers. But in order to have them so that we can best enjoy them we must have masses of the finer sorts rather than a single plant of each. Individuals are lost in a landscape; there we want broad colonies of a kind. In the decoration of our gardens one Phlox or one Tulip is of no avail; we want a clump or mass of each. For cut flowers one Iris or one Coreopsis would not help us much; we must have several.

How best to increase our stock of plants and variety of kinds must therefore concern us. *Helianthus*, *Plumbago*, *Larpenite*, *Veronica*, *Phlox* and many others may be readily increased by division, but *Aquilegia*, *Delphinium* and *Pentstemon* should be multiplied by seed. True species usually come true from seed, but garden varieties should, in order to keep them true, be perpetuated by division or cuttings. The seeds of some perennials, *Fraxinella*, for instance, are slow and uncertain to germinate; those of others, the Virginian Spiderwort, for example, come up with the persistence of weeds.

In growing herbaceous plants from seed, the amateur should begin with such sorts as are easily grown, for most perennials are more difficult to raise than are annuals, and need not only care before the seeds germinate, but considerable attention after the seedlings appear. He should also limit his list to suit his garden needs. If his desire is to furnish a small rockery, then choose *Erinus alpinus*, *Erysimum rupestre*, *Dianthus alpinus* and the like; if for edgings in his garden, then grow *Armeria*, *Globularia*, *Chrysanthemum Tchihatchewii* and evergreen Candytuft; if for showy flowers, try Oriental Poppies, perennial Larkspurs and Kœmpfer's Irises.

In raising perennials from seed we can begin at any time: as soon as the seed is ripe and before winter sets in; in the greenhouse in winter or hot-bed in early spring; or in a cold-frame or out-of-doors in late spring. What perennials I raise from seed and do not sow in fall I try to sow and get off my hands before I begin to sow annuals in spring. Be careful not to sow slow-germinating seeds in warm quarters, as a hot-house or hot-bed, else the chances are that the seeds will rot; but seeds that were sown in boxes in fall and wintered in a cold frame,

may be introduced to the green-house in spring with quickening effect.

For convenience sake I treat many perennials as annuals; they germinate and grow readily, and bear a full cup of flowers and seeds the first year. Among these are *Abronia*, *Ageratum*, *Dahlia* (single-flowered), *Delphinium grandiflorum*, *Eschscholtzia Californica*, *Gaura Lindheimeri*, *Leptosyne maritima*, *Lophospermum scandens*, *Mirabilis Jalapa*, *Salvia splendens* and *S. farinosa*. Of course some of these, as *Dahlia* and *Lophospermum*, are not hardy, but, treated as annuals, it matters not whether they are hardy or tender.

If sown early many perennials will bloom freely the first year. These include *Anemone coronaria*, *Anchusa*, *Cedronella cana*, *Conoclinium*, *Delphinium*, *Echinacea*, *Gaillardia*, *Incarvillea Olga*, *Lychnis*, *Malva*, *Platycodon*, *Pyrethrum*, *Salvia pratensis*, *Sidalcea*, and *Stachys coccinea*. Now, while *Coreopsis lanceolata* if sown early in spring will bloom here towards fall, I am informed that in Vermont it will not bloom at all the first year from seed. And the same is true of many other perennials.

There are many kinds of perennials that I have never known to flower the first year from seed. These include *Aquilegia*, *Anthericum*, *Arabis alpina*, *Asclepias tuberosa*, *Astrantia*, *Baptisia*, *Betonica*, *Bocconia*, *Buthalum*, *Callirhoë*, *Chieranthus alpinus*, *Erysimum rupestre*, *Globularia*, *Lathyrus latifolius*, *Iris*, *Lilium*, *Oenothera Missouriensis*, *Orobis vernus*, *Statice latifolia*, *Tritoma* and *Veronica longifolia*.

Perennials that bloom in spring, for instance *Crocus*, *Scilla Sibirica*, *Trillium* and *Sanguinaria* (all of these self-sow themselves abundantly), seldom bloom the first year from seed; but we have an exception in the case of *Anemone coronaria*. On the other hand, perennials that bloom in fall, if sown early often bloom the same year—for instance, Hollyhocks, *Hyacinthus candicans*, and *Montbrietia crocosmiaeflora* (not quite hardy).

Many perennials, when once established, self-sow themselves abundantly. Among these are *Delphinium*, *Coreopsis*, *Gaura Lindheimeri*, *Salvia farinacea*, *Dianthus* and *Digitalis*. Of these, Foxgloves make good perennials with me in sandy land, but in clay soil I have never found them to be satisfactory other than as biennials. Sweet Williams often live over as perennial, but in all cases I have had the best success with them as biennials. And the same is true of *Lychnis grandiflora*, *L. fulgens*, *L. Senno*, and the many varieties of *L. Haageana*. While many of the commoner Pentstemons, as *P. ovatus*, *P. diffusus* and *P. pulchellus*, self-sow themselves with great freedom, the finer species, as *P. Eatoni*, *P. Palmeri* and *P. Cobæa*, have never, under my care, produced any self-sown plants. But at Woolson's, at Passaic, I have seen numbers of self-sown plants of *P. grandiflorus*. While *P. diffusus*, *P. ovatus*, and *P. levigatus* make pretty good perennials, I always have had most success with the other species when they were treated as biennials. The seed should be sown as soon as ripe.

Many perennials germinate as readily as do annuals. Among these are *Anthemis*, *Aquilegia*, *Arabis*, *Armeria*, *Chrysanthemum*, *Conoclinium*, *Delphinium*, *Dianthus*, *Digitalis*, *Eupatorium*, *Gypsophila*, *Iberis*, *Iris*, *Lobelia*, *Lychnis*, *Malva*, *Pentstemon*, *Primula*, *Sedum*, *Sempervivum*, *Thalictrum*, *Thymus*, *Tritoma*, *Viola* and many others. But all the species of these genera do not germinate with equal facility—for instance, while *Pentstemon ovatus* comes up thickly and in about nine days, *P. cobæa* never comes up a full crop nor regularly. And the freshness of the seed has a great deal to do with its germination. I have never succeeded in raising plants of *Dictamnus*, *Primula Japonica* or *P. rosea* from seed a year old. Seeds of leguminous plants, especially of *Thermopsis* and *Baptisia*, even if the seed is fresh, germinate very irregularly. I have had a fair crop come up within a month after sowing, and the balance of the seed lie in the ground for a year and then grow. While *Lilium tenuifolium* and *L. pulchellum* will come up a full crop within a fortnight from sowing time, I have found that *L. auratum* and *L. superbum* take several months before they germinate. Seeds of *Clematis graveolens* and *C. tubulosa* germinate readily in a few weeks, but the hybrids so common in our gardens take months.

All hardy perennials, except such as we treat as annuals, had better be sown in late summer or fall; in fact, as soon as the seed is ripe. By this means, in the case of seeds that ripen early and germinate readily, as *Aquilegia*, *Aubrietia*, *Alyssum saxatile*, and the like, we can have fine strong stock before winter sets in, and which will bloom nicely next year. In fact, in the case of most all, except some Lilies, Clematises, Pæonies, Hellebores, Globe Flowers, and Siberian Corydalis, which if sown as soon as ripe do not germinate till the next spring, and Gentians and Composites that bloom late, we may reasonably

**Yucca Treculiana*, Carrière, *Rev. Hort.* 1858, p. 580; 1861, p. 305; 1869, p. 406, f. 82.

expect to get strong stock to keep over in beds or cold-frames.

I make two sowings, one as soon as the seeds are ripe as stated above and another in November. This last sowing includes *Aster*, *Adonis*, *Aconitum*, *Asperula*, *Astragalus*, *Baptisia*, *Clematis*, *Dicentra*, *Epimedium*, *Euphorbia corollata*, *Gentiana*, *Gillenia*, *Heleborus*, *Hepatica*, *Lilium*, *Iris*, *Mertensia*, *Monarda*, *Orobis*, *Phlox*, *Polygonum*, *Paeonia*, *Trollius*, *Uvularia* and *Viola*. These are sown in flats (shallow boxes) filled with sandy soil, and a thin layer of moss is laid over the surface to prevent undue drying. The boxes are then placed in a cold frame, there to remain over winter. Very few of the kinds will germinate before spring, but most all will come up the following April or May, when the moss should be removed from about the seedlings, and they attended to in the way of light, ventilation, water and transplanting.

W. Falconer.

The Cultivation of Lilies.

A COLLECTION of rare Lilies is seldom seen in our gardens, and yet no other class of plants is more greatly desired or as often tried.

Experience with Lilies has convinced me that nearly every variety can be successfully grown with as little trouble as any other plant of equal merit, and that failure is in the main due to overestimating their hardiness. It is the general opinion of those having authority to speak for the Lily, that, with but few exceptions, the species are perfectly hardy. This opinion finds encouragement in the "Cultural Instructions" of nearly every catalogue, and the trustful planter who does not take the proper precaution loses his bulbs. Nearly all the species are natives either of cold or temperate climates,

and therefore it is assumed that all can endure the rigor of our winters. But the fact is that few of the species are truly hardy in this climate except those indigenous to the soil. While it is true that some of the species are found in the coldest part of the habitable globe, growing most luxuriantly, it is equally true that the same species cannot endure our winters without protection. Few climates are so trying as our own to those bulbous-rooted plants, which are usually considered hardy and left in the open border during the winter. This is particularly true of the coast climate, from Massachusetts to Virginia, where there is frequently forty degrees of frost, and not a particle of snow on the ground for protection. Here the earth is frozen to a great depth one week, and thaws out the next. These frequent changes from water to ice and back again cause the earth to contract and expand to such a degree as to tear the bulbs in pieces. I have seen large plantings destroyed in this manner.

But to be more specific. The beautiful *Lilium tenuifolium* is a native of Siberia, where it is largely cultivated as an article of food. Of course it can endure a Siberian winter, but a Long Island winter kills it. Why? Because in its original home the first indication of winter is a snow-storm which covers the ground so thickly that frost rarely, if ever, penetrates it; while here the unprotected earth is frozen far below the Lily bulbs over and over again between November and April. The same is true of the *Lilium Martagon*, the bulbs of which are much valued by the Cossacks as a vegetable. With them it is perfectly hardy; in our warmer climate it will rarely survive more than a single winter without protection, but with that precaution it grows with more vigor here than in its native home.

The White Turk's Cap Lily (*L. Martagon alba*), in the northern parts of New York, in the Eastern States and in Lower Canada thrives with all the vigor of a native plant. So common is it in one locality in St. Lawrence County, N. Y., that a friend sent the writer some flowers for name, saying it was a common wild Lily, but she could not find it described in Gray's "Botany." Here we can only grow it in a cold-frame; because it misses the blanket of snow that covers it in Germany, its native home, and in our own more northern latitudes.

In Vermont, where the ground is nearly always covered with snow during winter, all kinds of Lilies grow to the greatest perfection. We have seen finer bulbs of the *L. auratum*, *L. Brownii*, *L. chalcidonicum*, *L. Martagon*, and other species, grown in that State without the slightest artificial protection, than we have ever known produced in any other country.

There are many other plants protected by snow in a similar manner. We notice on the Alps, at an elevation that permits of but four months of spring, summer and autumn, that the wild Primrose grows in the greatest profusion and luxuriance. It is there constantly covered with snow during their long periods of freezing weather. In the valleys below, where there is no snow and but little frost, the same plant will not live through the winter unless carefully protected.

All that Lilies require for their perfect development and rapid increase is protection against frost, and this is a simple and inexpensive operation. The best and most natural covering is about six inches in depth of newly fallen leaves, kept in place by a few boughs or pieces of board. Salt or marsh hay will afford excellent protection; corn-stalks answer a good purpose; in short, whatever material is the most convenient is the best to use, if it will only protect the bulbs against a temperature that changes repeatedly from one side of the frost line to the other.

C. L. Allen.

Eriostemon intermedium.—This is a South Australian shrub with rigid branches, small, shining, dark, pungent, evergreen leaves, and white flowers tinged with pink. These are axillary and borne in profusion along the primary and secondary branches. *Eriostemon* belongs to the same family as the Orange, which it resembles in the size and shape of its flowers. This is one of those beautiful, old-fashioned hard-wood plants which should be more often seen in our collections. It is very easily cultivated and should be potted in turfy peat mixed with sand. It requires careful drainage and the protection in winter of a cool green-house. In this climate it should, in summer, be plunged out of doors, in partial shade. It flowers in March. A figure of *Eriostemon intermedium*, which is considered by Bentham in his Flora of Australia as simply a form of *E. myoporoides*, was published in the *Botanical Magazine*, t. 4439.

Boronia megastigma is another Australian shrub of the Rue family, which is too rarely seen in our collections. It is chiefly valuable for its deliciously fragrant flowers, a small spray of which will scent a whole room. *B. megastigma* is a slender, delicate shrub, sometimes two feet high, with erect branches and spreading opposite branchlets. The flowers are very freely produced from the axils of the sparse, linear leaves towards the ends of the branches. They are solitary, drooping, about half an inch in diameter and sub-globose; dark red-brown on the outside and clear yellow within. This plant, which is now quite commonly cultivated in some London nurseries on account of the fragrance of its flowers, requires cool green-house treatment and should be potted and grown like a Cape Heath. It flowers in March and April. A figure of *B. megastigma* was published in the *Botanical Magazine*, t. 6046. C. S. S.

Milla biflora in our Gardens.—Mr. Pringle's interesting note, p. 20, reminds me that four years ago a large consignment of *Milla biflora*, *Bessera elegans*, and some other bulbs, from Mexico, were disposed of at auction in New York at ridiculously low prices. Most of these bulbs were purchased by Long Island growers, and have, since then, been grown by some of our florists for cut-flowers in summer, for the New York market. The bulbs are planted out in rows in spring, and cultivated by horse power as we do Tuberoses and Gladioli; in the fall they are lifted and treated like Gladioli or Tigridias. While out-of-doors in summer they grow well and bloom beautifully, seldom bearing fewer than two, oftener seven or nine flowers on a scape. The flowers are white and showy, and were picked every day for market. When left un-picked, they set and ripen seed freely. Seeds germinate easily.

Lilium Grayi.—I found this rare Lily, figured p. 19, perfectly hardy at Cambridge, Massachusetts, and as amenable to cultivation as were *L. Canadense* or *L. superbum*. Referring to my note books I find: "1882, July 2d—*L. Grayi* in full bloom; *L. Canadense* not yet in bloom, but its flowers are ready to open." "1883, July 2d—*L. Grayi* in full bloom; *L. Canadense* also in full bloom." The two species were growing near each other in the garden. Their general contour, to a casual observer, is very much alike. The most striking difference is in the flowers; while those of *L. Canadense* are always nodding and the petals reflexed, those of *L. Grayi* are never quite pendulous nor widely open, nor are the petals at all reflexed. The flowers of *L. Grayi* are of a darker red color than are those of the ordinary red *L. Canadense*, and the inner surface of the petals is more thickly spotted with dark purple spots.

Forcing Azaleas.—In order to have Azaleas to bloom early get them to make their growth early. It is not well to take plants that are in bud and bring them into brisk heat in order to bring them into bloom; better bring them into heat after they have finished blooming and get them to make their growth early, and in this way advance their time to bloom.

Cytisus Canariensis.—As soon as it has done blooming cut it back enough to give the plants a shapely, stocky form; then give them a thorough washing in warm water (at a temperature of 125° Fah.) to rid them of red spider, to which they are very subject, and a fortnight after repeat the washing. Do not repeat till they have started into fresh growth. It does not pay to keep over old plants; raise a few fresh ones from cuttings every year. Cuttings of the young wood strike freely. The plants are in their prettiest condition when they are two to three years old. W. F.

Grapes for Home Use.—I cordially agree with Mr. Williams' notes on a choice of varieties. The kinds he has named have thrived well on my grounds and have yielded good fruit. The shores of the Hudson are better adapted to the growth of the vine than the greater part of New Jersey, and we can cultivate successfully some of the more delicate and fastidious sorts. The Iona appears to me to be the most delicious of all the Grapes and is well worth a trial. The Agawam and the Lindley have proved with me good growers and abundant bearers. The fruit is superior in quality, but the clusters are rarely compact and handsome. This defect is of minor consequence in the home garden, where flavor is of the first consideration. On warm, well-drained slopes I can ripen the Isabella and Catawba, and I should be sorry to be without these old and superb varieties. We need late as well as early Grapes. The Bacchus is known almost exclusively as a wine Grape, but about the middle of October it becomes a fine table sort. I have about 112 varieties growing on trial, and hope to be able hereafter to offer some more definite and practical notes.

E. P. Roe.

The *Retinisporas*.

THE generic title of *Retinispora* for a peculiar group of Japanese Conifers, is quite expressive, as it relates to its main distinctive feature, *i. e.*, "retine," resine, and "spore," seed, in allusion to the numerous little resinous vesicles found dotted over the surface of the seed-covering.

Since this genus was established by Siebold and Zuccarini, these resin-dots have been detected in other members of the *Cupressineæ*, notably in *Cupressus Lawsoniana*, and as the other characters were unimportant, *Retinispora*, consequently, can no longer stand. Dr. Maxwell T. Masters, in his admirable paper on the "Conifers of Japan,"* read before the Linnæan Society of London, has very justly reduced the former genera *Retinispora*, *Biota*, *Chamæcyparis* and *Thuioopsis*, to sections of the old genus *Thuja*, and after a careful examination I am ready to concur in his classification.

The object of this paper is to review briefly the most valuable Conifers which have been popularly cultivated under the heading of *Retinispora*, but in the interest of correct nomenclature it has been deemed advisable to adopt Dr. Masters' arrangement.

Perhaps the most satisfactory species for all purposes, is *Thuja pisifera* (*R. pisifera*), a medium-sized tree found in various localities throughout Japan, especially in the mountain districts. This Conifer has proved entirely hardy in the Middle States, growing rapidly when fully established, and forming graceful and attractive specimens with little care. The following have been reduced to varieties of the above species, and although differing widely in general appearance, the organs of fructification in every instance point conclusively to their origin.

Var. *plumosa* (*R. plumosa*) is one of the most valuable forms of this group. The young branchlets have been compared to ostrich plumes, on account of their graceful habit and feathery growth. It forms a compact, small specimen, with numerous small, pointed, bright-green leaves, and in rich, light soil soon forms a conspicuous object on the lawn. The variegated sport from this variety is one of the most distinct and best Conifers of its class for planting in the mixed Conifer border, and its rich, golden tints, especially in early summer, brighten up a mass of dark foliage with remarkable effect.

There is another attractive sport from this variety that has been introduced into our collections under the name of *R. plumosa argentea*. It differs from the above in having numerous little pure white dots scattered over the foliage in an interesting manner. It has the merit of not scorching as so many variegated plants do, and although not remarkably distinct, it is nevertheless entitled to notice.

Var. *squarrosa* (*R. squarrosa*) of Veitch, for there are two distinct forms of this variety under the same name, is perhaps next in importance as a small evergreen tree. Although it is claimed by some writers to be a form of *T. obtusa*, the fruit is identical with *T. pisifera*. An accidental sport from a specimen growing in the Lawsons' nurseries, at Edinburgh, afforded additional evidence of its *pisiferoid* character. It is a remarkably elegant, dense-growing Conifer, with peculiar silvery foliage, and is rarely injured by the severity of our winters after reaching the age of eight or ten years. To preserve a fine conical outline, specimens should be sheared annually for a few years after planting. The other form, which is known in some collections as *R. squarrosa* of Siebold, is not so hardy as the above, and is undoubtedly nothing more than *T. pisifera* or *T. obtusa* in an abnormal state. It is rarely satisfactory excepting when very young.

Var. *filifera* (*R. filifera*) is a peculiar form with the same whip-like branches and branchlets that characterize the pendulous variety of the Chinese Arbor vitæ; indeed it has been surmised that this variety may be another form of *Thuja orientalis*. It is, however, much more elegant than the latter, being entirely devoid of stiffness, and in time develops into a large evergreen shrub with the outer surface completely covered with a mass of slender, drooping, bright-green shoots. It is quite hardy, and desirable even in the smallest collection.

Var. *aurea* (*R. pisifera aurea*) is a distinct and showy form that originated in an English nursery a few years since. The foliage, both old and new, is plentifully marked with a bright golden-yellow tint, which, in partial shade, is retained throughout the summer months. In some localities it becomes discolored when exposed to the full rays of the sun. It is very distinct when placed among other forms.

T. obtusa (*R. obtusa*) is a hardy, valuable tree for this country, although inferior as an ornamental specimen to the preceding species. On the Island of Nippon, in Japan, it

attains a very large size, and forms extensive forests, the timber being in great demand. Its general aspect is open, and on this account it will not prove so popular as many of our own Conifers. This defect, however, may be remedied in a great measure by a systematic annual pruning in the tree's younger years, to increase the number of its branches. It is readily distinguished from *T. pisifera*, but more especially in the size of its strobiles, which are from seven-eighths of an inch to one inch in diameter, while those of the latter are only three-eighths of an inch in diameter. The varieties of the two species are also very distinct. As is the case with most Conifers of long cultivation *T. obtusa* has many curious morphological forms. Some of these are very attractive and deserving of general cultivation, but others are unworthy of dissemination.

Var. *lycopodioides* (*R. lycopodioides*) is the most distinct of all of these recognized varieties, and with generous culture in proper soil it is exceedingly pleasing. The foliage is of the darkest shade of green, and is remarkable in its arrangement, frequently imparting to the numerous short branchlets an appearance of dark-green coral. The habit of the plant is rather dwarf, dense, and irregular in outline, at least for several years after planting, and its constitution is hardy and reliable. In fact, it may be classed as one of the best of this group for general cultivation.

Var. *filicoides* (*R. filicoides*), the elegant fern-like variety of this group, is entirely satisfactory when in its young state, but we have no knowledge of its behavior at maturity, or even at eight or ten years of age. Its cones although smaller than those of its parent show the specific relationship. Many of the small branchlets are flattened out in a peculiar manner which has been likened to the fronds of a fern. The color is especially pleasing, being of a bright-green tint, with the usual glaucous lines on the under side. It appears to withstand the severity of our variable winters as well as its congeners, and in congenial soil quickly develops into a charming evergreen shrub. Judging by its manner of growth, however, it may not become so dense as some, but its other pleasing characters may recompense the owner for the loss of this.

Var. *nana* (*R. obtusa nana*), and Var. *pygmaea* (*R. obtusa pygmaea*), are choice little dwarfs, best suited for the outer edge of clumps and mixed borders. Of the two, the latter is much the smaller plant, with spreading habit and attaining only the height of one foot. They are both hardy and well adapted to our climate.

The variegated forms of this group of Conifers are very numerous, but as they are not especially interesting to the American planter they are omitted from this list. Others again differ from the species in being more slender in growth or dense in habit, etc. There is here a broad field for experiment and research, and Japanese gardeners have not been idle in hunting them up. Their collection of these pretty little oddities is almost beyond number. Many of them, however, are of no possible use for gardening effect, and their culture here would be a mere waste of time and money.

Snowberry Jelly.

MY attention was recently called to an interesting use of the Creeping Snowberry (*Chiogenes hispidula*, Torr. and Gr.) which may prove of sufficient novelty to warrant calling attention to it. A friend forwarded a small pot of jelly, with the request that information be given as to the material of which it was composed.

A superficial examination showed the jelly to be of the color of amber, and about the consistency of Guava jelly. This I subsequently learned to be due to an accident, owing to which very considerable consolidation had followed. The normal consistence is that of ordinary Currant jelly. The upper portion of the mass was quite clear, while at the bottom were numerous small seeds and much pulpy matter, giving a very peculiar character to the preparation, without, however, destroying its value. Upon submitting it to the taste, the flavor was found to be distinctly that of *Gaultheria*, although I have since been somewhat surprised to learn that so distinctive a flavor had not been recognized by several persons. Upon boiling out the pulpy deposit, it was found to consist of the berries constituting the material employed. Many of these were quite whole, so that their true nature was determined without much difficulty, and as we later learned that the berries in the fresh state were perfectly white, it was easy to refer them to the common Creeping Snowberry.

It appears that in Newfoundland, whence the jelly was obtained, it is a common practice with many families to prepare this exceedingly delicate preserve, but the scarcity of the berries,

*Journal Linn. Soc., xviii. 473.

to collect one quart of which an entire day is required, renders it a luxury, and to obtain more than a small quantity is difficult.

The comestible qualities of these berries are well known, and are referred to by Purvancher, "Baies d'un blanc pur à la maturité, très sucrées, comestibles."

The same author further remarks that "Les feuilles et les fruits ont une saveur analogue à la Gaulthéria ou à l'écorce du Bouleau-Merissier. On en fait des infusions d'un goût fort agréable, dont on use en guise de thé dans certains endroits de nos Campagnes."* It is also of interest to note that the local name of this plant, i. e., in Newfoundland, is Capillaire.

The use of the berries of *Chiogenes* as a source of jelly, suggests that the fruit of its near relative, *Gaultheria*, which is certainly more abundant, might be utilized in a similar manner with equally good results.

"Landscape Gardening—A Definition."

To the Editor of GARDEN AND FOREST:

Sir.—The thoughtful article under the above caption in the first number of GARDEN AND FOREST is needed to correct a current misconception concerning the sphere of the landscape gardener. Mere ingenious design, skillful arrangements of bedding plants and conspicuous eccentricities, are frequently mistaken for landscape gardening. Many self-styled landscape gardeners are responsible for this absurd error. They hide and destroy the very art which they profess to cultivate. Flower beds, fountains, and other objects which should be mere accessories, are made the leading features in many parks. To these objects the people point as examples of landscape gardening! With the same reason one might call a handsome dormer-window a complete example of architecture!

As Fine Art is a conception of the mind, it follows that, in order to render it material, tangible, we must employ some mechanical or industrial art. The architect depends upon the carpenter and mason for the labor of construction. So landscape gardening, the Fine Art, depends upon the industrial art which shapes the ground, plants the trees, makes the walks and drives. This industrial art is no doubt a legitimate branch of horticulture. It is the sphere of the artisan. To call this artisan an artist, a landscape gardener, is like calling the amanuensis who writes the conceptions of Longfellow a poet. In my own teaching I have given this industrial art the name Landscape Horticulture, for such it is. Nearly all our professed treatises upon landscape gardening do little more than designate the most important rules and operations of landscape horticulture. This is the case largely of necessity, for it is a difficult matter to give adequate instruction in a Fine Art. It does not deal in formulas. But horticulture allows of closer rules, and for convenience of treatment I divide it into four broad divisions: Pomology, Olericulture or Vegetable Gardening, Floriculture, Landscape Horticulture.

Fraxinella.

To the Editor of GARDEN AND FOREST:

Now when garden-lovers are beginning to think about plants for the coming season, and when so many new ones are being brought to their notice through your columns, may I say a word in behalf of an old flower which ought to be more often seen?

Fraxinella (*Dictamnus Fraxinella*), a native of Southern Europe and some parts of Asia, has been cultivated for fully three centuries in England and was esteemed by our grandmothers with the best of those flowers which we call "old-fashioned." To-day it seems almost forgotten. I have chanced to see it only once—in a garden near Boston—and although I have spoken of it to many persons, I have met none, except the owners of this garden, to whom it was familiar.

It belongs to the Rue Family, and is a perennial herb with an almost woody base and very graceful foliage—the pinnate leaves with many serrate leaflets, like those of the Ash on a smaller scale, having given rise to its common name. The flowers are rather large and borne in a long terminal raceme in summer. In one—the prettiest—variety, they are white; in the other, Gray, in the "School and Field Book of Botany," describes them as "pale purple with reddish veins," but I should call them dull pink with reddish veins. Their irregular shape—unique in the Rue Family—their size and arrangement, suggest in some degree the Larkspur, but *Fraxinella* is more delicate and graceful. Its chief distinction lies, however, in its odor. Gray calls this odor

"strong and aromatic," and it is this and more—very strong, very aromatic, very sweet, and quite unlike the scent of any of our common garden-blossoms. There is a hint of vanilla about it, and a certain richness and penetrating quality which betray its southern origin. Yet, although rich, it is not heavy, but as fresh as the smell of lavender. *Fraxinella* is also an object of interest from the fact that the volatile oil generated by its flowers is so strong that on warm, still, summer evenings a lighted match held a foot above them will cause a flame to burst forth.

Philip Miller, in his "Gardener's Dictionary," published in 1724, says of *Fraxinella*: "These plants continuing a long time in Beauty, are very great Ornaments to a Garden; and their being very hardy, requiring but little Culture, renders them worthy of a Place in every good Garden." *Pequot*.

New London, Conn.

[*Dictamnus Fraxinella* ought not to be uncommon in American gardens. It deserves a place in every collection, however select, of hardy herbaceous plants. It is easily propagated by seed or division, and will flourish in any garden soil.—ED.]

The Forest.

Forest Trees of the Far North-west.

THESE notes refer to an area which includes the extreme western part of British Columbia, with adjacent portions of the North-west Territory, as well as part of the "Coast strip" or southern part of Alaska. The area is embraced in a general way by 56° 30' and 63° north latitude, the 128th and 138th degrees of west longitude. Through this almost unknown portion of the continent a geographical and geological reconnaissance was carried last summer by the writer, on behalf of the Geological Survey of Canada.

The region in question is drained by the Stikive and other rivers which flow through the coast ranges to the Pacific, by the Liard, a main tributary of the Mackenzie, and by several branches of the Yukon. These large rivers form routes of travel through the country, but the several drainage basins do not constitute regions of diverse Floras. The great division from this point of view, is found between the humid climate of the coast and the relatively dry and extreme climate of the interior; the first constituting the continuation of the botanical region of the British Columbian coast, the second that of the interior of the same province. The considerable altitude of the interior also has its influence on the vegetation. The average "base level" or valley level of the interior is about 2,500 feet. Difference of latitude shows a comparatively small effect, in consequence of the fact that the country as a whole becomes lower northward. The region may, generally speaking, be described as mountainous, though there are as well large tracts of low lands and the river valleys are generally quite wide.

The chief facts to be recorded with respect to the distribution of trees are those bearing on the northern limits of the well known western forms, the number of species represented so far north being quite restricted. In the interior region, which may be treated as a whole, the Douglas Fir, Engelmann's Spruce, the Hemlock (*Tsuga Mertensiana*), and the red Cedar (*Thuja gigantea*), all common and characteristic trees a few degrees to the south, are nowhere found. The White and the Black Spruce (*Picea alba* and *P. nigra*), Balsam Fir (*Abies subalpina*), Aspen (*Populus tremuloides*) and Cottonwood (*Populus trichocarpa* probably with *P. balsamifera*) occur in suitable localities over the whole region east of the Coast Mountains, the two first-mentioned trees constituting probably half the entire forest-covering of the country.

The White Spruce, along the rivers and in low ground, forms fine well grown groves in which many trees attain a diameter of two feet, to the most northern point reached, and affords timber of fair quality. It is found with *Abies subalpina* at the upward limit of forest growth on the inland mountains, about 4,200 feet. The Black Spruce has scarcely received mention in previous notes on the distribution of trees in British Columbia, but is now known to be abundant locally on high plateaus about the region of the upper Fraser, and in the country here described is common in swampy places and along shaded river-banks with a northern exposure. It attains a considerable height, but is never large enough to afford good lumber. *Abies subalpina* was found wherever the upper limit of trees on the mountains was approached, but was not observed near the rivers, except on Bennett Lake, near the head of the Lewes, in latitude 60°, where it is very abundant. The Aspen is especially characteristic of second-growth woods and dry open grassy hillsides, of which there are many along the Pelly and Lewes branches of the Yukon. The Cottonwood here

* *Flore Canadienne*, 363.

represented is, in so far as the specimens brought back can be determined, *Populus trichocarpa*, but there is little doubt that the Balsam Poplar also occurs. Trees six feet in diameter were seen on the Stikive River, but further inland they were very rarely found to reach a diameter of three feet.

Greater interest, from a botanical point of view, attaches to the trees of which the ranges are more restricted. The Black Pine (*Pinus Murrayana*), so common in the interior to the south, is also pretty widely distributed in this northern country. It is found in abundance on the Stikive immediately to the east of the coast mountains and thence inland. It was observed on the Dease and Upper Liard, and from the mouth of the Dease (according to specimens sent back by Mr. R. G. McConnell), down the Liard to Devil's Portage, some miles east of the range which appears to represent the northern continuation of the Rocky Mountains proper. Further east, the Banksian Pine becomes characteristic of the great valley of the Mackenzie, which is here entered; but this tree does not extend to the west of the Rocky Mountains, on the head-waters of the Liard. *Pinus Murrayana* reaches nearly to Finlayson Lake, its most northern source, but does not occur on the Upper Pelly, in descending which it was first met with in longitude 133° 30'. From this point, down the Pelly and up the whole length of the Lewes, it is moderately abundant. On the authority of Mr. W. H. Dall's northern limit of this tree has been given as at the confluence of the Pelly and Lewes (lat. 62° 49'), but as it there shows no sign of having reached its extreme point, it may probably be found some distance further northward in the Yukon Valley, though not as far as the mouth of the Porcupine, in latitude 66° 33'.

The known range of the common Larch (*Larix Americana*) has by the observations of the past summer been definitely carried to the west of the Rocky Mountains. It extends westward on the Dease River to a point twenty-two miles above the mouth of that stream, and along the upper Liard and Frances Rivers spreads northward nearly to Finlayson Lake, reaching latitude 61° 35'. Between these limits it is abundant and characteristic of cold, swampy ground. It was looked for all along the Pelly, but not found either on this or the Lewes branch of the Yukon. It appears probable, however, that this tree will eventually be proved to characterize the sub-arctic country, further to the north, from the Mackenzie Valley nearly to the shores of Behring Sea, as Dall, in his well known work on Alaska, mentions the occurrence of a Larch on the lower Yukon (as *L. microcarpa?* and *L. Davurica?*), which can scarcely be any other than this species. *Larix Lyallii*, which about the 49th and 51st parallels in the Rocky Mountains is the most characteristic tree at the timber-line, was not found in the region now in question and would therefore appear to be a relatively southern mountain species.

The Birch (*Betula papyrifera*) was first seen to the east of the coast mountains in the Stikive Valley and occurs sporadically along the river-valleys throughout the interior. It is quite abundant on Frances Lake, near the head of the Liard, but was not observed on the upper Pelly east of the 131st meridian.

Juniperus Virginiana was observed as a small tree, with trunks six inches in diameter, at Telegraph Creek on the Stikive in the dry country in the lee of the coast mountains, but was not elsewhere found in an arboreal form. The Alder (probably *Alnus rubra*) and one or more species of Willow become small trees along some of the rivers of the interior, the Alder being noted as specially abundant and large on the Pelly above the mouth of the Lewes.

As already noted, the timber-line was found to be at about 4,200 feet on the mountains of the interior near the watershed between the Liard and Pelly (lat. 61° 30'). At a similar distance from the Pacific coast, in the corresponding range of the Cordillera in latitude 51°, this line is at an altitude of about 7,000 feet, showing a descent to the north of 2,800 feet in ten and a half degrees of latitude, or about 280 feet for each degree.

It is generally stated that the influence of the warm waters of the Pacific "Gulf stream," reaching the northern part of the west coast and flowing southward along it, is such as to produce a nearly identical climate and Flora from the Strait of Fuca far to the north. While this is true in a general way, it is a mistake to suppose that no effect is produced by increasing latitude. The most marked change of climate, as indicated by the arboreal vegetation, nearly coincides with Dixon Entrance and the 54th parallel. North of this the forest is usually inferior in growth and the quantity of marketable timber is much smaller. The Red Cedar (*Thuja gigantea*) is not found in any abundance, north of the latitude of the mouth of the Stikive, and though closely looked for along the coast in the vicinity of Lynn Canal, no single specimen of it was detected there.

The Yellow Cedar (*Chamaecyparis Nuktaensis*) scarcely reaches Sitka, and is not anywhere found among the inner islands near the entrance of Lynn Canal. The Alder (*Alnus rubra*) forms groves along the shores at least as far north as latitude 59°. The western Crab-apple (*Pyrus rivularis*) occurs here and there as far north as Lynn Canal. The Broad-leaved Maple (*Acer macrophyllum*) may reach latitude 55° as stated by Prof. Sargent in his Census report, but was not observed by me, and must be rare. North of the Prince of Wales Archipelago, eight-tenths of the entire forest of the coast region appears to consist of the single tree Menzie's Spruce (*Picea Sitchensis*).

Pinus contorta was noted at the head of Lynn Canal and elsewhere along the coast. Here also, in the valley of the stream on the west side of the Chilkoot or Perrier Pass, by which the coast mountains are crossed, *Tsuga Pattoniana* grows to a fair size and forms entire groves. It was found as well within a few hundred feet of the summit of the pass at an altitude exceeding 3,000 feet, in a prostrate form, but still frequently bearing cones. *Abies amabilis* (?) was also noted in the valley of the west slope of the pass and occurs along Lynn Canal and other parts of the coast. Unfortunately no cones of this tree were found.

I am indebted to Prof. J. Macoun and Prof. C. S. Sargent for the determination of most of the specimens of trees collected.
George M. Dawson.

The Forests of New Jersey.

PROFESSOR Geo. H. Cooke, Director of the State Geological Survey of New Jersey, states in a recent report that the total area of woodland in that State amounts to 2,069,805 acres, or 41.5 per cent. of the total area of the State. The growing of Chestnut timber for railroad ties on the untillable lands of northern New Jersey is recommended, as there is always a demand for them by the numerous railroads crossing the State in every direction. Chestnut stump-land sells for from \$1.00 to \$5.00 per acre, a growth of thirty years at from \$10.00 to \$30.00 an acre; of fifty years from \$25.00 to \$50.00 an acre. But in many cases good growths, accessible to markets, have sold at figures three to four-fold greater. The value of the timber depends much on the soil and the location. The time required to grow ties and telegraph poles will average about thirty years. In the northern part of the State the Chestnut grows naturally, and brings the quickest and best returns, although Oak is more valuable when grown. It has been demonstrated that Locust timber can be grown with profit on the 250,000 acres of waste land on the cretaceous formation. It is possible to raise on good land a crop worth \$3,000 per acre in thirty years, and returns at the rate of \$2,000 are not uncommon. The growing of White Cedar timber is generally recognized as profitable. The value of stump-land is from \$5.00 to \$10.00; of twenty years' growth of timber from \$5.00 to \$50.00; of thirty-five years from \$15.00 to \$200.00; and of fifty years growth from \$75.00 to \$400.00. Of course, location and size have much to do with the price. A swamp of seventy years' growth recently sold for \$800.00 per acre.

The Pitch Pine (*Pinus rigida*) in the southern and central parts of the State attains a size suitable for firewood in about fifteen or twenty years. It is commonly estimated that it will produce as many cords per acre as it has been years in growing. The present value of Pine wood per acre standing averages about \$1.00. When the timber becomes larger, its value per cord increases, and it finds a market for lumber and lath, for piling and other purposes. The following figures are from estimates of men familiar with the Pine forests, and the wide range is due to difference in accessibility and the producing power of the land. Pine stump-land ranges from \$0.10 to \$5.00 per acre. Of course, this does not include the figures from localities where the land has a value of from \$10.00 to \$25.00 per acre for cultivation. The value of thirty years' growth of timber is from \$5.00 to \$25.00; of fifty years' from \$10.00 to \$100.00. Taking figures pertaining to the average of the better two-thirds of Pine land as a guide, the present conditions would give about the following results:

Cost of stump land, per 100 acres,	\$250.00
Taxes on average value, 30 years,	448.00
Policing and protection, 30 years,	120.00
Interest, at 6 per cent.,	450.00
Total expenditure,	\$1,268.00
Value of 30 years' growth, for 100 acres,	2,500.00
Value of stump land,	250.00
Total value,	\$2,750.00
Profit,	1,482.00

The interest on annually paid expenses is supposed to be offset by increase in value of stump land.

It is not to be supposed that proper protection and attention will not greatly increase the above profit. These figures represent the present values, depreciated by the results of neglect, and the uncertainty and loss caused by fires.

MONSIEUR Viette, the French Minister of Agriculture, by a recent decree has reduced the Forest School at Nancy to a subordinate branch of the National Agricultural Institute, an arrangement which not only destroys all independence in the management of the school, but compels its pupils to pass an examination in the theory and practice of agriculture—an unnecessary waste of time, it is claimed.

This radical and apparently unwise measure calls forth a loud protest from all the friends of the forest administration in France, who see in it a serious blow to the efficiency both of the school and the management of the forests. This famous school was established by the French Government in 1827. In it have been trained the officers who have made French forests and French forestry what they are, and here have been educated a large part of the Englishmen who have so ably seconded Dr. Brandis and his successors in their Indian forest administration. Any official interference that will impair the value of the Nancy school is a misfortune which must be felt far beyond the limits of France.

Recent Plant Portraits.

Botanical Magazine, February.

Amorphophallus virosus, t. 6978; a native of Siam.

Calogyne Massangeana, t. 6979; a native of Assam and closely allied to the Bornean *C. aspirata*, which it resembles in its large showy flowers borne in drooping racemes a foot long.

Salvia scapaformis, t. 6980; a native of Formosa, with rather small, clear blue flowers.

Aloe Hilderbrandtii, t. 6981; a native of east tropical Africa.

Oncidium Jonesianum, t. 6982; a native of Paraguay and considered by Sir Joseph Hooker "by far the handsomest species of the small group to which it belongs and of which the type may be considered to be the long-known *O. Cebolleta* of the Spanish Main."

March.

Vanda Sanderiana, t. 6983; a free flowering, showy species from the Philippine Islands.

Primula geraniifolia, t. 6984; a neat species with small purple flowers, perfectly hardy at Kew.

Mesembryanthemum Brownii, t. 6985.

Heloniopsis Japonica, t. 6986; a dwarf, hardy, liliaceous plant, a native of Japan and Corea, with the habit of a large-flowered *Scilla*, and drooping, racemose, deep pink flowers.

Onosma pyramidalis, t. 6987; a native of the western Himalayas, "a very handsome plant, conspicuous for the bright scarlet of the flowers, which turn of a mauve-purple as they wither;" not hardy at Kew.

Massachusetts Horticultural Society.

THE Spring Exhibition of this Society was held at Boston last week and was most successful in the abundance and quality of the bulbous plants and flowers displayed, owing to the medals and special prizes offered to promote the cultivation of this class of plants. In form and color these flowers distinctly excelled the exhibits of former years. Cut blooms of Roses of all classes made another striking feature, and with them were a few well grown plants in bloom of the beautiful but scentless "Her Majesty." Orchids were not so numerous shown as at some former exhibitions, although there were some notable specimens in the collection. A fine *Dendrobium nobile*, exhibited by Norton Brothers, showed more than 800 flowers. An Appleton medal was awarded to this vigorous plant. C. M. Atkinson, gardener of Mr. J. M. Gardner, contributed a *Cattleya intermedia* with forty flowers, and W. A. Manda sent a *Dendrochilum glumaceum* with as many spikes. A few examples of the late and rare *Odontoglossum Pescatoria* came from the collection of Mr. H. H. Hunniwell, as did a striking plant of *Gloneria jasminiflora*. The Heaths and Azaleas were especially good. Complaint was made of insufficient room for the proper display of contributions, but the plants and flowers were tastefully arranged, so far as the accommodations would permit.

Flower Market.

NEW YORK, March 23d.

The dullness in trade, and glut of cut flowers early this week, is almost unprecedented in the experience of Metropolitan florists. American Beauty Roses have been sold at 6 cts. each wholesale, and retailed for 25 cts. Jacqueminots were sold for 2 cts. wholesale. This, of course, was not for selected stock. Syringa, Mountain Laurel and Heath, growing in pots, are brought in for Easter novelties. Rhododendrons, Azaleas and Genesta of great beauty also appear. Plants of Mountain Laurel cost \$3; Heath, from \$2.50 to \$5; Genesta, \$2.50, and Rhododendrons, noticeably Cunningham's White, are \$4. Beauty of Waltham Roses have been added to the galaxy of hybrids; they are \$5 a dozen. Fine La France Roses sell for that price, but this Rose daily declines in favor. Puritans have improved, and are very large and perfect. They cost 50 and 75 cts. each. Jacqueminots, selected, bring from \$1 to \$3 a dozen. Hybrids sell from \$3 to \$5 a dozen, according to quality. Gardenias are in good demand at 25 cts. each. *Narcissus poeticus* is \$2 a dozen. Dutch Hyacinths cost from \$1.25 to \$1.50 a dozen. Lilacs are \$1.25 and \$1.50 a bunch of the best stock. Neapolitan Violets are plentiful, and cost from 75 cts. to \$1 a hundred. Marie Louise and White Violets sell for from \$1 to \$1.50 a hundred. Mignonette costs from \$1.20 to \$1.50 a dozen spikes. Smilax is 40 and 50 cts. a string. *Asparagus plumosus* is \$1 a string, and *A. tenuissimus* 75 cts. a string. There are few or no orders for designs for Easter offerings or memorial tokens for the altar. Boxes of cut bloom are preferred for gifts, and expressive arrangements of plants and flowers on the altar *in memoriam* will be the rule.

PHILADELPHIA, March 23d.

From one part of the city comes the report that the past two weeks has been the dullest known for many years. Happily this does not represent the state of the trade in general. The demand for flowers, though not excessive, has been satisfactory. Some very large, fine and highly-colored Magna Charta Roses are to be seen in the florists' windows; also a few exquisitely formed and tinted Captain Christs. It is surprising there are not more of the latter grown, for it certainly is one of the most beautiful varieties. A seedling Rose of European origin is on trial in this city, which promises to be widely known if it can be grown generally as well as a specimen flower which was exhibited here a few days ago. It is said to be a true Tea; but if the flower itself were seen without foliage no one would suspect a drop of Tea blood in it except perhaps from its color. It is rather a difficult tint to describe, reminding one—without an opportunity for close comparison—of Bourbon Queen. In form it is almost perfect, being cup-shaped, similar to Baroness Rothschild, opening regularly and full to the centre. It is very large, and altogether a remarkable Tea Rose. Tulips are in demand at \$1 per dozen, as also are Lilies-of-the-Valley, and Daffodils at same price. Extra fine Mignonette sells at \$3 per dozen. This comes from Summit, N. J. *Primula obconica* is offered in limited quantities at 75 cts. per dozen. This is quite new here as a cut flower. Smilax has become scarce. A supply from other cities will have to be obtained for Easter. Orchids are grown in very limited quantities in this city. The stock carried by the leading florists is obtained from New York and Boston. Of Roses, Md. Gabriel Luizet sells from \$6 to \$9 per dozen; Captain Christy and Magna Charta, \$4 to \$6 per dozen; Mrs. John Laing, \$4 per dozen. Heath, per dozen sprays, \$3. Jacqueminots are good, and sell from \$3 to \$5 per dozen. American Beauties are improving in quality, and are not displaced by the hybrid Remontants, as was predicted would be the case at this season of the year. They sell at from \$3 to \$6 per dozen. Longer stems are being cut of the Beauty than can be cut with the Remontants. Fine Puritans are better than the best Merveille de Lyons just now. Spring flowers generally are very popular. A few bunches of Trailing Arbutus were noticed in some stores. It is a great favorite in this city.

BOSTON, March 23d.

The severe storm had a demoralizing effect on the cut flower trade here and the florists here have found it a rather dull time ever since. Prices have not changed much since last report, some varieties being quoted at a slight reduction. By the time this report appears it is probable that Easter prices will be more acceptable than those of the present moment. Lilies of various kinds will be fairly abundant and quality will be of the best. Harris's Lilies and "Longiflorums" will cost from \$5.00 to \$6.00 per dozen on long stems, Ascension Lilies (*L. candidum*), from \$2.00 to \$3.00 per dozen. The price of Lilies-of-the-Valley, Tulips, Narcissus and similar flowers will increase but little, from \$1.00 to \$1.50 per dozen being the price now asked in advance. Callas have been blooming very heavily and the prospect is not encouraging for a large supply. Florists are now asking \$6.00 per doz. for Easter delivery. In roses there will be a magnificent supply. Some of the best growers of Jacqueminots and other hybrids have timed their houses to bring the height of the crop in at Easter, and there will be no lack of good material for Rose fanciers to select from. Those who are regardless of expense will find fancy varieties as high as \$10.00 to \$12.00 per dozen while more modest customers can get Bon Silene, Safrano, Niphotos and other fragrant and pretty kinds for \$1.00 to \$1.50 per dozen. Large Ferns, Massive Palm foliage, Laurel, Smilax and other greens will be used largely for decorative purposes. The usual supply of Marguerites, Mignonette, Carnations, Forget-me-nots, Pansies, Violets, etc., for mixing with assortments of cut flowers, will be offered in abundance.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.
[LIMITED.]

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, APRIL 4, 1888.

TABLE OF CONTENTS.

	PAGE.
EDITORIAL ARTICLES:—Trees for Planting in America.—Rainfall on the Great Plains.—The Study of Botany by Horticulturists.—The Pink-flowered Dogwood.	61
Landscape Gardening, VI. Mrs. Schuyler Van Rensselaer.	63
Anglomaniia in Park Making. Charles Eliot.	64
Conifers and their Cultivation. Charles A. Dana.	64
Wanted—A Hand-book of Horticulture. Professor Wolcott Gibbs.	65
Phlox adsurgens (with illustration). Sereno Watson.	66
Photinia villosa (with illustration). C. S. S.	67
CULTURAL NOTES:—Epidendrum (Nanodes) Medusa—Coclogyne cristata alba (hololeuca)—Sarcocochilus (Thrixspermum) Berkeleyii—Bertolonia marmorata—Rondeletia (Rogieria) gratissima—Amaryllis Aulica—Phalænopsis Sanderiana—Calanthes—Phalænopsis Harriettis—Freeseias—Hydrangea rosea—Chinese Primroses.	67
Trial Beds. The Rev. Edward P. Roe.	69
Foliage With Cut Flowers. Professor W. W. Tracy.	69
CORRESPONDENCE:—Boronia megastigma—White Pine in Massachusetts.	70
THE FOREST:—The Forest Vegetation of Northern Mexico, I. C. G. Pringle.	70

Trees for Planting in America.

AT this season of the year many persons who desire to beautify the surroundings of their homes by planting, seek instruction with regard to the trees best adapted for their purpose. Instruction upon this subject, especially in a country like the United States, of such varied climatic and social conditions, is difficult to give; sources of information are neither numerous nor very available. Planters are too often obliged to rely upon the advice of dealers and plant-peddlers in the selection of their trees. Such advice is often based upon imperfect knowledge, and nurserymen too frequently recommend the rarest and most high-priced trees or those most easily and therefore cheaply raised in nurseries, without regard to their fitness to the situation for which they are intended. People who would gladly plant trees become discouraged by the difficulty of learning what varieties they can use to the best advantage, or by the failures and disappointments which invariably follow errors of selection.

There is, however, one safe rule in the choice of trees which all persons who are unfamiliar with the subject can safely follow. This rule is to plant only such varieties as they see growing and thriving naturally in the neighborhood of their homes. No teacher in such matters is so wise and so unprejudiced as the forest. The Elms and Maples taken from the adjacent swamps and hillsides, —many of them now more than a century and a half old— which grace the streets of some of the older towns or adorn the early homesteads of New England, and the Magnolias, Live Oaks and Water Oaks seen in the cities and plantations of the South, abundantly testify to the truth of this fact. These are the only really successful examples in America of tree-planting as tested by time. In England, too, it is the native Oaks and Elms and Beeches which give to the land its distinctive aspect, and to its homes their greatest dignity and beauty.

Fortunately, we are abundantly supplied with American trees. In the South, the great evergreen Magnolia, unsurpassed in beauty, the Live Oak, the Water Oak—one of the best of American street trees—the Laurel Oak, the Pecan, the Bays, and many other beautiful native trees, are available to the planter. And it is fortunate that he has been obliged to make use of this material by the fact that few foreign trees of large size will thrive in that climate. In the Pacific Coast States, on the other hand, the conditions which govern planting are different. There are comparatively few native trees and these are confined chiefly to the mountains and the uninhabited portions of the country. The few which grow in the valleys are not in all cases ornamental, and are often difficult to cultivate. There are, however, exceptions. Some of the noble California Oaks surpass in stately beauty any exotic trees which are likely to flourish in that peculiar climate, and serious attempts to cultivate them should be made. And two California Conifers—the Monterey Cypress and the Monterey Pine (*Pinus insignis*)—are already widely and successfully grown from Vancouver's Island to San Diego. Fortunately they are both beautiful representatives of their class. Yet California will doubtless always be obliged to depend somewhat upon other parts of the world for her materials for ornamental planting. The trees of the Eastern States do not flourish there, and it is not probable that those of either Europe or Eastern Asia will ever gain much foothold on California soil. It is to Australia and other dry countries that California planters must look in the future, as they have in the past with such apparent success in the case of the Eucalyptus and of various Acacias.

The settlers of the dry interior region of the continent have not yet found any tree as valuable as the native Cottonwood which fringes the river-banks of all that territory, to protect their farms and orchards and to supply them with fuel.

It is, however, in the Eastern and Middle States that the greatest interest in ornamental planting has been felt, and that the greatest mistakes, arising from ignorance with regard to the true beauty and value of our native trees, have been made. It is in this part of the country that foreign trees have been most generally introduced and cultivated, to the serious injury of parks and homesteads. It is not easy to estimate the amount of this injury, or of the widespread discouragement which must be felt as trees carefully nurtured for a generation show themselves incapable of reaching maturity in our climate. We should have escaped much disappointment if, thirty years ago, our parks and gardens had been planted with native trees instead of the Spruces, Oaks, Ashes, Maples, Pines and other trees of Europe. These trees have been and still are largely planted in this country. They grow rapidly for a few years and are more easily raised in nurseries than many American trees, and are therefore favorites with dealers; but it is now evident that their general introduction was based upon very insufficient knowledge and that their cultivation here has proved a failure.

There are, of course, exceptions. The English Elm has grown successfully in New England for a century; the White Willow is now as much at home in Eastern America as in Europe, and the Norway Maple almost equals here in beauty and vigor some of its American congeners. But, in general, planters in the Eastern and Middle States can do better than depend upon the forests of Europe for their trees. There are not less than a hundred and thirty native trees found in this region, or among the Alleghany Mountains where elevation produces a climate similar to that of more northern regions.

The Silva of no other part of the world is more rich in trees of ornamental value. Its Magnolias, Oaks, Hickories, Walnuts, Maples, Elms and Ashes, its Tupelo, its stately Tulip Tree, its great Rhododendron and Mountain Laurel, its Birches and Lindens, its Coffee Tree, Sour-wood and Sassafras, its Beech—the loveliest of our deciduous trees in winter, and in early spring when its leaf-buds are bursting

—its Chestnut, Yellow-wood and Wild Cherry, its Catalpas, its Persimmon and Silver-bell Tree, its Flowering Dogwood and Fringe Tree, its Liquidambar, Hackberry and Sumachs—among these is surely material enough to satisfy the planter of deciduous trees, however great may be his love of variety. And among coniferous trees there is none more picturesque in youth or more stately in maturity than our northern White Pine, none more graceful and dignified than our Hemlock.

Eastern Asia has given us the Ailanthus, the Pawlonia, the Flowering Apples, the Yulan Magnolias, the Ginkgo and the Mulberry, which are already perfectly at home here; and the similarity in climate and vegetation between that part of the world and our own, leads us to believe that many other Asiatic trees will permanently thrive with us. In addition to those mentioned, many young Japanese trees—especially Conifers—now help to beautify our gardens. But it must not be forgotten that we know no more about the behavior of these trees, as they approach maturity here, than we did of the Norway Spruce, the Scotch Pine and the English Oak when they were supposed to be the most valuable ornamental trees for planting in this country. And this is true also of the Rocky Mountain Conifers, now so largely planted at the East, and of all the exotic trees which have been introduced into California. Therefore, planters who are wise will confine themselves to native trees until arboreta and other experimental stations can definitely teach us which foreign trees can be safely admitted into American plantations.

Rainfall on the Great Plains.

THE future of the Great Plains, as the vast elevated region between the 98th parallel of latitude and the eastern base of the Rocky Mountains is generally called, is a matter of much importance to the American people. The question whether this region is to remain always a quasi-desert, the barren feeding-ground of a few half-starved cattle, or is to become the home of a large and prosperous agricultural population, involves serious political and commercial interests.

The rainfall is light and very unequally distributed. Moisture is insufficient to insure the growth of trees except along the immediate banks of the infrequent streams. Agriculture is precarious. The scarcity of rain is due to the remoteness of the region from any great body of water. It is effectually cut off from the Pacific by numerous lofty mountain ranges, and its only water supply comes from clouds charged with moisture from the Gulf of Mexico—moisture which they have pretty thoroughly lost before they reach the interior of the continent. Here are conditions which no action of man can influence. It is, however, the apparent belief of many persons—especially those more or less directly interested in the development and prosperity of the States and Territories in question—that the rainfall has materially increased since the advent of white settlers, and that this change is due to the trees which they have planted and to the breaking of the soil. That is to say, it is believed that small and for the most part widely scattered groves and belts of young trees—for the largest single plantation of trees in all the West does not exceed 650 acres in extent—and the ploughing up of a little land here and there, have been sufficient in a quarter of a century to alter continental climatic conditions.

The fact that several men of political and commercial position have recently undertaken to discuss the general question of the settlement of the Plains, has brought it again to public notice. It is an undoubted fact that in the past few years settlers have obtained a foothold considerably nearer to the eastern base of the Rocky Mountains than it was once supposed that crops could be raised without artificial irrigation. Mr. Henry Gannett of the United States Geological Survey in an authoritative article printed

in a recent issue of *Science*, shows, however, pretty conclusively that it is not an increase of rainfall that has modified agricultural conditions on the Great Plains, even if any such modification has really taken place. He has examined the rainfall records kept at twenty-six stations in Kansas, Nebraska, Colorado, Wyoming and Dakota, for periods ranging from six years to twenty-eight; the longest being that kept at Fort Leavenworth, Kansas. The stations are widely scattered from east to west in both the settled and the unsettled portions of this region. Mr. Gannett divides the results of these observations into two equal terms of years and adds the yearly rainfalls of each term separately. If settlement has increased the rainfall, the record for the years embraced in his second term should show the fact. The aggregate rainfall at all the stations during the period when the records were kept was in the first term of years 4,408 inches, and in the second term 4,468 inches, showing that there had been an apparent increase of 60 inches in the total rainfall, at all the stations, in a total of 310 years; or that 0.4 of an inch more rain fell in each year of the second than in each year of the first term—an increase which could not have made any perceptible difference in the agriculture of the region.

There is, however, no doubt, as Mr. Gannett suggests, that cultivation adds to the value of the rainfall. The surface of the Plains is naturally bare, compact, and but slightly protected by a covering of grasses. Water flows freely from such a surface and a large portion of the rainfall finds its way into the streams without permeating the soil. When the ground is broken up by the plough much more moisture is retained. The quantity thus retained increases from year to year, and the sub-soil becomes in time a reservoir from which the surface-soil draws moisture in times of drought. This is probably the true explanation of the fact that crops have matured on the Plains with a summer rainfall of only ten inches. But it must not be forgotten that the settlement of the Plains has been attended with great expense and with terrible suffering and loss of life; that in a region of such scanty and precarious rainfall any decrease in the amount during a single year must be attended with serious losses; that three or four succeeding years of drought must mean utter ruin to the farmer; and that the records long kept in other parts of the country show that such small variations are sure to occur with frequency.

The Study of Botany by Horticulturists.

ON three occasions after the late Professor Gray had given up the duties of college instruction, he was induced by the members of a Summer Course in Botany to deliver a few informal lectures. One of these, which can never be forgotten by the class in attendance, began in these words:

“You know the old and homely adage that ‘one-half of the world does not know how the other half lives.’ I may say that far more than one-half, even of intelligent people, do not know how they live themselves; they have only the dimmest and most vague notion of those arrangements in Nature, based on the vegetable creation, upon which their very living depends. And even if aware, in a general way, that plants nourish and support all animals, they do not know how it is done, nor have they the least idea of the beautiful harmonies that run through all plants, connecting one with another into a system, a symmetrical whole, a vegetable kingdom.”

Happily this censure is becoming less deserved than when these words were uttered. In our community there is an increasing interest in plants and in the laws which govern their growth and development. Much of this interest is due to the attractive manner in which Dr. Gray's educational works have placed before the American public the general principles of vegetable structure and life. And it is encouraging to observe that this interest appears to be

gaining ground not only among those who have abundant leisure for the examination of plants, but also among that large class to whom plants and flowers mean a livelihood. These latter having the requisite skill to turn their floral treasures to good account may sometimes plead their lack of time as an excuse for neglecting the study of the principles which underlie their practice. And, furthermore, it seems a formidable task to turn over the dry leaves of a text-book, when one has been working with fresh flowers all day, or has been planning picturesque landscapes with shrubs and trees and water.

In some countries a thorough study of the elements of botany is an essential part of the apprenticeship of an accomplished gardener, and such knowledge saves its possessor from many an error of judgment. Such acquisition is by no means so formidable a task as would at first appear, since a host of interesting and instructive elementary works is now easily accessible.

For one without a teacher, the task is not wholly free from difficulties, but none of these difficulties need be disheartening. A plain course designed to place any intelligent young person in possession of the more important facts and essential principles of elementary botany, might well begin with a thorough study of some such work as that noticed in our first number (Gray's "Elements of Botany"), and with the "Field and Forest Botany," by the same author. Let each point be illustrated from the living plants at hand, and let the main design of the two books be carried out fully—namely, to understand the plan of each flower, and to learn its relations to others. The mere ascertaining of the name of a plant in a convenient handbook is an easy matter, but if the easy work is well done, it brings out clearly many important features which might otherwise be overlooked. The study of the two books just mentioned ought to be supplemented by the collection and drying of such wild and cultivated plants as fall in one's way, making capital material for further study in the winter. In the "Elements," Professor Gray has given full directions for collecting and studying such specimens.

In the second season, the work should be somewhat wider in its range. With the "Elements" still as a guide, or sort of grammar, the student will begin to collect plants as before, but he will need some more comprehensive treatise, like the "Manual of Botany," for the determination of the wild plants collected; and now may be undertaken also the perusal of some volume like Bessey's "Botany," which will give much information regarding other plants than those which bear flowers. And, if possible, the student should now attempt to examine the minute structure or microscopic anatomy of the plants with which he deals. Either the "Manual of Plant Dissection," by Arthur, Barnes and Coulter, or the "Practical Botany," by Bower and Vines, will serve this purpose fully. The former is rather better for most of our American students, whose time is limited. Within the last year we have become acquainted with one young man who undertook a course similar in some respects to that here indicated, and the course had been successfully prosecuted under considerable difficulties. To that young man, the plants of his trade mean more than they have ever done before. Can it be thought that his skill in managing plants will be any the less for what he has learned regarding their life and peculiarities of structure?

For collateral reading while one is pursuing such a practical course as is here indicated, the following works are recommended: Le Maout and Decaisne's "System of Botany," "The Treasury of Botany;" works of travel, like Wallace's "Tropical Nature," Hooker's "Himalaya," Ball's "Marocco," Bate's "Naturalist on the Amazon," and the like. And, also, the charming and ever instructive works of Darwin, such as "The Power of Movement in Plants," "The Fertilization of Orchids," etc. From the wealth of interesting botanical reading, now brought within the reach of most horticulturists by means of the public libraries, it is easy to select trustworthy teachings, from which

those who get their living from plants may know in the fullest sense how the plants themselves live.

In horticulture—as, we are told, was the case in all other departments of human activity even so early as the time of the wise king of Israel—the novelties of to-day are apt to be merely the forgotten novelties of the past. A flowering Dogwood with pink bracts is now much talked of by nurserymen as something entirely new. But old Mark Catesby, a century and a half ago, found "one of these Dogwood trees with flowers of a rose-color;" and the tree having "luckily been blown down and many of its branches taking root," he was able "to transplant this variety into a garden." This garden was in Virginia where Catesby lived for a time, and a colored plate showing the pink-flowered Dogwood appeared in his work on the natural history of Virginia, Carolina and Florida, which was published in 1731 after his return to England.

Landscape Gardening—VI.

IN my preceding chapters I tried to explain the points of likeness and unlikeness that exist between landscape gardening and the pursuits to which we more usually give the name of Fine Arts. The explanation has been not only brief but fragmentary; but it will have fulfilled my purpose if it has shown with any degree of clearness that landscape gardening too should be called a Fine Art.

It remains now to ask, When and where do we need to exercise this art? The answer must be, Whenever and wherever we touch the surface of the ground and the plants it bears with any wish to produce an organized result that shall be agreeable to the eye. We must not be misled by the over-precision of our accustomed terms into thinking that art is needed only for the production of broad landscape effects. It is needed whenever we do more than merely grow plants for the sake of their beauty as isolated individuals. It matters not whether we wish to arrange a great park or a small city square, a large estate or a modest door-yard—we must go about the work in an artistic spirit if we want a good result. Two trees and six shrubs and a scrap of lawn and a dozen flowering plants may form either a beautiful little picture or a huddled little mass of greenery and colors. If it is the first, it will give us the truly æsthetic satisfaction we get from a good landscape painting—indeed, it will give us more than this, for the painted picture never varies, while the living one will reveal new beauties day by day with the changing seasons, hour by hour with the shifting shadows. If it is the second, it will please us only by the beauty of certain scattered details; and even these details will be intrinsically less delightful than had they formed part of an agreeable general effect. A good composition has been defined by Ruskin as one in which every detail helps the general beauty of effect; but it may also be defined, conversely, as one in which the general arrangement brings out the highest beauty of each detail.

The most cursory examination of any American town or summer colony of villas will show how deficient we are in artistic feeling when we deal with natural objects. The surroundings of our homes have improved by no means as rapidly as the homes themselves. Even in these we are far enough from having reached a general average of excellence. But we are on the right road, I think, towards its attainment. We have learned certain architectural truths, and we respect them theoretically, even though we may often err in their application. We do not expect to build a good house without an architect to help us; we do not expect him to begin without having a clear idea of the kind of house we want—of the special site it must occupy, the special needs it must fulfil, the special tastes it must meet; we are not content if he designs it by throwing together a number of pretty features without regard to harmony of effect; nor do we buy our furniture bit by bit as

passing whims dictate, and pile it casually about in our various rooms. At least there are not so many of us who do these things to-day as there were ten years ago; and all of us are well aware that they ought not to be done.

Yet they are just the things which almost every-one does outside his home. If he has "no taste for nature" himself, he puts his grounds into the hands of a gardener without inquiring whether he has any qualifications beyond a knowledge of how to make plants flourish. And if he has such a taste himself, it means, in a vast majority of cases, a mere love for being out-of-doors, for planting things, and for watching them grow. At the most, it is apt to mean no more than a taste for nature's individual productions—a love for trees, an interest in shrubs, a passion for flowers, or all these three together. The cases are very rare in which it means a taste at all analogous to what we understand by a taste for art; that is, an appreciation of organized beauty—of the beauty of contrasting yet harmonious lines and colors and masses of light and shade, of intelligent design, of details subordinated to a coherent general effect. Yet it is only such an appreciation as this which means a real taste for nature's beauty and which can make the surroundings of our homes really beautiful.

Of course, in this, as in every art, the "collector" has not only a right to exist, but an important rôle to play; but his is not the proper rôle to play when the adornment of one's home is the chief desire. When this is our desire, it is of far less importance what we have than how we have it. The quality of our plants is far more important than their quantity—and by quality is implied not rarity, nor even perfection of development, so much as fitness to the special places they hold in whatever general scheme may have been adopted. Composition, grouping, is the first great essential, even in a yard so small that shrubs must take the place of trees.

M. G. van Rensselaer.

Anglomania in Park Making.

WITHIN the area of the United States we have many types of scenery and many climates, but in designing the surroundings of dwellings, in working upon the landscape, we too often take no account of these facts. On the rocky coast of Maine each summer sees money worse than wasted in endeavoring to make Newport lawns on ground which naturally bears countless lichen-covered rocks, dwarf Pines and Spruces, and thickets of Sweet-fern, Bayberry and Wild Rose. The owners of this particular type of country spend thousands in destroying its natural beauty, with the intention of attaining to a foreign beauty, which, in point of fact, is unattainable in anything like perfection by reason of the shallow soil and frequent droughts.

I know too many of these unhappy "lawns." Ledges too large to be buried or blasted protrude here and there. They are bare and bleached now, though they were once half smothered in all manner of mixed shrubbery; the grass is brown and poor wherever the underlying rock is near the surface,—all is ugliness where once was only beauty.

Moreover, if the lawn were perfect and "truly English," how would it harmonize with the Pitch-Pines and Scrub-Birches and dwarf Junipers which clothe the lands around? No. The English park, with its great trees and velvet turf, is supremely beautiful in England, where it is simply the natural scenery perfected; but save in those favored parts of North America where the natural conditions are approximately those of the Old Country, the beauty of it cannot be had and should not be attempted.

To be sure, the countries of the continent of Europe all have their so-called English parks, but the best of these possess little or none of the real English character and charm. The really beautiful parks of Europe are those which have a character of their own, derived from their own conditions of climate and scene. The parks of Paulovsk, near St. Petersburg, of Muskau, in Silesia, of the Villa Thuret, on the Cape of Antibes in the Mediterranean, are none of them English, except as England was the mother of the natural as distinguished from the architectural in gardening. The Thuret park, if I may cite an illustration of my meaning, is a wonderland of crowded vegetation, of ways deep, shaded by rich and countless evergreens, of steep open slopes aglow with bright Anemones. Between high masses of Eucalyptus and Acacia are

had glimpses of the sea and of the purple foothills and the gleaming snowpeaks of the Maritime Alps. In the thickets are Laurels, Pittosporums, Gardenias, etc., from the ends of the earth; but Ilex, Phillyrea and Oleander are natives of the country, and Myrtle and Pistacia are the common shrubs of the sea-shore, so that the foreigners are only additions to an original wealth of evergreens. The garden also has its Palms of many species, with Cycads, Yuccas, Aloes and the like; but the Agaves are common hedge plants of the country, and strange Euphorbias grow everywhere about; moreover, the more monstrous of these creatures are given a space apart from the main garden, so that they may not disturb the quiet of the scene. M. Thuret saved the Olives and the Ilexes of the original hillside. He did not try to imitate the gardening of another and different country or climate, but simply worked to enhance the beauty natural to the region of his choice.

At the other end of Europe all this is equally true of Paulovsk. Here, at the edge of the wet and dismal plain on which St. Petersburg is built, is a stretch of upland naturally almost featureless, but which, thanks to a careful helping of nature, is now the most interesting and beautiful bit of scenery the neighborhood of the Tsar's capital can show. A considerable brook, in falling from the plateau to the plain, has worn in the gravel of the country a crooked and steep-sided valley, and this, the only natural advantage of the park-site, with its banks darkly wooded and the stream shining out now and then in the bottom, is the chief beauty of the completed park. The dead level of the plateau itself is broken up into irregular strips and spaces given to water, meadow, shrubland or woodland,—a pleasing intricacy. The grass is only roughly cut, the edges of the waterways are unkempt, the woods are often carelessly beset with Cornus, Caragana or Siberian Spiræa. In the woods are only hardy and appropriate trees—Oaks, Alders, Poplars, Pines and the like,—few trees are handsome enough to stand alone, but there are Spruces, pushing up through Scarlet Oaks, and White Birches set off against dark Firs and Prostrate Junipers spreading about Birch-clumps, and no end to the variety of similar thoroughly native and appropriate beauties. Here is no futile striving after the loveliness of England or any other foreign land; no attempting the beauty of a mountain country or a rocky country or a warm country or any other country than just this country which lies about St. Petersburg; here also is no planting of incongruous specimens and no out-of-place flower-bedding.

The park of Muskau teaches the same lesson, and under conditions closely resembling those of our Middle States. Indeed, American trees, shrubs and herbaceous plants are very numerous in this noble park; the Tulip-tree, Magnolia, Wild Cherry, Witch Hazel, Withe-rod, Bush Honeysuckle, Golden Rods and Asters are harmonized with native plants on every hand. It would be next to impossible to find an American park in which these things have been planted as freely.

Our country has her Russias, her Silesias, her Rivas; and many types of scenery which are all her own besides. Are we to attempt to bring all to the English smoothness? Rather let us try to perfect each type in its own place.

Boston.

Charles Eliot.

Conifers and their Cultivation.

IT is a point of theory that it is not safe to manure the land in which Conifers are planted, so that there will be any danger of bringing the fertilizer into direct contact with the roots; at the same time, I can affirm from the experience of many years, that every variety of this great and beautiful class of trees will prosper in a rich soil better than in a poor one, and in a soil that is moderately moist better than in one that is naturally arid. Yet it is true that when both coniferous and deciduous trees are planted in a very poor and dry soil the Conifers will be likely to do rather better than the others.

Most gardeners and cultivators of Conifers cherish the old English superstition that the great thing about a coniferous tree is its leader, the top shoot, which points directly upward and leads in the growth of the tree. If by any accident this shoot is broken off, they regard the plant as ruined; and if by accident, instead of one leader, there come to be two, the situation, in the opinion of these cultivators, is monstrous and without remedy. But, after many years' constant study and cultivation of Conifers of every kind—American, European, Asiatic—I am prepared to maintain that this superstition is even more absurd than the general run of such cranky creations of the human mind. There is no description of tree which stands the use of the pruning-knife better than the Conifer; and there is no part of a Conifer which

can more safely be cut off and thrown away than the leader. In fact, in the production of a perfectly symmetrical coniferous tree the first principle is the repeated extirpation of the leader. By removing it you throw the strength of the tree into the lower branches, and cause them to grow full, vigorous and beautiful. You need have no fear about the upward development of the plant. Nature will always provide a leader for it; and if you cut it off to-day, a new shoot will be there to take its place to-morrow. Some of the most beautiful Conifers that I have seen in the famous collections of England have been those whose leaders, notwithstanding all the care of the gardeners, have been broken off by storms, and whose general symmetry and vigor have been promoted in consequence. My practice in the treatment of these plants is to apply the pruning-knife constantly, though, of course, with judgment, and especially to keep down the leader.

Nothing is more necessary, however, than that the drainage of the spot where a Conifer is planted should be complete and unobstructed. A marshy spot, a stiff clay soil, or an impenetrable hard-pan near the surface, are all to be sedulously avoided. Every traveler who was in England thirty years ago will remember with delight the beautiful Douglas Firs near the nursery of Mr. James Veitch at Combe Wood. But a few years later they began to decline, and when I looked for them in 1886 they were gone. A dense hard-pan a few feet below the surface had done the business.

If my advice were asked respecting the sorts of Conifers which, for purposes of beauty and decoration, it is most advantageous to cultivate, the reply would be very much influenced by the facts of soil, climate, moisture and shelter from strong winds in the place designed for planting. No Conifers should be set out where they are subject to violent gales. They require shelter more than most kinds of deciduous trees. Our American White Pine especially illustrates the truth of this proposition, and so do the Canadian Hemlock and the Hemlocks of the Western coast (*Tsuga Mertensiana* and *T. Pattoniana*). The beautiful Japanese Hemlock (*T. Sieboldiana*) seems to stand the wind much better than either of its relatives. The Scotch Pine I am not able to praise in any respect except for its occasional transitory beauty, but the Austrian Pine, on the other hand, may be planted with confidence in its future form, color and duration, and especially in its power of resisting the wind; and on Long Island I have found it very useful as an outer shelter to protect more delicate kinds of plants against the gales. But this is a question of locality. At Castle Kennedy, in south-western Scotland—the most charming and enviable country-seat in the United Kingdom—they use for this purpose the exquisite and tender *Pinus insignis* of Southern California, which cannot be grown at all in our climate.

Next to the White Pine, the Canadian Hemlock and our common Juniper (*Juniperus Virginiana*), I have found the Red Pine (*P. resinosa*), the White Spruce (*Picea alba*), the Rocky Mountain tree formerly described as Menzies Spruce (*P. pungens*), and that beautiful Fir of the Rocky Mountains (*Abies concolor*), the most useful. With our Balsam Fir I have never been able to do much, because it needs more moisture than can be found anywhere except in a mountain elevation. *Pinus rigida* and *P. inops* I cultivate as a matter of interest, but without looking to them for any remarkable effects of beauty. The admirable long-leaved Pines of California and of the South are alike unavailable.

When we pass from the Conifers of our own hemisphere to those of Europe and Asia our resources are immensely enlarged. Among the most beautiful of these acquisitions the Retinosporas are to be classed as of the very first value. Similar to the Thuyas, they are more varied, more graceful and more lasting. In a soil of moderate moisture and in a year of reasonable rainfall, their growth and their color are lovely beyond description. Of the other Japanese Conifers *Abies brachyphylla* and the *Picea polita* seem to me the most valuable, while *Abies firma* should by all means be avoided on account of its irregular and shabby growth and its constant suffering from unfavorable weather both in winter and summer. *A. polita* is of exceedingly slow growth, but it stands every sort of climate, and when it is in perfect condition its color is delightful. *P. Orientalis* is also a treasure.

The Japanese Yew (*Taxus cuspidata*) is beautiful and hardy even in a severe climate, but its slow growth removes it from the category of plants for general and popular planting. The Cryptomerias are graceful and beautiful trees, and they grow rapidly, but they are not tough enough for our climate. *C. elegans* does not last out the winter, but *C. Japonica* will live with us, and I have seen it 70 feet tall on high land. Yet the frosts play the mischief with the lower branches, and it is no longer the fascinating plant whose charms bewilder every be-

holder. The *Glyptostrobus Sinensis* is much more available. Grafted on our ordinary southern Cypress (*Taxodium distichum*) it gains a height of 40 feet, and its slender, conical head and long, drooping foliage make it a most agreeable object.

I have had very fair luck with Yews and Cedars. With a very slight protection in the winter the Deodar flourishes in all its graceful beauty; but the Lebanon and the Atlantic are both of much slower growth and less graceful habit. The Atlantic, which comes from the mountains of Morocco, is much more hardy than the Cedar of Lebanon, though the latitude of the two regions is about equal.

Finally I have one piece of advice for the young planter, whether his purpose be æsthetic beauty or material profit; and that is, never to plant a Norway Spruce. One of the great misfortunes that have happened to the gardens and pleasure-grounds of our Northern States, is the introduction of this ugly and useless tree, which is never beautiful except in its old age; and even this beauty is so rare an accident that it forms an exception which no one can count upon beforehand.

Dosoris, March 15th.

C. A. Dana.

Wanted—A Hand-book of Horticulture.

THE number of manuals of horticulture in the English language is certainly very large, and yet it is not saying too much to assert that a really satisfactory work has yet to be written. An amateur wishing for useful information upon any point has usually to consult two, three or even more works before he can find all that he desires to know. The want of thoroughness in English works is familiar to all who use them, and by English works we do not mean only those which are published in England. Fortunately there is an excellent French work—the well known "*Fleurs de Pleine Terre*" of Vilmorin-Andrieux—which comes very near to the ideal treatise and is to be found in every good horticultural library. The third edition of this work was published without date upon the title page, but we believe about the year 1880. In 1884 a supplement appeared containing valuable additions, but still, as regards completeness, the work leaves something to be wished. What is in it is usually admirable and always to be depended upon, but the work is somewhat behind the times. The arrangement is alphabetical, the figures excellent, and the descriptions, as a rule, sufficient. In addition, however, to figures and descriptions, the work contains a rare amount of information upon horticultural topics generally most useful, and hard to find elsewhere. Thus, among other things very fully treated, we have a special list of seeds which may be planted in September; a selection of annuals and biennials; a selection of hardy plants; a selection of bulbous plants; a selection of plants for borders; a list of plants proper for carpet beds; a selection of climbers; a selection of fragrant plants, with a supplementary list of plants with fragrant stems and leaves; a selection of plants with ornamental fruits; a choice of plants with ornamental leaves in great variety and detail; a selection of hardy Ferns; a selection of aquatic plants, including several subdivisions, as, for instance, floating plants, submerged plants, half emergent plants, etc.; plants for rockeries; a list of plants growing in the shade; a selection of picturesque plants for lawns, and another of green-house plants which can be used for the open ground in summer; a list of plants for bouquets; a calendar of the seasons at which different plants flower; details of the arrangement of gardens, etc., etc.

The recent edition of Robinson's "English Garden" contains much valuable matter, and is deservedly a favorite in this country, but it is often very deficient in details and is not brought down to the date of its publication. German works on horticulture are very numerous, and it is hard to say which is the best, but here also the want of minute and careful detail is often keenly felt.

It seems worth while to consider what ought to be required in a good manual. In the first place, the alphabetical arrangement is certainly the most convenient. Now—given a particular plant—what the amateur and the educated florist wishes to know is, 1st.—the natural family, genus and species to which it belongs; its English or common name if it has one; the Latin name and its synonyms; 2d.—the character of the plant, whether perennial, biennial or annual, whether hardy, half-hardy or tender; 3d.—the exact description of the plant itself, with an estimate—not the salesman's estimate—of its precise horticultural value under appropriate conditions; 4th.—the country in which it, or the species of which it is a variety, is found growing naturally, and especially the natural conditions of its healthy growth as regards soil, climate, exposure, dryness

or moisture, sunshine or shade; 5th.—the details of its successful culture, with the experience of prominent horticulturists, given with thoroughness and critical knowledge; 6th.—any peculiarities which the plant may exhibit, bearing upon its reproduction, upon the probability of obtaining varieties from it by seed or by hybridization, with suggestions for trial; and 7th.—the advantages and disadvantages which the plant offers to the amateur of limited means and limited knowledge.

All amateurs know that in the annual catalogues of florists the merits of a plant are always very strongly and not always very truthfully stated, while its demerits are passed over in silence. Yet these last may be and often are of much greater importance. Let us have the whole truth about every plant, and have it in detail. One bulb about which nothing is said but that it yields a brilliant flower, does yield such a flower, lasting for an hour or two only. Another much lauded plant requires such an amount of care and attention—such coddling and nursing—as to make its culture, to say the least, very undesirable for most lovers of plants. A third blooms so late in the season, that in cool climates—upon the sea shore, for instance—it never yields a flower, or blooms only to be cut down by an untimely frost. Another requires a heavy covering of leaves in the autumn, to be removed at a certain time in the spring and with certain precautions. Now, what the amateur has to complain of is that no one work gives all that he wishes to know before purchasing a particular shrub, bulb or package of seeds, so that he can at once tell whether it is advisable to attempt the culture of what seems in the salesman's description so attractive. During the last twenty years a great deal of valuable experience has been gained in regard to the culture of plants in the open ground, and a large number of new plants has been introduced. The volumes of the *Gardener's Chronicle*, *Garden*, *Gartenflora*, *Revue Horticole*, and other periodicals, contain an ample supply of material at least for the purely practical part of a complete manual of horticulture. Some old books—Mrs. Loudin's quarto volume on bulbs, for instance—are not yet out of date, and contain some very valuable information not to be found in more recent works or not with the same amount of detail. Why should we not have a work on plants for the open ground, which should be made up of a series of brief but complete and thorough monographs giving all that is known about each plant? Plants which require to be wintered in cold-frames or green-houses should of course be included, but green-house plants proper, vegetables and fruits, should be omitted, because all these require special treatises. We should still have a large and probably somewhat expensive work, but one which would replace a library of other treatises—but the names of the best plants and best varieties need be given and only the best authorities cited. Ornamental shrubs could be admitted into such a work, but not trees, properly speaking. For these there should be a special treatise written upon the same plan. Such a manual as is here proposed might be the work of a number of writers, each taking a particular class of plants—a committee, for instance, of some prominent horticultural society. Properly divided among various co-laborers, the work could be finished in a comparatively short time. Figures are not absolutely necessary, though often convenient and sometimes very desirable, but they would greatly increase the expense of the work if numerous. It is possible that a good translation of Vilmorin's work, with the permission of the author, might serve as the basis of a new and greatly enlarged treatise. We want the experience of all the leading amateurs as well as of the professional gardeners, and we want a work which shall be a complete manual written in the highest scientific spirit, to be improved, added to, corrected and condensed as new editions may be demanded.

Newport, R. I.

Wolcott Gibbs.

Phlox adsurgens.*

MOST of the eastern species of *Phlox* have long been favorites in the gardens both of this country and of Europe. The ease with which they are cultivated, the abundance and long continuance of their flowers, and the variety of their coloring will account sufficiently for this. The tall perennial species, with compact inflorescence, and in numerous varieties, the annual Drummond's Phlox, with its looser, profuse bloom of manifold colors, and the evergreen Moss Pink, covering the soil in early spring with a carpet of flowers, are all equally well known. On the other hand, the species of the

**P. ADSURGENS*, Torr. in herb.: Gray, *Proc. Am. Acad.*, viii. 256. Glabrous, with the slender peduncles and calyx glandular-pubescent; stems about a span high, ascending from a procumbent base; leaves ovate or ovate-lanceolate, acute; corolla-tube more than twice the length of the short calyx, the segments of the rose-colored limb obovate and entire; style elongated.

Fig. 11.—*Phlox adsurgens*.

western part of the continent are totally unknown as ornaments of the garden. Most of them differ in habit from their eastern relatives, some being dwarf perennials, forming compact evergreen cushions, which in earliest spring are a mass of color, and the rest loosely tufted plants, with an open, rather few-flowered inflorescence. On the whole they do not promise to prove so valuable to the florist as are the eastern species, but skillful treatment may develop strains that will repay the trouble of trial. *P. nana*, which in the wild state varies greatly in color, *P. adsurgens*, and some of the caespitose species, are certainly not without merit.

Nearly all have narrow, or linear, or small and awl-shaped leaves, the only one with broader leaves, like most of the eastern species, being the one of which a figure is here given. This, *P. adsurgens*, is a rare species of the Cascade Mountains

of Oregon, where it was first collected by Professor Alphonso Wood in 1866. It has since been found by Mr. Cusick and Mr. Howell, and also by Mr. V. Rattan in the mountains of north-western California, in Humboldt County, growing on high ridges in the Fir forests. Its characteristics are well shown in the figure, —, its slender, ascending stems, ovate leaves, open, graceful inflorescence and long-tubed corollas. The flowers are rose-colored, appearing in July and August. S. W.

lateral branches of the year. Rarely more than a single fruit matures from each corymb of flowers; it is oval or obovate, hardly exceeding one-third of an inch in length, long pedunculate, and bright scarlet in color. The autumn color of the leaves is a brilliant scarlet.

Photinia villosa is a valuable addition to the free flowering and perfectly hardy shrubs which can be grown in the northern States. It was sent many years ago to the Arnold Arboretum

Fig. 12 —Photinia villosa.

Photinia villosa.*

THIS is a widely distributed and very variable Japanese deciduous shrub which, according to Maximowicz, sometimes attains in its native country a height of 15 feet. *Photinia villosa* (fig. 12), as it appears in cultivation in this country, is a vigorous shrub of neat habit, 4 to 6 feet in height, with broadly obovate rather coriaceous, sharply serrate, dark-green leaves 1½ to 2 inches long with prominent mid-ribs and primary veins, their under side, as well as the young shoots, petioles, peduncles and calyx, covered with a dense white pubescence. The corymbs of white flowers, which appear about the middle of June, are terminal on the short

by the Messrs. Parsons, of Flushing, under the name of "*Amelanchier* sp. from Japan." C. S. S.

Cultural Notes.

Epidendrum (Nanodes) Medusæ.—This is a somewhat rare and most singular looking Orchid, producing tufted, pendant stems about a foot long, with very fleshy grayish leaves arranged in pairs on each side. The flowers (usually 2-3) spring from the axils of the last pair, are flat and fleshy, sepals and petals are purple with a green base. The lip is large and spreading, deep maroon, transparent, and deeply fringed. It is a native of the mountainous regions of South America, consequently requires to be kept very cool. We succeed here admirably in a uniform temperature of 55° to 60°, with abundance of water, and if this is given overhead the thrips will not trouble it. Until quite recently this plant was very rare and large house grown plants are still the exception.

**Photinia villosa*, DC. Prodr. ii. 631.—Miq. Procl. 229.—Fran. & Savat. Enum. Pl. Jap. i. 142; ii. 351.—Maxim. Bull. Acad. St. Petersburg, ix, 176.

P. serrulata, Sieb. & Zucc. l. c. (not DC.)
Pourthiaea villosa, Decn. Nouv. Arch. du Mus. x, 147.

Cœlogyne cristata alba (hololeuca).—This rare albino is now in flower with us (a plant with seven spikes). It differs from the type simply in the absence of the yellow of the lip, thus rendering it the only instance, I believe, of an entirely pure white Orchid. Though very rare at present, it is like the type—such a free grower that it cannot fail to be plentiful before long.

Sarcochilus (Thrixspermum) Berkeleyi.—This charming little rarity belongs to the caulescent section of Orchids and in general appearance is not unlike a miniature *Erides*. The drooping spikes, which are about eight inches long, are thickly set with white flowers with but a dash of amethyst on the lip. The curious sac-like appendage, from which the genus takes its name, renders the flower very remarkable. This species grows well with us among the *Phalænopsis*, in a basket filled with crocks and sphagnum moss.

Bertolonia marmorata.—This is a charming little ornamental leaved plant belonging to the Melastoma family and is valuable for mixing with Ferns in the green-houses. The leaves are 5 to 8 inches long and half as broad, of a bright green beautifully streaked with pure white, while the under surface is of a rich purple. It luxuriates in a warm, moist atmosphere in a shady corner. A compost of loam, peat and leaf mould with a good sprinkling of sand in well drained pots suits it. When they lose their bottom leaves the plants should be taken out and repotted into small pots, sinking the stem as low as possible, so that the new leaves will cover the pot. Keep the plants comparatively dry until they get nicely rooted, after which they should never be allowed to become dry. It was introduced from Brazil in 1858.

Rondeletia (Rogieria) gratissima.—This Mexican shrub bears corymbose cymes of pinkish fragrant flowers. We find that it blooms during nine months of the year, and grows best in a cool green-house temperature, and in a mixture of two parts loam to one of peat. To encourage growth we plant it out in the open ground during the summer months.

Amaryllis Aulica.—A few large plants of this good old species are in bloom with us now while others are being retarded in the cold house. Most of the bulbs are bearing two spikes each and some of the pots contain 15 to 20 bulbs. This species is evergreen, and need not be repotted more than once in 3 to 4 years, but may be fed with liquid manure during active growth.

Phalænopsis Sanderiana.—Some plants of this grand species now in bloom here show a great variation both in the flower and in the leaf, scarcely two of them being alike. The most attractive kind has the flowers suffused with a delicate rose, which is much darker on the upper section of the flower. This kind is almost invariably found to have leaves marbled as in *P. Schilleriana*, while the pale varieties possess the green leaves of *P. amabilis*. Among the best of the paler kinds is that called *P. marmorata*, in which the lateral sepals are much spotted with purple. The lip also is beautifully stained and spotted with the same color. It has been suggested that this species is a natural hybrid between *P. Schilleriana* and *P. amabilis*, and the great inconstancy in the color of the flowers and leaves tends to strengthen this theory. Some of the plants when out of flower cannot be distinguished from *P. Schilleriana*, and others from those of *P. amabilis*. *P. Sanderiana* was introduced in 1883 from the East Indian Islands. It grows well with us in a warm, airy house, potted in cylinders or baskets which are nearly filled up with broken crocks, and with a thin layer of sandy peat on the top. Abundance of water should be given at root and overhead during the growing season. When at rest water should be given freely at root, but the atmosphere should be moderately dry. During this period a minimum temperature of 60°, with a rise of 10 to 20° according to the weather, will suit them.

Calanthes which have finished flowering should be kept dry, in a temperature of about 60°, until the new growths begin to emit roots, when they should be shaken out of the pots, the old roots nearly all trimmed off, and repotted in fresh soil, which may consist of two parts fibrous peat, one of loam and one of half-rotted leaves. Water should be given very sparingly until the plants are nicely rooted, after which they need plenty of water and strong heat, with an occasional syringe overhead. After the plants are pot-bound, weak liquid manure may be given them nearly every day.

Phalænopsis Harriettis.—This is one of the latest additions to this lovely genus, and was produced by the intercrossing of *P. amabilis* with *P. violacea*. It is the most handsome and striking of the whole genus. The habit of the plant, size and form of flowers form an intermediate character, but the spike is that of *P. violacea*, but more slender. The flowers are greenish-white, suffused and dotted with rich, rosy purple, which becomes more intense and is in bars near the base of sepals and petals. The lip is of a rich, velvety purple, with yellow at base. This is the second time only that this species has flowered, and with the increased strength of the plant, there has been a wonderful improvement in size and color of the flowers. This we have also found to be the case with the artificial hybrid *P. intermedia*, which is now far superior to any imported natural ones.

Kenwood, N. Y.

F. Goldring.

Freesias.—These are the best of all our winter-blooming bulbs; they are of the easiest possible cultivation, bloom abundantly, and the flowers are fragrant and beautiful and have a refined appearance, without any of the coarseness peculiar to the "Dutch" bulbs. The best of all is *F. refracta alba*; *F. Leichtlini* is also common in cultivation, together with hybrids between these species. "Dutch" bulbs if forced this year are almost worthless for further use; Freesias on the contrary improve and multiply year after year. Growers for market plant the bulbs thickly on benches, in about four inches deep of soil; private growers raise them in pots. By having them in pots we can have them in bloom in successional groups for some three months in winter. Any good rich soil—turfy loam and rotted manure—suits them very well. A dozen bulbs in an eight-inch pot will give capital flowers. Pot in August or September, and keep them cool but away from frost, and let them come along slowly. We can force them into bloom by introducing the most advanced plants into warm quarters. After they have done blooming keep them growing as long as the foliage keeps fresh and green; when it begins to fade dry off the plants and keep them dry till potting time next August. The finest Freesias I ever had were grown for two years in the same pots and without repotting. And this year in order to have as good next year, when the plants were coming into bloom I repotted them into larger pots, taking care not to break the ball of roots; this did not interfere with their blooming at all. They are also easily raised from seed. A few of the plants raised from seed sown this spring may bloom next winter, but the majority of them will not bloom till the following year.

Hydrangea rosea.—This is a comparatively recent introduction from Japan, and in flower and foliage distinct from the older *Hydrangeas* of our gardens. It is equally available for outside and inside work, and with a mulching in winter will live out-of-doors; if the bushes are killed down to the snow line, the shoots from the bottom will grow up in quantity and bloom in summer. This is not always the case with the common *Hydrangea*, for north of New York, if it be killed to the ground in winter, the young shoots from the bottom, although they grow large and vigorous enough, seldom bloom well, often not at all. *Hydrangea rosea* blooms some two to three weeks earlier than does the variety known as Thomas Hogg, and this is more marked when it is forced than when grown out-of-doors. Cuttings of the young wood strike with the greatest freedom. Although the proper color of the flowers is a pretty rose, they often assume a bluish tinge.

Chinese Primroses.—Sow at once if you wish for good plants for Christmas; plants for Easter may be sown in summer. Mixed seed as a rule is unsatisfactory; far better pay a little more and get exactly such colors as you want; the poor varieties require just as much room and care as do the fine varieties. *Alba magnifica*, white; *Meteor*, bright red; *Chelsea Rose*, pale rose; and *Chelsea Blue*, are most excellent varieties. There is a good deal of emphasis laid on fern-leaved varieties, but their flowers are no better than those of the rounder-leaved sorts; indeed there is not a pronounced difference between them. Chinese Primroses should be kept in active growth, moderately moist and slightly shaded all the time, and as cool as possible during the summer months. As the single varieties can be grown so easily from seed it is not worth while to save over any of them for another year. But as the double flowered sorts are uncertain from seed we should keep them over and propagate them from cuttings in the same way as is commonly done with the old Double White. W. F.

Trial Beds.

THIS is the season of catalogues. Every year they become more sumptuous and alluring with their long lists of novelties. Some are already illustrated horticultural magazines, and if the evolution continues we shall eventually have morocco-bound annuals distributed through the mails. The catalogue of to-day is a tribute to the growing taste for horticulture. The shrewd, experienced money-maker from the soil knows how to discount these large and much-embroidered promises of a renewed Garden of Eden. He turns straightway to the old standard, established sorts, and invests in these alone. His calculating eye is fixed on a crop that will pay beyond the shadow of a doubt. He is right, and so may you and I be right if we take a different course. That crop pays best which yields what we value most. There is a solid satisfaction in a fair return in dollars and cents from our land, and it is well to aim at this. The farming which makes milk cost as much as champagne, the vegetable garden which suggests to the natives only the color of the bank-notes expended, tend to confirm in many minds the idea that the methods of their grandfathers were the safest and wisest. But lavish, ignorant expenditure is a very different thing from a continuous course of experiments which need cost but comparatively little. For our own sakes, and especially for the sake of our children, we would seek to banish the hum-drum element from rural life. In no other pursuit have we such opportunity to do this as in horticulture. Let me give at once practical illustrations of what I mean. Here is a plot of ground. You can put it all in a crop which an ignorant laborer can take care of. You can also put the soil in fine order this spring, select from a catalogue a dozen or more of the most promising varieties of peas, say; plant them all at the same time and under the same conditions, the dwarf kinds by themselves, close together, those requiring the support of brush farther and farther apart, until you come to the unrivaled old Champion of England. Now you have a play-ground as well as a pea-patch for yourself and all the family. You will soon need a little recording note-book with a page allotted to every carefully labeled kind. The children will be glad to go with you often to see which sort first pushes through the soil and then to watch the race on through blossoming to maturity and the table. The entire family will discuss the comparative flavor and merits of the varieties, all kept on the *qui vive* over that pea-patch for several weeks. Bright-eyed boys will be almost as willing to work in it as to go fishing. The careful record kept from first to last will reveal which kinds are earliest, which the most productive and profitable to raise, and which the best flavored. May not such a crop be worth far more than one stolidly raised and stolidly sold or eaten? The outlay need be small indeed, but the return is that which makes life—zest and enjoyment.

Take another inexpensive yet more extended method of amusement and experiment. Select a strip of ground as long as you please and about fourteen feet wide. Enrich it well with manure from the cow-stable, if possible, but any fertilizer will answer, so that it be not too fresh and liable to ferment. Mix the fertilizer evenly to the depth of eighteen inches, and then set out as many varieties of strawberry plants as you can afford space for. Let the rows be two feet apart across the bed, and the plants one foot apart in the rows. By this course you will have a dozen plants of a kind in every short row. Label carefully, and begin your written record. Now you have a trial bed that will last three years at least. In May, the April-set plants will begin to blossom. Pick off the blows as fast as they appear. The small amount of fruit produced the first season is of no value, but a great injury to the young plants. Letting them bear is like working a colt. In June the young plants will begin to throw out runners and the tendency will increase till fall. Nature's law of propagation is working; but it is fruit, not plants, that you wish. Therefore cut off every runner as it appears—an easy task for children. Force every plant you set out to grow as large as it will on its original root. If plants die, merely permit sufficient runners to grow to fill their places. Since the plants are allowed neither to blossom, bear nor produce runners, there is only one thing they can do, and that is, to grow into great bushy stools and develop fruit buds for the ensuing year. By fall you may find that a peck measure will scarcely cover a plant. Of course the hoe should be kept busy throughout the season. But little hand-weeding will be required, because the plants have not been allowed to run and mat together. Clean, frequent culture is absolutely essential to the best results. As soon as the ground begins to freeze in the autumn cover the plants well, but not deeply, with light stable manure, leaves, litter of any kind not full of noxious seeds. Uncover after the alternate freezing and thawing of spring is

over, rake off the litter as soon as the ground is dry enough to work, then fork the soil lightly between the plants and return the litter as a mulch, adding enough more to cover the ground evenly. When I say, fork the ground lightly as soon as it is dry enough to work in early spring, I mean just what I say. I do not say, let a stupid or careless workman half dig the plants out when loosening the soil, nor do I suggest that this work can be done just as well late in spring after the plants begin to blossom. Many authorities declare the ground about bearing plants should not be disturbed in spring till after the crop has been produced. I have always found cultivation advantageous if performed when and in the way I have indicated, but not otherwise. If space permitted, I think I could support my opinion with good reasons. After this very early cultivation the plants are ready to bear. The mulch around them should be sufficient to keep the ground moist and the fruit clean.

Soon comes the exciting period, when the berries change from green to white and then begin to blush in the June sunshine. Careful notes should have been made all along as to the comparative vigor of varieties, hardiness, time of blossoming, character of blossoms, etc. Now the record should be full indeed as to size, productiveness, firmness of the berries, and, above all, as to flavor.

The differences in fully matured and ripened strawberries would astonish those who have always purchased their supplies in the market.

A strawberry bed, treated as I have described, is "a thing of beauty" and would be "a joy forever," if it could last. It does last three times as long as the ordinary matted bed of two or three varieties, and the fruit averages three times the size. We have had Crystal City strawberries in May, and Memphis Late and Triomphe de Gand berries after the 4th of July.

What a delight to visit the trial bed every day—see each variety developing after its own organic law! The entire family becomes a tasting committee, and the children learn from delicious experience the infinite opportunities afforded by horticulture to gratify higher tastes than those of the palate. The beautiful fruit, large and perfectly developed by high culture, pleases the eye as well; the variety in form and flavor, the different aspects of plants and foliage, suggest that similar tests may be applied to other fruits, to the whole range of flowers, vegetables and ornamental shrubbery. In brief, the reason becomes apparent why man was first put in a garden, for therein are found the varied interests which continue to our latest age as fresh and undying as Nature herself. In our large cities are multitudes of pallid, dissipated youth who might have been kept in breezy country homes if the stolid, plodding element had been eliminated. Those crops often pay best which nourish mind as well as body.

Cornwall-on-Hudson.

Edward P. Roe.

Foliage With Cut Flowers.

A careful study of the place and manner of growth and of the tone and character of the foliage of any plant will suggest the most effective arrangement for the cut flowers of that plant. To illustrate, the Gladiolus is always an aggressive and striking flower no matter how delicate it may be in shade. Its function seems to be to enliven by its bold display of color. Its foliage is a dull but strong green and is linear in form. Following this suggestion, we find it appears to best advantage when its spikes are arranged in a tall vase with a liberal use of the long leaves and stems of the various giant Grasses or Sorghums or even of Indian Corn. The forage plant called "Tiosinte" is particularly good for this purpose.

The common white garden Lily throws its cluster of dazzling white flowers well into the air, supported by an almost leafless stem, and we never have been able to arrange effectively any foliage with this flower. The white is so intense and yet so delicate that it needs no aid and is injured rather than helped by any other color. The only flower we have ever seen effectively arrayed with this is the Agapanthus. Its flowers are in their way as delicately beautiful as those of the Lily and blend well with them.

Nothing will bring out the beauty of blue Larkspurs like well matured Carrot leaves, and a comparison will show that in color and expression they are much like the natural foliage of the plant. In the same way clusters of wild or seedling Pear leaves form the most effective setting for the brighter colored Roses.

To extend these illustrations a little further, arrange a basket of Concord Grapes with Delaware foliage and one of Delaware with Concord foliage, and then another plate of each with its own leaves, and observe the more pleasing effect of the latter.

I have found a vase made as follows admirably adapted for the natural arrangement of such flowers as *Gladiolus*, and, in fact, for all strong growing kinds. Take a smooth and perfect length of common 6 or 8 in. stoneware sewer-pipe, paint it a pleasant neutral tint; have fitted into the smaller end a tin can some 8 inches deep and supported by a flange projecting over the top. Have a tinsmith make two circles of wire fitting easily into the can and have these circles filled with cross wires so as to make a net work of about an inch mesh. Solder to these circles—and in such a way that one of the circles is held about two inches from the bottom of the can and the other just below the top—two stout wires bent like the bail of a pail, and of such length that when the circles are in place the arch of the wires will be some 6 inches above the can and cross each other at right angles. The two circles and the upper wires will enable one to place a spike of *Gladiolus* or a spear of grass or any long stemmed plant so that it will retain just the place in the arrangement that may be desired, while by means of the wire handles the whole arrangement can be lifted out of the can to remove the water when necessary.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—I was glad to see, in a recent number of your paper, that you had called attention to *Boronia megastigma*. The delicious fragrance of its flowers certainly entitles it to more general cultivation in our green-houses. But there is another plant, equally fragrant, which one seldom meets with nowadays—not nearly so often as thirty years ago. This is *Mahernia verticillata*, a half-shrubby or woody perennial, introduced from the Cape of Good Hope about 1820. In habit it is not so attractive as *Boronia*, growing in a rather straggling way. But its flowers are prettier—small, bright yellow bells, profusely produced and as sweet as Lilies-of-the-Valley; and it is also a much freer and more rapid grower and one of the easiest of all plants to propagate. In a cool green-house it will bloom throughout the winter and spring, and it is one of the very best of house-plants. I should think it would be an excellent plant for florists to grow for winter sale in pots—in flower for room-decoration—as it remains so long in blossom and its delicious odor will permeate a whole apartment. *Mahernia* may also be had to flower out-doors in summer, and when I was young it was commonly grown in vases and hanging-baskets, a purpose for which its habit renders it peculiarly suitable.

Elizabeth, N. J.

W. J. K.

[Our correspondent does not say too much in favor of this plant. It is not rare in old green-house collections in this country, and a writer in a recent issue of the *Gardener's Chronicle*, of London, lamenting that it has "long been lost to English gardens," states that good plants can be purchased in this city for 30 cents a piece.—ED.]

To the Editor of GARDEN AND FOREST:

Sir.—What Mr. Parkman said in No. 1 of GARDEN AND FOREST of the White Mountain forests as capable—with proper treatment—of furnishing a steady supply of timber, and of the serious injury to the business of summer resorts and to manufacturers if speculators should cut off these forests, is applicable to many other parts of New England. In Berkshire County, Mass., White Pine comes up readily and makes a strong growth, but is not cared for so as to make straight, first-class timber. In this town about a million feet of lumber are cut every year, and at least half of this is white pine. It is, however, only fit for box-boards and on the stump is worth some \$4.00 per 1,000. Meantime the population is steadily decreasing, deserted farm houses staring one in the face on every road. There is not enough profitable occupation for even the few who are left, and the most enterprising young men seek business elsewhere. Here and there, however, one sees a grove of thick-standing, tall and straight pine trees, proving that good and high-priced lumber (and much more of it per acre) can be grown whenever it is protected and a little pains taken to secure a thick stand. It would prove an instructive object-lesson if some one would take and sow Pine on one of these farms in with whatever hoop-pole stuff will thrive best. The first crop of poles should be cut close to the ground so as to promote sprouting (*vécepage*, as the French call it), and continuous harvests of them should be taken off the ground until the Pine begins to shade and crowd the hard wood. After that thinning will be all that is required, and the material yielded by it will pay for labor, interest and taxes. When the feasibility of

this is once demonstrated, there will no doubt be plenty of imitators, and the tide of population now ebbing so sadly will flow back toward these noble hills.

Otis, Mass.

S. W. Powell.

The Forest.

The Forest Vegetation of Northern Mexico.—I.

THE tourist, who, fresh from a ride through the densely wooded swamps of Arkansas or Louisiana, or from the Pine-covered heights of New Mexico, enters Old Mexico at Paso del Norte, and mounts by night from the valley of the Rio Grande to the central tablelands, where in a journey of a thousand miles towards the capital he sees apparently but naked plains and bare and serrated mountains (notice in Spanish the same word, *sierra*, for a mountain range as for a saw), would doubtless be surprised at my choice of a theme for these articles. Nevertheless I have something to say of forests and forest trees in that same region, but more concerning the forests covering the Cordilleras, which lie from one hundred to two hundred miles west of the central railroad.

The tablelands of central Mexico, mostly covered by the States of Chihuahua, Coahuila, Durango, Zacatecas and San Luis Potosi, are plains, lying at an elevation of 4,000 to 7,000 feet, interrupted at intervals of ten to twenty miles by broken ranges of mountains, whose summits are 2,000 to 3,000 feet above the surrounding plains, or 6,000 to 9,000 feet above sea level, and whose trend is south-east and north-west. In the State of Chihuahua these mountain-bearing plains ascend from the Valley of the Rio Grande on the north-east, less than 4,000 feet elevation,—in the State of Durango from the Laguna country on the east, a region of lakes which are river sinks, and less than 4,000 feet altitude—and culminate in the continental divide lying within but near the western bounds of these two States. Where the divide is a gently swelling plain, as immediately north of Cusihuiriachic, its altitude is about 7,000 feet; whenever it rises to a mountain crest it attains an elevation of 8,000 to 10,000 feet. It is doubtful whether along all the mountain line that stretches southward from the United States boundary a greater elevation than 10,000 feet is to be found, until we come to the snow peaks which look down upon the valley and city of Mexico.

To the west of this divide, parallel with it, but not always contiguous to it—for in some places the Pacific Slope begins with a broad, gently falling plain—lies the Cordilleras region of north Mexico, a belt seventy-five to one hundred and fifty miles wide, closely packed, forest-covered mountains; cut through everywhere by torrents in swift descent to the lowlands of Sonora and Sinaloa—torrents which have formed a labyrinth of gulches, cañons and barrancas, the terror of the traveler—rising higher towards the west only in the seeming, because there the valleys are deeper; in the upper or eastern portion of the belt narrow, habitable valleys at rare intervals only, but more frequent and broader valleys, as we descend towards the *Tierra Caliente*, showing villages, grain fields and Orange orchards. On the cool, evergreen heights of this western verge of the plateau is condensed the moisture borne inland by the winds of the Pacific. So a good measure of rain and snow usually falls here during winter; while from July till August thunderstorms are of daily occurrence. The storms of winter being almost wholly lost among these mountains, the interior, however, is left comparatively rainless from October to August; for, so slow is the eastward progress of the summer rains, preparing their course step by step over successive mountain chains and heated plains, that it may be as late as August ere they descend to the valley of the Conchos, and meet in its vicinity the rains from the Gulf of Mexico, also retarded in their inland march by the similar barrier presented by the Sierra Madre of eastern Coahuila and San Luis Potosi.

But it is not due to dearth of water alone that the interior plateau remains comparatively bare of forest growths. The explorer everywhere observes in that region a paucity of soil, because, chiefly, it has never had the benefit of glacial action to grind down the rugged mountains and strew the resulting earth over the land in deep and fertile drift formations. Moreover, the action of frost to disintegrate rocks, and bring down the toppling crags, is there exceedingly slow, since water to aid in its operations is generally withheld in winter. So the mountains do not possess sufficient depth of soil to carry through eight to ten months of drought the water supply necessary to the life of a forest. By May, in fact, whoever travels them incurs risk of perishing by thirst from inability to find a living brook or spring. Therefore the trees of all the interior ranges are thinly scattered and of stunted growth. In the

extreme drought of last April I saw them putting forth new leaves but feebly and shedding their flowers without ability to set fruit. Only in the cañons, where they may be somewhat protected from the fierce heats by overhanging cliffs, and where deposits of soil may lie, can they attain full size, or can the species with broad, thin leaves exist.

Not less are the plains unfavorable to tree growth. In a former age of the world they were covered with inland seas. Some of these broke through their mountain dykes and emptied themselves into the Gulfs of Mexico and California; the others have nearly dried up under the sub-tropic sun. Except in their lower basins, there was deposited on their gravelly bottoms but a comparatively thin layer of fine earth; and as a peculiar feature of common occurrence, before this thin deposit was laid, the gravel was cemented together by an aqueous deposit of lime washed down from neighboring hills. The dry slopes and mesas resulting from this now bear of ligneous vegetation only a few peculiar shrubs, which may be described hereafter.

C. G. Pringle.

The Forests of Tunis.

THE following interesting account of the forests of Tunis, recently issued from the British Foreign Office as a Consular Report, is reprinted from the *Gardener's Chronicle* of London.

"The forests of Tunis, which cover an appreciable part of the surface of the country, were, until the French occupation, subject to no supervision, and suffered from the want of that supervision. In 1883 the French, alive to the importance of preserving what remained of these forests, which are the property of the State, placed them under the management of a separate department, which has explored their extent and demonstrated that they are an important element of national wealth.

"The explorations have resulted in the division of the forests into two main groups; one consisting of the Cork tree and deciduous Oak, locally known as 'Zen,' covering the north-western angle of Tunis, where it abuts on the Algerian frontier and the sea, and separated from the rest of Tunis by the river Mejerdah. These trees grow in a stratum of sandstone, which again reposes on the upper chalk, and they completely disappear where the latter stratum crops to the surface. They cover an area of about 360,000 acres, on 330,000 of which flourishes the Cork tree, and on 30,000 the 'Zen.' It is found that the former invariably grows on the southern slopes of this mountainous region; and, on the northern slopes and in the hollows of valleys, the latter.

"South of the River Mejerdah both these trees disappear, and give place to the Pine and a species of evergreen Oak. They are scattered in groups over various mountainous regions of no great elevation, all comprised in the northern half of the Regency, where alone the rainfall is sufficient to sustain their growth. It is calculated that these several forest groups cover a surface about equal to that covered by the Cork trees and 'Zen,' viz., 360,000 acres.

"These latter groups are in a more neglected state than the former. For the most part they are nearer to important towns than the Cork forests, and from time immemorial have supplied those towns with fuel. The bark of the Pine is also used for tanning and coloring hides and skins; and as no control is exercised over the cutting down of the trees, or stripping them of their bark, and goats are allowed to roam everywhere, the forests are rapidly deteriorating. No legislation has as yet been adopted for putting a stop to this waste, and though the Department of Woods and Forests proposes that the chiefs of the contiguous villages and tribes should be held responsible for the depredations, the Government has not yet ventured on this high-handed measure.

"It is to the Cork forests that the attention of the new administration has been mainly directed. They are situated in a country with a very sparse population, dwelling in huts formed of the branches of trees. Their number is estimated at 18,000 souls, or only one individual to 30 acres. It was open to the French administration to adopt one of the three following systems in dealing with the woods and forests, viz., their sale, their concession for fixed periods, or their management by the State. The last was chosen as the system best adapted for their preservation and extension, particularly as it was held to be of paramount importance to favor the increase of rainfall in the country, the quantity of which is supposed to be intimately connected with the extent of the forests. That they were more extensive in the time of the Romans, and that they conduced to augment the annual rainfall, may be inferred from the discovery of numerous aqueducts among hills which are now absolutely denuded of trees and destitute of springs.

"Much has been done during recent years in improving the condition of these Cork forests. Roads have been cut through them, and at stated intervals spacious alleys have been frayed to serve as a means for arresting the march of the fires which frequently ravage them. Above all, much progress has been made in barking the Cork trees, an operation which consists in stripping the rough bark off the trunks of the trees to the height of 5 or 6 feet from the ground. This virgin bark is without value, and only ten years after the trees have been robbed of it, is the inner bark available for commercial purposes, the trees giving a crop of Cork every ten years. To meet the expenses incurred in these operations there were available the sums accruing from the sale of the trees already felled, and of the bark of the 'Zen' for tanning. Little has been done towards working the less valuable forests to the south of that river. An experiment has been made in planting with trees a small tract of mountain land near Hammam-el-Enf, some ten miles to the east of the town of Tunis. The operation consists in digging holes at short distances, and in dropping in each a few seeds of the Pine tree. Several hundred acres have thus been planted with tolerable success, at an expense of £4 10s. an acre.

"The worst enemies of the forests are goats. Some French colonists have taken steps to exclude these animals from their estates, and the result has been that shrubs, which never attained the height of more than two or three feet, have in four or five years assumed the dimensions of trees. This is particularly apparent in the large domain of Enfida, where a *Thuja*, which covers much of that region, from a dwarf shrub has now, within the space of six years, attained a height of twenty to twenty-five feet. The French railway company, which owns the line running from Tunis to the Algerian frontier, has succeeded in planting a considerable number of the *Eucalyptus resinifera* (the Red Gum tree), and *Acacia cyanophylla*. It is estimated that 300,000 trees have been planted along the line of railway.

"The cost of planting an acre with the *Eucalyptus* amounts to £20, about 1,600 trees going to the acre of nursery ground. After planting out, it is probable that at the end of twenty years 600 trees will have survived, worth 8s. apiece.

"The bark of the *Acacia cyanophylla* is rich in tannin, and valuable for the tanner. In the whole of southern Tunis there exists but a single forest, formed of a species of *Acacia*. It is situated about twenty-five miles inland from Ifax, and covers an area five miles long by a little over a mile in width. This forest, which was formerly much more extensive, is protected from the northerly winds by high land, and the trees grow in clumps in depressions of alluvial soil. Though they only attain a height of ten feet, the trunks furnish planks eight or ten inches wide, of an exceedingly hard grain, and capable of taking a fine polish."

Answers to Correspondents.

"Why is it not the best forest policy to cut out the mature wood from a primeval forest and let the rest grow?"

A. J. K.

If the questioner had asked: Is it proper forest policy to utilize the timber for which there is a market and to provide at the same time for a new growth? he would have exactly stated the very end and aim of forestry, and we would have assented without qualification. But whether the best method to attain this end, especially the latter part, is presented in the prescription contained in the above question, must depend on a special diagnosis. The method of taking only what is called "the mature or ripe wood" (who knows what that is?) or, as it may be called, the "method of selection," is at least an attempt at forest management, and the beginning of order and system, and where, as with us, forestry is as yet undeveloped, this method is decidedly better for the future of the forest, than indiscriminate slashing and clearing. It is, however, not the best, and in many cases a bad method of forest management, unless practiced with great circumspection. Its advantages lie in the preservation of a protective forest cover, and in the continuance of a natural forest in an advanced stage of development, the value of which must increase with the necessarily decreasing supplies of mature timber. But this depends somewhat on what "the rest" is. We can conceive of a natural growth, in which "the rest" is composed largely of inferior or undesirable growth, when it would be better policy to cut out the inferior growth first, work for a reseeded from the old growth, and then remove the old timber gradually, to have resulting a desirable young growth. When "the rest" consists of well-grown shade-enduring timber, like the Spruce in the forests of

Maine, where, after the removal of the old timber, the remaining growth has sufficient vitality to be benefited by the increased light influence, this method may be even recommended, at least for some time to come.

But, looking further into the future, this policy will ultimately not prove the best, as it is bound, by and during the frequent removals of older growth, to damage the young growth, which at the same time gets but little chance for development under the continued shade of the older growth, and gradually the valuable forest "runs out."

It is, however, possible to conceive of this method of selection under given circumstances and when skilfully manipulated with regard to the needs of an aftergrowth as good forest policy, and on the mountain slopes, where the preservation of a forest cover rather than the production of the most valuable timber is the object, it is decidedly the best policy.

Recent Publications.

A Catalogue of Niagara Plants, by David F. Day.

To the Report of the Commissioners of the State Reservation at Niagara, recently presented to the Legislature of this State, Mr. David F. Day, of Buffalo, has joined a catalogue of the plants found growing spontaneously upon the Reservation and in its immediate vicinity. In a very interesting introduction to this carefully prepared work it appears that it is based upon observations made in the neighborhood of the Falls during a period of twenty years. Probably, therefore, the catalogue is nearly complete, although Mr. Day modestly states that he may have overlooked a few species of Grasses, Sedges and other difficult plants. In the prosecution of his task the author has consulted, as far as possible, the observations made in this neighborhood by other botanists. The references to the botany of Niagara Falls, especially by the earlier explorers, are few. It is possible that Peter Kalm, the pupil and correspondent of Linnæus, may have left some record of his observations made at Niagara in 1750, although no mention can be found of their publication, either in the Swedish original or in translations. If Kalm's journal still exists its publication would be a welcome addition to the literature of American botany. It is probable that he discovered the *Hypericum* and the *Lobelia* which bear his name near Table Rock. There is no evidence that either Michaux or his son ever visited Niagara, and it is certain that Pursh came no nearer to it than the site of Elmira. Nuttall, who botanized near the Falls before 1818, mentions but one plant found by him there—*Utricularia cornuta*. Torrey was probably familiar with this region, although in his "Flora of the State of New York," published in 1843, he mentions as peculiar to Niagara, but wholly upon other authority, only 15 out of the 1,511 plants which he describes. The labors of later botanists, however, have been more useful to Mr. Day in the preparation of his catalogue. The journals of Judge Clinton, prepared while he was engaged in studying the botany of Buffalo and its vicinity, proved of the greatest value, as did the "Flora Canadienne" of the Abbé Purvancher and Macoun's "Catalogue of Canadian Plants."

The Flora of Goat Island shows few plants that are uncommon in western New York. Still, the island is rich in the number of its species. Perhaps no tract of its size in that vicinity can exhibit so large a number. Its vernal beauty is attributable not merely to this variety of plants, but also to the great abundance in which they are produced. It is probable, moreover, that the island formerly contained other species which are now extinct, such as several Orchids and Lilies. The Harebell has disappeared within a comparatively short time, and the Grass-of-Parnassus is fast going—the result of reckless flower-picking. The same fate awaits the Blood-root, the Dutchman's Breeches, the Wake-Robin and other charming wild flowers, unless the Commissioners succeed in putting a stop to this wholesale spoliation. They should endeavor, too, to restore those plants which have been exterminated from the island—an undertaking neither difficult nor expensive.

The value of this catalogue is increased by the references it contains to many rare and interesting plants found near the Reservation, although not within its borders. Of the 908 species of plants named in the catalogue 757 are native and 151 are foreign.

The *Revue des Deux Mondes*—March 1st, 1888—contains an article on "The Composition of Forests"—by the distinguished palæontologist the Marquis of Saporta, which sets forth how the present constitution of the forests of various parts of Europe is explained by the changes of climate which have taken place in successive geologic periods, and is illustrated by the fossil record.

Flower Market.

NEW YORK, March 30th.

Trade has been fairly good this week to supply numerous Church orders for Holy Thursday and considerable elaborate funeral work. The long period of dark weather will interfere with Easter bloom to a certain extent. As is usual at this time, white flowers are being held back for use on Sunday. As far as possible florists are resolved not to alter prices for Easter. There is a gorgeous display in the floral shops of plants, but it will not be as large as that of last year. Prominent dealers make grand exhibitions of Orchids, arranged in banks, where choice varieties of Vandas, Epidendrums, Cattleyas, Oncidiums and Cypripediums are offered for sale by the plant or spray.

Selected Hybrid Roses have risen to \$1 each. A limited number of Her Majesty Rose are brought in, and bring \$1.50 each. Tea and Hybrid Tea Roses remain as quoted last week. Plants of *Lilium Harrisii* cost from \$1 to \$2, and single flowers from 35 to 50 cts. each, according to the location. Plants of Calla with one flower and bud bring \$1. Cut Callas cost 25 and 30 cts., White Ascension Lilies are 15 cts. each. A few Gladiolus (Shakespeare) are offered and sell from 50 to 75 cts. a spike. Lily-of-the-Valley of the best growth costs \$1 a dozen; inferior flowers bring 75 cts. a dozen. *Spiraea Japonica* costs \$1 a dozen spikes. Plants of the same of medium size cost \$1. French Marguerites are 35 cts. a dozen flowers, or \$3 for 100. Large plants well flecked with bloom sell for \$2.50. Boxes of cut flowers for gifts are more in demand than designs. Novelty for these boxes are Stephanotis and Orange Flowers. These sell for 50 cts. a spray. Spikes of *Vanda Suavis tricolor* sell for from \$3 to \$5. There are from six to eight flowers on them. An Azalea (Artevelde) six feet high brought \$10; a plant of Genesta seven feet high \$20. Hydrangeas are exquisitely tinted and sell for from \$2 to \$5 a plant. French Marguerite Flowers are of an unusually large size.

PHILADELPHIA, March 30th.

Owing to the approach of Easter, flowers are plentiful, Carnations amongst staple articles being the most scarce. Grace Wilder, a delicate pink, is still the favorite, and with more sunlight and heat is improving in quality. Buttercup, yellow, with red stripes, comes next in favor. Whites will be most in demand at Easter. Swayne and Lamborn are amongst the best new sorts. Hinzie's White is also good; it brings from 35 to 50 cts. per dozen. Tulips are frequently delivered at the stores growing in shallow boxes; they make a gorgeous display. Cottage Maid, rosy pink, shaded with white Duchess de Parma, bronze-red, edged with yellow, Kaiser's Kroon, similar in color, but lighter, and the red and yellow more clearly defined, are all favorites, as are also the yellows, Chrysolora and Yellow Prince. Whites and solid reds are in demand too. They sell at from 75 cts. to \$1.25 per dozen. Violets are not so good in quality as they were; some of the single ones are poor, and sell at from \$1 to \$1.50 per 100, according to the quality and variety. Single varieties, when good in quality, are favorites here. *Asparagus tenuissimus* will be more used for Easter decorations than formerly. This is brought about through the scarcity of Smilax; it sells at from 50 to 75 cts. per string. *A. plumosus* is not at all plentiful. It is preferred to *A. tenuissimus* when obtainable at the higher price. Roses—Magna Charta, Captain Christy, Madame Luizet, Baroness Rothschild, Mrs. John Laing and Jacqueminots, amongst Hybrid Remontants—are plentiful, and sell at from \$3 to \$8 per dozen, according to location, variety and quality. Puritans, with the advancing season, continue to improve. Catherine Mermets are not a good color. Bennetts are fine when fresh, but their disagreeable tendency to become blue with age renders them less valuable than they were early in the season, especially since Jacqueminots have become so abundant.

BOSTON, March 30th.

The flower stores are gorgeous with Easter plants and flowers. The use of plants in churches has become almost as general as the use of cut flowers. For this purpose are offered a variety of showy, flowering plants, among which the Harrisii and "Longiflorum" Lilies must be given first place. Fine pots of these bring from \$2.00 to \$5.00 each, according to the number of blooms. Quite as showy as the Lilies, and more durable, are the Hydrangeas. The variety most generally seen is that known as *H. Otaksa*. Plants are offered in all sizes, from \$1.50 to \$5.00 each. Spiræas and Cinerarias are also to be had in profusion, and are worth from \$1.00 to \$1.50 per pot. Cut Lilies and Callas bring \$6.00 per dozen. The old-fashioned White Lilies bring from \$2.00 to \$3.00 per dozen flowers on stalks. Cool weather has been favorable for the Rose crop. The quality of Roses to be had for Easter in this market has never been better. Magnificent Hybrids are offered at \$12.00 per dozen. The best Mermets, La France and Jacqueminots bring from \$4.00 to \$6.00 per dozen. Lilies-of-the-Valley, Tulips and Daffodils continue at \$1.00 per dozen. Carnations have advanced in price, and good, long-stemmed fancy varieties bring \$1.00 per dozen readily. Immense quantities of Violets and Pansies are always used for Easter; \$1.50 per hundred is the price quoted. Smilax is very scarce at 50 cts. per yard. The new climbing Asparagus, which is more beautiful and lasts longer than Smilax, is largely used as a substitute.

Arbor Day.

THIS festival, which originated about a dozen years ago in Nebraska, seems already to have won an established place among American holidays, and some thirty of the States will observe the custom this spring. The very existence of such a celebration is proof of an awakened interest in tree planting; and that it has been made to a certain degree a public-school holiday is encouraging, because this indicates the direction in which such exercises may be made to have a genuine value.

Roadside tree planting is not forestry, nor can it in any way serve the purpose of forest planting or of forest protection. It may be worth while, too, to suggest to some enthusiasts that planting rows of trees by every roadside is not commendable, and that planting the wrong kind of trees in any position, or planting suitable kinds badly, invariably means disappointment and loss. The failure of many plantations along the railroads of some western States, owing to improper selection and worse care, has wrought injury far beyond the mere loss to the companies. It has discouraged others and engendered a belief that all attempts in this direction are hopeless. Nor will the attractive exercises of Arbor Day serve any effective purpose unless the trees are intelligently selected and planted. Distorted and sickly growth or early death of the trees will follow to the disheartenment of all who planted them so joyously and hopefully.

As a people, Americans are not over sentimental. But this sudden awakening to the peril that threatens our forests, may lead to the error of esteeming it something like a crime to lift up an axe against any tree. Mr. Gladstone has said that the greatest obstacle to a sound forest policy in Great Britain was the superstition that invested trees with a certain sacredness, so that felling one was looked upon as sacrilege. We occasionally observe the same feeling manifested here by worthy people who, in their new-born zeal, are led to speak of all lumbermen as enemies of the human race. Of course there can be no system of forestry without tree-cutting, and the protest, to

have any value, should be made against wasteful cutting or the stripping of mountains, where the trees serve a higher purpose as a protection to the water courses than they can when made into lumber. It often happens, too, that to secure the highest landscape beauty, trees that are improperly placed need to be removed, and every one who has had charge of public parks has been rebuked for vandalism when it was necessary to sacrifice a tree or a group of trees.

Now, the antidote to any extravagance of this sort is a knowledge of trees and their uses; and the hopeful feature in this Arbor Day celebration is that which makes it essentially a school holiday and connects it with the educational system of the State. It will serve no worthy purpose when the Governor of a great State, as a part of the solemnities, plants White Pines to struggle with the smoke and dust of a city square. But if it can be made an object lesson to the young, as the crowning ceremony of a course of instruction on trees and their needs and uses, it may become an educating influence of serious value. Beyond question, the children of our public schools are entitled to some elementary teaching in regard to the abundant tree growth all about them. It is a scandal that they should grow up in ignorance of the very names of the trees they see every day, and that they should know nothing of their uses or of the laws that control their development. Ability to give instruction in this direction should be required as part of the equipment of every teacher. And if, in addition to the instruction received, the children are led to plant trees with some holiday ceremony, they will be likely to watch their growth with a personal interest and note what helps or hinders it. The beautiful custom of planting memorial trees is one against which even the man who delights to style himself "practical," can offer no objection; and if a child is induced to give closer observation to a tree because it is called by his name, the gain is substantial; for the cultivation of habits of observation and comparison is of itself an education.

Arbor Day will exert a beneficent influence if it does anything to hasten the time when even the children can give an intelligent reason for choosing a particular tree for a given place or purpose, and when they know how to plant it properly, and to give it the care it needs thereafter.

A Dangerous Measure.

A BILL authorizing the Forest Commissioners of this State to lease portions of the forest preserve, not exceeding five acres in extent, and for periods not exceeding five years in length, has already passed the Assembly and awaits the action of the Senate. This bill emanates from the Commissioners, whose duty it is to protect and preserve the State forests, and they recommend and urge its passage. It is a measure fraught with danger to the Adirondack forests, and it ought to be defeated.

The history of this bill, and the reasons which have induced the Commissioners to recommend this remarkable policy, are, as we understand them, briefly these: A large number of persons have, at different times, entered upon the State domain, within what is now the forest preserve, and, without legal authority, have built for themselves summer homes on the land thus occupied. Many of the most beautiful islands in Lake George, and some of the most desirable sites on the Adirondack lakes, are now held in this way by squatters. Among them are men of wealth, and men of social and political influence. These facts make the position of the Commissioners a delicate and difficult one. If they allow the squatters to remain, they lay themselves open to serious charges of malfeasance in the execution of a public trust; if they take steps to have them removed from the State lands they create personal hostility against themselves. They hope, however, by obtaining authority to lease portions of the forest, to legalize this unlawful occupation of State lands, and at the same time

to put themselves in a position to be able to supply eligible building lots for summer homes at low rates.

This should not be allowed. The bill is too general and sweeping in its provisions. It gives too much power to the Commission, and throws too much temptation in their path. The policy of forest management, which its passage would inaugurate, is, we are convinced, a dangerous one. The only reason that justifies the State of New York in holding lands in the Adirondack region, is that the forests which grow upon them may be properly protected and preserved. These forests have an important and controlling influence upon the prosperity of the whole State. If they are to be parceled off into five-acre building lots it will be impossible to carry out any scheme of forest management. Settlers, even when they are rich, and possess social and political influence, are a constant menace to the forest. They increase the danger of fire; they stamp out or clear up the undergrowth, even when they do not destroy or injure the trees, and they are, when they become numerous, a powerful incentive to railroad building.

If a wealthy citizen of this town should ask the privilege of building a summer-home for himself in the Central Park, the proposition would be considered monstrous. The proposition to use the Adirondack forest-park in a similar manner only differs in degree; it is equally monstrous, and might become far more dangerous. There are now comparatively few settlers in the Adirondack forests, but the number is increasing every year, and if the authority to lease land is given to the Commissioners, sooner or later every lake will be lined with settlements and every available site in the forest will have a cottage on it. All the wild and rural charm of the woods will be destroyed, their usefulness as a great popular sanitarium will come to an end, and it will be merely a question of time, when the State forests must be destroyed, or lose their essential value.

There is still territory enough in the Adirondack woods, outside of the State preserve, for a large population, and no hardship will be inflicted in shutting up the public lands from settlement, except in the case of persons who have made expensive improvements on land to which they never had a title, and which now they should be compelled to vacate.

The Commission has doubtless been led to advocate this measure through ignorance of the dangers which its adoption would entail in the end upon the forests. It is not to be believed that they have done so in full knowledge of what a forest really is, and of the requirements of even the crudest system of forest preservation. They have now, however, an opportunity to show their zeal and public spirit. The Adirondack forests are about to be cut up and seriously injured by the building of numerous railroads. The forests, or at least those portions of them which belong to the State, can still be saved from this new danger by a vigorous effort to secure restraining legislation. It is the duty of the Commission to make this effort; its members will find themselves supported in it by public applause and the assistance of the people of this State.

Street Trees.

IN no branch of rural economy, perhaps, are Americans so far behind the people of almost every country of Europe, as in the selection, planting and care of street and road-side trees; and this is particularly true in the case of the plantations made in most of our larger cities and their suburbs.

Two mistakes are almost invariably made in undertakings of this character in the United States; the work is done too cheaply, and the trees are badly selected with reference to future effect. Saplings dug from the woods with mutilated roots and branches, are planted in shallow soil, and are then left to struggle unaided against the enemies which beset urban and suburban trees—

drought and dust and starvation, gnawing horses and ravaging insects. In the case, for example, of a great public improvement now in progress near one of the principal cities of the United States—an improvement which is dependent entirely upon a growth of stately shade-trees for its value and to which its promoters are fond of alluding as “an American *Champs Elysées*”—it has been seriously proposed to plant trees dragged from a neighboring swamp in strips of earth four feet wide and only one foot deep, resting on a bed of porous gravel. It is needless to say that trees planted in this way could never do more than drag out a brief and miserable existence.

There is no poorer economy than trying to plant street trees cheaply. Unless the work can be done well it had better not be done at all. The ground should be thoroughly prepared, and well-selected nursery-grown trees, carefully pruned for the purpose, should alone be used. The American habit of taking saplings from the woods, cutting off all their branches and half their stem, and then using them as street-trees, cannot be too strongly condemned. The result of such treatment is this. A fork is formed by two or more horizontal branches pushing up from the top of the cut stem. Water gathers and stands in this fork, and gradually carries decay down into the trunk of the tree, destroying it long before it reaches maturity.

Street trees not only should be carefully selected and thoroughly planted, but if anything like a satisfactory result is expected, should be protected from gnawing animals, and judiciously pruned as often as pruning is necessary to keep them in proper shape. The mistake of too close planting is almost invariably made in this country, and trees planted thickly for immediate effect are rarely thinned in time to prevent their injury by overcrowding.

In the matter of selection we make as many mistakes, and almost as serious ones, as in our methods of planting. It is a well established rule, based upon common sense, that trees of one variety only should be planted on one continuous street or avenue. The reason is obvious. If trees of different varieties are used, that uniformity essential in urban planting to the production of harmony of effect will be lost. Trees of different varieties grow differently. Some grow more rapidly than others; some come into leaf and some lose their foliage earlier than others; some, as they approach maturity, assume a stately, and others a graceful aspect; and variety which may make a country road-side beautiful, is entirely out of place in connection with the formal lines of city buildings. This rule is rarely observed in the United States. Trees of one variety are rarely planted here in continuous lines. The pendulous American Elm alternates with the rigid-branched Sugar Maple, or a heavy Horse-Chestnut is seen between two sprawling Silver Maples.

Such combinations of trees are incongruous when planted and age only makes them worse. Roads here and there in New England planted exclusively with the Sugar Maple or with the Elm, or in some of the far Southern States with the Water Oak, serve to show how much more beautiful and effective a street plantation can be made by using one variety of tree, than by any possible combination of different varieties. Or, to cross the Atlantic for examples, the continuous avenues of Planes, of Lindens and of Horse-Chestnuts in Northern Europe, of Sophoras in Italy and of Ailanthus in Paris, clearly teach the same lesson.

Now is the time when plant-orders from all quarters and from all sorts of people are pouring in upon nurserymen. Many of these lists display an ignorance of the first principles of good planting which distresses the expert nurseryman, and the lack of assurance that the plants of even the better lists will be arranged to advantage often troubles his mind still more. For he knows that trees and shrubs, however well chosen, may yet be so unadvisedly planted as to produce no harmonious effect; that they may easily be placed so as never to really satisfy the hopes of their planter,

and never be any credit to their grower, the nurseryman. The owner of a suburban lot or of a country-seat reads the descriptions in a catalogue and writes an order, perhaps for several hundred dollars' worth of plants. Some day the stock arrives, and the owner and his gardener, or perhaps a "landscape gardener" from the nursery, proceed forthwith to planting. The result may be seen in the suburbs of every city and in many country estates. Everywhere are nursery novelties indiscriminately scattered among native wood and shrubbery, or dotted as single specimens all over the lawns. Even as specimens the plants are seldom arranged with good effect. The whole method of procedure is wrong. The fault is not the gardener's, for the most accomplished artist could render small service, if he were called on only after the plants had been delivered on the ground.

The designing of plantations, large or small, calls for the best skill of the real landscape gardener. They should be made to harmonize with the existing natural features of the ground; they should not destroy, but should, if possible, emphasize its natural character. Even for suburban lots, their proper planning requires much knowledge of the nature of plants, much imagination, and much careful preliminary study upon paper. It is safe to say that the nurseryman who secures many orders from professional landscape gardeners, or who persuades his customers to make or get planting-plans in advance, will possess a more comfortable mind and conscience, and will find himself far better advertised by his plants, than his rivals.

Senator Vest's bill providing, among other things, for the extension of the boundaries of Yellowstone Park towards the south and east, is one which should be promptly passed. The enlargement will include the western slope of the Absaroka Range, with the timber land at the sources of the mountain streams flowing into the park, as well as those which flow eastward into the Big Horn. This proposed addition to the park is so rugged in surface that it can never be subdued to agricultural use, and from its geological formation it is safe to pronounce it utterly barren of mineral wealth. But as a part of this great natural reservoir where waters are stored to find their way to both oceans, the forest here is of incalculable value. Not only will these coniferous woods restrain the melting snows of winter, but here, unlike most of the Rocky Mountain region, are summer rains to be husbanded as well. Many of the streams which receive part of their supply from this region can be used for purposes of irrigation, and upon this will depend the success or failure of agriculture for thousands of square miles. This is only one of many areas along the Rocky Mountains which should be set apart as forest-land forever, but from its connection with the Park it is a promising place to begin. There should be little difficulty in passing Senator Vest's bill.

It does not seem as though taste in the arrangement of flowers was at a very high level in this country, when we read the following paragraph, descriptive of a construction that was exhibited in a Western city not long ago: "Upon an easel of Cat-tails a velvet plaque rested. The latter was decorated with a cluster of Roses, and at one side, resting upon a branch of Holly, was a little owl made of Violets and natural enough looking to fly away. Beneath was a nest full of eggs." But reading it quoted with approval under the heading, "Another Pretty Thing," in a late number of a prominent English horticultural journal, we are somewhat consoled by the thought that if our taste is bad, it is no worse than that of the rest of the world.

It is proposed by French horticulturalists to erect a monument over the grave of Lacharme, the famous cultivator of Roses. The Viennese *Illustrierte Garten Zeitung* suggests that lovers of Roses in other countries should contribute towards the monument, and names M. Bernaix, 63 Cours Lafayette, at Villeurbanne-Lyon, in France, as the person to whom remittances may be made.

Landscape Gardening.—VII.

IF, as I have said, we look at any American town where homes of the better class are isolated in their own grounds, we must confess that they do not prove us as far advanced in the art of gardening as we are in certain other arts. Few villa-lots in any neighborhood show that the first requisite of a good effect has been considered—composition. Little regard is usually paid to the harmonious arrangement of contrasting forms, and still less, I may now add, to the harmonious arrangement of contrasting colors.

I do not propose to discuss the intrinsic excellence of that popular kind of gardening which is known as "bedding out," as "ribbon" or "pattern gardening." There are many who would almost invariably prefer to it some more natural disposition of bright-flowered or bright-leaved plants—something more like nature's own floral arrangements or like those of our grandmothers' days. But, given the fact that solid, bright-hued pattern beds may be intrinsically beautiful, how often do we see them used in a way which suggests the desire to make them part and parcel of a beautiful general scheme, and how often is that nice feeling for color which we are so fond of exercising inside our homes displayed in choosing and assorting the plants which compose them? The beds we most often see are ugly in shape, garish in their contrasts of tint, and disposed without due regard to anything around them. A man who would not for worlds hang a chromo on his carefully tinted parlor wall, contentedly puts chromos in Coleus and Geranium in the middle of a lawn the strong green tone of which throws their gaudiness into high relief.

If, now, we look at our larger country-seats and parks we find more palpable evidence of good taste. We have some admirable landscape gardeners in America, and, naturally, they are more often asked to manage large problems than small ones. But as yet they are not asked nearly often enough; and even when asked their counsels are not always respected. They may be allowed to lay out the grounds as they wish, but when once their backs are turned, how quick is the owner to retouch—and spoil—their work! How seldom does he ask himself what it was that his landscape gardener really wanted to do—what was the general effect he wanted to produce,—and then address himself to developing and preserving it! How seldom do we see any place, great or small, of which we can say, There is everything here that the eye desires—there is nothing that it could wish away! How surprised would almost any proprietor be, did we venture to criticise the view from his window upon the same principles that we should apply to a painting on his walls; and yet, unless it will stand such criticism, it is not what he has wished to make it.

Of course, only an experienced and capable artist can arrange any extensive gardening scheme with success. And even the smallest scheme is likely to be more successfully planned and more rapidly perfected under an artist's eye. Yet even if his help is unattainable there is no reason why we should resignedly fall back upon haphazard ways of working. Any man can try to work in an artistic spirit, even if he cannot rival an artist's skill in execution. That is to say, no result made up of various elements—even if those elements be the very fewest in number—can be good which is not good as a whole; to make it good as a whole we must begin by having a clear idea of what sort of a whole we want; and to begin with such an idea is to work in an artistic spirit, no matter how well or poorly we succeed in giving it beautiful expression. The scheme is the main point—the scheme and the will to stick to it and not be tempted by the beauty of individual things into frittering away or confusing its effect.

Is it needful to say that working in this spirit we should not only work to better eventual effect, but with greater pleasure at the moment? To have some appropriate and charming little picture in our minds which we want to realize; to dispose our ground, and to choose and place our plants, with the requirements of this picture before us—

this is to get the highest degree of pleasure from our planting. Nor can it be objected that when the picture is once arranged, then our work and pleasure are over, unless it can be perpetually tampered with and disarranged. To the artist the mutability of nature is often a heavy cross, since he knows that when his result is considered finished he must leave it to others who will permit it (even if they do not aid it) to transform itself into something very different. But to the proprietor or gardener who is trying on a modest scale to emulate the artist, this very mutability insures the permanence of his pleasure. Day by day and year by year he can watch the development of his picture, guard against Nature's disfiguring retouches, welcome her happy accidents, and carefully correct and retouch his result himself while preserving its general integrity. And this work will surely be pleasant, for to the scientific satisfaction of the cultivator will be added that purest of all delights—the consciousness of being a creator in the field of art.

M. G. van Rensselaer.

Which is the Better Way?

ONE difference between landscape painting and landscape gardening is that the trees and shrubs in the picture of the painter do not grow, while those in the gardener's picture do grow. Hence the former is free to show his group fully grown at once, while the latter must wait for years until his little specimens attain the desired size.

Two methods of planting are practiced. One attempts to produce present effect; the other aims at ultimate results.

Planting material is usually small. This is especially the case where novelties are used. Hence a design of planting, no matter how carefully studied for future effect, may give meagre results at first—the grounds will appear not fully furnished, and the impatience of the owner will compel the landscape gardener to plant greater quantities than one educated to foresee future effects would deem advisable.

On the other hand, if the design is made to produce immediate results, the growth of the planting will in time cause a surfeit, and finally the grounds will appear to be as much overplanted as they would at first seem to be unfinished on the other plan, and with this difference, the overplanted grounds will not improve, but the surfeit will increase. Individual specimens will encroach upon and destroy each other. Here the "survival of the fittest"—that is, the fittest for beauty and interest—will not always occur. The more delicate, and, oftentimes, the more beautiful, will be crowded out by the coarser growing kinds. As a reply to this objection, how many times have I heard it said, "Oh, well, we will 'thin out' as the specimens grow." But the trouble is, the owners of overplanted ground do not "thin out," but everything is left to grow together "until the harvest," and that harvest generally is a rooting out of all and a more judicious planting made to take the place of the old. Sometimes it happens that the harvest is deferred until the harvester appears in the person of a new owner.

I have in mind a case of overplanting which I was called upon to remedy some ten or twelve years ago. The former owner had died, and the property came into the hands of a new proprietor, who, soon after the purchase, sent for help. He said that he felt there was something the matter with the grounds, but he did not know exactly what. I suggested suffocation. "That's it," he replied; "see if you can get rid of it." And thereupon some four hundred trees and shrubs came out at once. In one or two instances it was absolutely necessary to remove more than would have been advisable had more judicious methods of planting prevailed at first. Masses of evergreens entirely filled up spaces where glades and vistas ought to have appeared. These would have been secured if two or three trees only had been originally planted, and even now the removal of a part of these masses would leave the needed opening; but the trees were so thickly grown together, that taking out a part would have exposed dead branches all up the sides of the trees left standing, and therefore the removal of every one was necessary.

From what has been said it appears that both methods of planting have their faults. That by which present effects are secured eventually produces a surfeit, which will not improve as time goes on. The design made to secure future results, at first gives an appearance of bareness, which gradually disappears as the design comes to full development.

In my reference to overplanted grounds, I have stated facts as they ordinarily occur. There are exceptions. Grounds can be and are planted so as to give pleasing results at first, and then are so carefully watched, and so promptly relieved of any undue crowding, that all continues satisfactory. Nevertheless, a long experience has convinced me that with a carefully studied design the most satisfactory results will follow when only those trees and shrubs are used which are intended to remain. The reason is obvious. In the first case the intention of the design becomes indefinite and wavering, as individual members of the overcrowded planting are removed, one after another, to make room for those which are to remain; in the second case, the result is definite, because the intention of the design continues the same. There is no change or fluctuation of purpose. The trees and shrubs when planted were given room for full development, and so to take upon themselves all the beauty and gracefulness of form with which nature has endowed them.

There is one way of securing both present and future effects, and that is the planting of large trees; but this is costly, somewhat doubtful in its results, and it can be of but limited use.

B. S. Olmstead.

[There are cultural advantages in planting trees and shrubs so closely that they will protect each other when small, and if the plants that are to remain were designated in the original plan and those used for supplementary purposes could be removed at the proper time, close planting would be the best practice. But few men have the strength and persistence of purpose to root out thrifty trees and shrubs as they begin to crowd, especially those which they have planted themselves. Besides this, frequent changes of owners help to defeat the best intentions in this matter. Therefore it is safer, as a rule, to plant only such trees and shrubs as are meant to have a permanent place in a design. It should be added that "novelties" should never be used to produce effects which require time for their development. Who knows how strange plants will thrive in a soil and climate to which they are not accustomed?—Ed.]

Cemeteries.

A CEMETERY is a space set apart from all other uses for the particular purpose of burying the dead and of erecting memorials to them. Its purpose, being so distinctive, should not be confused with that of any sort of public pleasure-ground.

This may seem too obvious to need pointing out, but the fact appears to be that almost every important cemetery becomes noted in a way which shows clearly that its real purpose has become confused with that of displaying what can be accomplished by certain decorative arts. Such a display is out of place and in bad taste. Obviously the rule should be that nothing which is decorative, rare, curious, historical or amusing should be allowed in a cemetery for its own sake, but only as it may aid the true purposes of a burial-ground. Too often, the aim appears to be to afford gratification to those who come to the cemetery in the same frame of mind in which they might be expected to go to a fine public garden; that is, on the alert to admire "Nature's bright productions," "triumphs of horticultural art," and things "rare and curious." They try to ignore the graves as unfortunate and inharmonious objects, but gaze with pride, if they are natives, or with envy if they are from another town, at the largest and most costly monuments, just as they would at a new court-house or triumphal arch. They are attracted as by a show. The cast-iron fences and most of the other

usual accessories, are sufficiently well adapted to aid in the pleasurable impression which the big, showy monuments and the ribbon-gardening make upon this class of visitors.

The custom of making a display of pretty flower-beds is questionable. A cemetery should be built, planned and maintained with sole regard to its prime purpose, and every respect should be shown for the feelings and sentiments of mourners and those who visit the place in a serious and contemplative frame of mind. Not that there should be a prevailing aspect of gloom and sadness, or anything approaching desolation and dreariness; but certainly any appearance of gaiety and festivity, and all bright, lively, ephemeral decoration such as might be appropriate to certain kinds of pleasure-gardens, should be carefully avoided.

The best that planting can do for a cemetery is to give an appearance of unity to a necessarily more or less heterogeneous collection of individual monuments; to give as much sense of seclusion to all parts of the grounds as possible; to isolate each monument from its neighbors; and to form a background and frame to each important monument. A certain kind of decorative planting is admissible, on the same principle that picture frames may be decorated. That is, it should be in keeping with and subordinate to the greater work of art which calls it into existence, but it should be used very moderately and with careful discrimination, else it had far better be omitted. Simplicity is the safest rule to follow in most instances.

J. C. Olmsted.

A Disease of Certain Japanese Shrubs.

IN regard to Professor Gibbs' very interesting communication, p. 40, I would say that I have noted this disease for a good many years. We call it the Japanese "die-back." The cause thereof I know not, but I have observed that it is aggravated when the plants are grown under unfavorable conditions. As a rule, Japanese trees and shrubs dislike drought in summer or winter, hot sunshine at any time, and exposure to searing winds in winter. I have found that Japanese Maples grown in good loamy, moist ground, well sheltered, and faintly shaded in summer, are very little affected by the "die-back," but when grown in exposed situations and dryish sandy land, they are very subject to it.

Cercis Japonica with us has the tips of its shoots killed back a little every winter, but otherwise it behaves very well. *Exochorda grandiflora* does not seem affected. *Staphylea Colchica* suffers in this way. *Viburnum plicatum* does not show this disease in our garden, but I know of it in New Jersey, where it is not only affected by this disease, but the ends of the shoots get killed back nearly every year as if it were not hardy enough. *Cercidiphyllum* is hardy and healthy with us; so, too, is *Elæagnus longipes*. *Ampelopsis tricuspidata* gets killed back a good deal in winter, but seems to enjoy immunity from the summer "die-back."

But we have other than Japanese shrubs that are affected with summer "die-back." Take, for instance, our native *Hydrangea quercifolia*; it is as bad, or worse, in this respect, than a Japanese Maple. And what can be worse in this way than *Rhus Cotinus*? Even of old and apparently most healthy specimens, half the bush will sometimes die back to the ground in summer, and unaccountably. Deciduous Azaleas likewise die back a deal in summer, but in their case especially I am certain the disease is greatly aggravated by unfavorable conditions of cultivation.

Wm. Falconer.

Fruit Growing in Florida.

TAKING up the subject of fruit culture in Florida at the point marked by the "semi-centennial freeze" of 1886, it may be said that the Orange, Lemon and other Citrus fruits have held their own, and that the crop of fruit next winter is likely to be four times as large as that which was nipped by the memorable frost.

Before the frost some little interest had been aroused in certain other fruits that had recently been introduced, and during the following year their merits were discussed with eager interest, for public confidence in the Orange had, in fact, been seriously shaken, and the importance of diversification was generally conceded.

The most noted of these new fruits were those odd Chinese Peaches, the Honey and Peen-to, the former with a beak-like

point, and the latter drawn in at both ends like a certain style of pin-cushion. The Le Conte and Keiffer Pears were also much talked of, and likewise the Japan Persimmon. On these the Florida nurserymen bestowed much attention in 1886, and still more in the following year, the demand for such stock increasing enormously. There are nearly 100 nurseries named and advertised in Florida, yet the population of the State, including negroes, is only about 400,000. Large orders for young Orange trees were received from California last winter, and tens of thousands were shipped to that State.

In 1886 one of the Japan Plums, which came from California nurseries under the name of Kelsey's Plum, was fruited in Florida from a bud of the previous year. It proved to be remarkably vigorous and precocious, bearing fruit of large size (over two inches in diameter), of fine flavor, with small pits, not subject to curculio—in short, a marvelously fine Plum, in all respects. During the same year some seedlings—perhaps hybrids—of the Chinese Peaches were brought to notice, and nurserymen have made a specialty of them. They are superior to the originals, and the tendency to variation indicates that, by selection, still better varieties may be obtained in the future.

Of the Pears mentioned, the Le Conte has grown steadily in favor. In the country around Tallahassee it was a source of considerable revenue last year, and plans are on foot for establishing an exchange for handling this year's crop. As to the Japan Persimmon, the only question is in regard to its qualities as a marketable fruit. It is hardy, healthy, and precocious in bearing, but, like the Loquat, its status is not fully determined. Both of these trees, as to foliage and fruit, are very ornamental, and are great acquisitions to the orchard, if only for home use. The same may be said of the Guava, which is scarcely less valuable to the people of the southern half of Florida than is the apple in more northern States.

The Grape is another fruit that has acquired prominence since the freeze of 1886. European grape-growers have established extensive vineyards in certain localities and have found some varieties to do remarkably well. Professor E. Dubois makes a specialty of wine-grapes. He is enthusiastic in praise of the Cynthiana and Norton's Virginia, two seedlings of *Vitis aestivalis*.

The Fig, Pomegranate, Mulberry and Olive have long been cultivated in Florida, and deserve more attention than they receive. The Fig grows almost spontaneously. The variety so extensively imported succeeds finely, and, with proper appliances for drying, it ought to be grown profitably for market. In the northern counties considerable attention has been bestowed on the Pecan and the English Walnut, and many plantations of them are growing. The Almonds and foreign Chestnuts may also be grown for home use.

To summarize, the present aspect of fruit-culture in Florida may be stated as follows: On the southern coast Pineapples are grown for market in large quantity, and large plantations of Cocoanuts have been started. Many other West Indian fruits are grown there for home use. Throughout the southern half of the peninsula the Pineapple and Banana fruit well, and the latter is grown for ornament throughout the State. The Mango, Avocado Pear, Sugar Apple, Sapodilla, and some other sub-tropical fruits, succeed well as far north as Tampa Bay, and Guavas nearly to the northern border, but a cold wave like that of 1886 will cut them down. All the fruits previously mentioned do well, except in the southernmost counties.

The fruits shipped out of the State rate in importance about as follows: Oranges, Pineapples, Strawberries, Pears, Peaches, Grapes and Persimmons. The Apricot, Quince and Apple are occasionally met with. The latter promises to succeed best grafted on the Pear. Of Plums, numerous varieties are in cultivation, the Wild Goose and Marianna being the best native varieties, and Kelsey's the best of the Japanese, with numerous others yet to be introduced. Of Peaches, the Peen-to and its seedlings succeed well in sandy lands, and some varieties of the Persian strain where there is clay sub soil.

Taking a brief retrospect, it is evident that horticulture in Florida has made greater advances within the last two years than during any four years in her previous history. Hundreds of thousands of deciduous fruit-trees and vines have been planted. New varieties have been tested. More attention has been given to the science of horticulture. A reform in the system of selling and shipping Oranges and other fruits is in progress. Improved transportation and appliances for refrigeration are being provided. Fruit-growing is steadily increasing in importance, and in most portions of the State it will long continue to be the favorite industry.

New or Little Known Plants.

Yucca filifera.

THIS, the "*Palma*" of the Mexicans of Nuevo Leon, and the largest of the known species of *Yucca*, is certainly one of the most remarkable and interesting trees of North America. It was first discovered about 1840, near Saltillo in north-eastern Mexico, by Dr. J. Gregg, author of the well known "Commerce of the Prairies." It was next seen in December, 1852, between Parras and Saltillo, by Dr. George Thurber and a party of the United States Boundary Commission, and is referred to, but without characters or description, in Dr. Torrey's "Botany of the Boundary." A figure of the tree, however, appeared in Mr. Bartlett's "Personal Narratives" of the Boundary Surveys, vol. ii., p. 491.

by whom plants were raised and distributed. One of these flowered in 1876, in the garden of the Baron Prailly, near Hyères, and was figured and described by Chabaud in the *Revue Horticole*, under the not very fortunate name of *Yucca filifera**, by which this tree must now be known.

Yucca filifera is a wide-branching tree often 50 feet in height. The short trunk, 15-20 feet high in fully grown specimens, and not rarely five feet in diameter above the somewhat swollen base, is covered with dark brown scaly bark. The leaves, persistent upon the stout branches for many years, are thin, smooth, narrowly oblanceolate, 18-20 inches long, with fibrous edges, the threads white, or sometimes reddish-brown. The pendulous panicles appear in April and May; they are 4-6 feet long and 18-20 inches wide. The flowers are small, 2-3 inches wide, the ovate, or lance-ovate, narrow segments rarely exceed-

Fig. 13.—*Yucca filifera*

This figure very well shows its habit except that the great panicles of flowers are represented upright on the summit of the branches as in other species of *Yucca*, an error due, no doubt, to the fact that the trees, being at that season of the year out of flower, the artist was obliged to draw upon his imagination so far as the inflorescence was concerned. This mistake led Dr. Engelmann, with only the very insufficient material brought home by Gregg and Thurber at his command, and after him Mr. Baker in England, to consider the plant a southern variety of *Y. baccata*, from which, however, it differs in its much thinner and smoother leaves, smaller flowers, shorter and less fleshy fruit, and pendulous inflorescence. Some time previous to 1860, the collector Roehl rediscovered the tree, and sent seeds to the nurseries of Huber & Co., of Hyères, in France,

ing an inch in length. The baccate pendulous fruit, often constricted on the side towards the stem, is 2-2½ inches long, with seed often exceeding a line in thickness.

Yucca filifera is a conspicuous object on the arid plains which rise from the Rio Grande to the foothills of the Sierra Madre. The great panicles of white flowers can be seen for miles in the clear atmosphere of that region, and look like gleaming waterfalls pouring out from the ends of the branches. It first appears about 50 miles south of the Rio Grande, where, with the beautiful white-flowered *Cordia Boissieri* in the depression of the plain, it forms an open picturesque forest which extends almost to the valley

Fig. 14.—*Yucca filifera*.

of Monterey. The *Palma* is common in the plains between Saltillo and Parras; it was seen by Dr. Parry as far south as San Louis Potosi, and it will be found, no doubt, to extend widely over the high dry plains of north-eastern Mexico.

This tree is often cultivated by the Mexicans at both Monterey and Saltillo, the young plants being used to form high impenetrable hedges about houses and stock-yards; and flowering plants, from Roezl's introduction, are not rare in the gardens of Southern France, Algeria and northern Italy. It is hardy, according to Naudin*, wherever the Orange will thrive. Our illustrations (fig. 13, p. 78, fig. 14, p. 79) are from photographs taken near Monterey by Mr. J. M. Codman.

Chionophila Jamesii.*

IN 1821 Dr. Edwin James accompanied as naturalist the government party which, under Capt. Long, ascended the South Platte, skirted the eastern base of the Rocky Mountains as far southward as Colorado Springs, and thence returned east by way of the Arkansas. From Colorado Springs Dr. James made the first ascent of what is now known as Pike's Peak, and there gathered the first collection that had ever been made of the alpine plants of western America. Among them was a single specimen of the plant

*C. JAMESII, Benth. in DC. Prodr. x, 351. A dwarf alpine perennial, glabrous or nearly so, with thickish entire oblong-lanceolate radical leaves; stems scape-like, bearing one or two pairs of narrowly linear leaves and a close secund imbricately bracted spike; calyx broadly funnelform, with five short blunt teeth; corolla cream-color, tubular, half an inch long, with short bilabiate limb and bearded in the throat; sterile filament glabrous.

which is here figured. This, with others, was referred to Dr. Torrey for determination, but unfortunately it became mixed with specimens of *Pentstemon Jamesii* and so was overlooked, and eventually found its way to the herbarium at Kew. Here, twenty-five years later, it was detected by Mr. Bentham while he was preparing the *Scrophulariaceæ* for DeCandolle's Prodrômus, its peculiarities were recognized, and it was described as a new genus. Fifteen years later still, in 1861, Dr. C. C. Parry ascended the cluster of now well-known peaks which were named by him Torrey, Gray and Engelmann, and upon the summit of Gray's Peak he rediscovered James's plant. Since that time it has been found in the same region by several collectors, but it yet remains the sole representative of the genus.

As shown by the figure, the leaves are mostly in a basal cluster, with one or two pairs of linear ones upon the low scape-like stems. The cream-colored flowers are in one-sided bracted spikes, the two-lipped corollas bearded in the throat and not greatly exceeding the calyx. The genus is closely related to *Pentstemon*, from which it is distinguished chiefly by the tubular and short-toothed calyx and by the spicate arrangement of the flowers. This inhabitant of our highest snow-clad peaks cannot be said to be remarkable for its beauty, but as a rarity and as the only one of its kind it deserves a place in every collection of Alpine plants.

Pruning Shrubs.

TO the repeated inquiry as to the best time and method of pruning deciduous shrubs, it may be answered that no single rule can be laid down that will apply to all cases. Shrubs, like trees, are pruned for different purposes, and what is good practice in one case may be ruinous in another. A tree for the lawn requires different treatment from a street tree, and the rule for pruning an apple tree to induce an abundant yield of the best fruit would not apply to another tree where timber or fuel was desired. In the same way the pruning of a shrub may be good or bad according to the object chiefly desired. What is the best practice when the production of flowers is the main consideration may be far from good practice when the symmetry or grace of the shrub itself is the leading purpose.

There is little doubt as to what is the worst method of pruning, and that is, shearing off the shrubs of a border, at a uniform height, as squarely as a hedge is trimmed, and cutting back single specimens with absolute evenness all around till the plant assumes the shape of an egg or a perfect sphere. The only parallel to atrocities of this kind is seen in the work of professional tree-butchers who go about the streets of towns and cities amputating all the branches of the street trees and leaving nothing but forked posts. And yet in many cemeteries and private grounds in city suburbs shrubs are mutilated in exactly this fashion by men pretending to be professional gardeners. Of course all the beauty and grace of the plants are destroyed.

And how about the flowers? A large percentage of flowering shrubs bloom in the spring, and most of these form their blossom-buds on the small branches that were made the year before. In each bud is a flower safely protected from the winter weather and ready to open with the warmth of the coming year. These are the branches lopped off by the shears in autumn or early spring, and with them are sacrificed the buds and promised flowers. If the pruning is delayed after the shrubs have bloomed they will make an effort to repair the loss by throwing out new shoots, which will ripen and bear abundant flowers the next year. In the case of shrubs like the *Althæa*, the Great Panicked *Hydrangea*, and some species of the *Tamarisk*, which bloom in the fall on wood grown the same year, a hard cutting back between late autumn and early spring will destroy no flower buds, but will encourage a strong growth of flowering wood for the next autumn.

Fig. 15.—*Chionophila Jamesii*.

But shrubs, as a rule, are in flower but a short time comparatively, and it is rarely advisable to adopt a treatment which has in view this brief season only. Even in winter a mass of shrubbery has a beauty of its own. Every thicket is enveloped with a nimbus of delicate tints, violet, rose, soft gray and faint olive, which comes from the combined colors of the twigs. This is true not only of those shrubs which have bright colored bark like the crimson of some Dogwoods and the yellow of the Willows. Many others whose single shoots show no striking color on close inspection are surrounded by this halo when they are massed so that the faint tints of each twig are all gathered and fused together. At all events, a mass of this kind is more beautiful than a row of *Althæas* cut back to bare poles. And in the season of foliage a severely pruned shrub is deprived of that flowing grace of outline which is one of its principal charms.

For general purposes, therefore, shrubs should never be cut back so far as to impair their vigor; nor should they be pruned so as to destroy their natural outlines. They should rather have the weak shoots thinned out and be cut back cautiously so as to develop their best form.

Shrubs like Thunberg's *Spiræa*, which bloom early on wood of the previous year, should not be pruned in autumn or early spring where it is desired to secure abundant flowers, but immediately after the blooming season.

Shrubs that bloom late on wood of the current year should be pruned after the leaves fall in autumn or in early spring before they start.

S. A.

The Cultivation of Lilies.

WHAT soils do Lilies require, or in what kind do they best succeed? are questions often asked; and a fitting answer is, that it makes but little difference. The character of the soil is of less importance than its condition. I have planted Lilies in soils varying from the heaviest clay to the lightest sand, and have had perfect success in all. My preference is a light loam, moderately moist and rich, and in partial shade. If that is not at command, I plant in such as I have, with full confidence that a soil which will yield a good crop of garden vegetables will produce Lilies.

It is a mistake to suppose that each plant needs a soil with certain specific characters for its perfect development. It is safe to say of Lilies, at least, that all the species will thrive in the same soil. Make a heavy soil rich and provide good drainage, and you will get an abundance of Lilies. Make a light soil rich and keep it moist by a liberal mulch, and the result will be the same.

A common cause of failure in Lily-culture is planting in wet situations. Too much water around the bulbs in winter is about as injurious as too many degrees of frost. While the Lily prefers a moist and cool situation, it will not thrive where the soil is covered with water during winter.

There are many gardens noted for productiveness which cannot be planted until long after neighboring ones because of too much moisture; such are not suited to the Lily. The remedy in such a case is a raised bed, which may be prepared by marking out a bed of a required size and digging the earth deep. Then on the surface place stones, of about the size used for paving, some ten inches apart each way. Fill the spaces between the stones with soil level with the tops. Upon this place the bulbs, and between them put smaller stones; then cover the bulbs to the depth of six inches with good rich soil. The bulbs should not be placed nearer than one foot from the edge of the bed, which edge should be nicely sodded and kept neatly trimmed during summer. Upon the approach of frost, mulch a little more heavily than if the bulbs were planted in the ordinary border.

With these precautions, nearly all Lilies can be grown in the greatest perfection.

For the perfect development of the flower, a few other precautions are necessary. The first is to cover the bed during summer with some neat mulch, in order to keep the ground cool and moist; this is not only necessary for the full development of the flower, but for the growth of the bulb, and the flowers the coming season will be numerous and strong just in proportion to the size and strength of the bulb formed this year. For mulching, some low-growing annuals should be used, such as Verbenas, dwarf Petunias, or any other that fancy may suggest. This applies only to Lilies in a raised bed; when they are planted in the shrubbery-border, an excellent place for them, this precaution is not necessary.

The second precaution is, to have the Lily-bed partially shaded, to protect the plants from the mid-day sun. This may be done by a light lattice-covering, say three or four feet above the plant; or by arranging a frame with a light canvas covering, to be used only in excessively hot weather. This will not only prolong the season of flowering, but the flowers will be larger, the colors and markings better defined, and the whole plant stronger and more healthy. Of course, good flowers can be produced without these precautions, but better ones can be produced with them.

When to plant is an important consideration. It is well known that the best time to remove plants, and particularly bulbs, is during their period of rest. The Lily has but a short season of rest; it is constantly doing something in the way of development, but its energies are only employed in one direction at one time. The growth of stem and flower consumes the bulb, which, in its turn, is built up by the action of leaf and stem. It is better to transplant as soon as possible after the bulb has perfected its growth. If taken up at this time the bulbs can be packed away in leaf-mold until spring, if necessary. It is far better to take up, separate the bulbs and plant out the same day. Bulbs should remain dry but for a very short period. In importing new varieties and for purposes of sale, it becomes necessary to keep them dry longer than they should be. Every day they are exposed to the air materially weakens them, and often beyond their power of recuperation. No wonder growers get discouraged in their efforts to exhibit a Lily-bed, when they buy bulbs that have been in dry sawdust, or exposed to the dry atmosphere of the seed-room, from October until May. Such bulbs will not recover their strength, if ever, until long after the hopes of the buyer have been blasted, and he has bestowed his blighted affections on some other plant.

When Lilies have become established frequent removals are not desirable; they should remain undisturbed as long as they flower well. It is well to remove the small bulbs that form at the base of the stem in early spring, and transfer them to the reserve ground to complete their growth and be ready for future use.

C. L. Allen.

Seedling Rhododendrons.

I THINK we ought to encourage the raising and planting of seedling Rhododendrons more than we do. By raising them from seeds saved from the hardiest varieties already in cultivation we may reasonably expect a majority of the seedlings to prove hardy. And I have no doubt in point of vigor and health the seedlings have the advantage over the grafted plants. But in the production of flowers I am inclined to think that the grafted plants will bear more than will the seedlings, because, being less vigorous, they are more branchy in proportion to their size, and every little shoot among Rhododendrons should carry a bunch of flowers.

Four years ago last fall we planted a hundred seedlings in one bed. They were then some 20 to 24 inches high, and well set with buds. In spring they bloomed as if nothing had happened, and have ever since grown and flowered most satisfactorily; and all are still alive and in excellent health. Now, the most striking feature about these seedlings is their vigor. They have outgrown a lot of grafted plants that occupy the same bed with them and which are considerably older than the seedlings, and there is more suppleness in their wood and freshness in their foliage than the grafted specimens show. The flowers of all are beautiful—indeed, many of them are as good as those of some of our named sorts. But while these seedlings, so far, have proved hardy here, in less favored localities, no doubt, all of them would not prove hardy. But surely we can raise seedlings that will prove hardy generally from *Everestianum*, *Album elegans*, *Abraham Lincoln*, and other hardy kinds.

We mulch this seedling bed with oak-tree leaves; throw them in loosely among the bushes in fall, and about 12 to 18 inches thick, and leave them there winter and summer. The frost never penetrates through this mulching; nevertheless, although the soil about the roots never freezes, and the tops may shiver and droop in zero weather, I never have known the plants to be injuriously affected by these apparently inconsistent conditions.

W. Falconer.

[The disadvantages of planting seedling rather than named, tried varieties of Rhododendrons, are that more or less of the seedlings prove too tender for our climate, and that many of them produce inferior flowers. For most people, especially for those who only need a few plants, the named varieties will be found the most satisfactory. Layered, and not grafted, plants should be used whenever they can be obtained. They grow better, and are not troubled with the suckers, which spring up from the stock of grafted plants.—Ed.]

Chrysanthemum Notes.—Chrysanthemums from this time will be much better without any fire-heat. There is no better place for them than a cold-frame sunk a foot below the ground level. They should not be set close together—a space of at least an inch between each pot should be allowed. It is not that the plants themselves would crowd each other when closely packed, but each pot will be found to have the roots strong and vigorous around the outside of each ball of earth. They should be covered every night with something more than ordinary glass sash, for at least a month to come, and I know of nothing better than the cloth made by the United States Waterproof Fibre Company. I have frames made to fit sashes six by three feet, covered with the cloth and put on every night, and it is astonishing how much frost they keep out. All plants as they become well rooted should be repotted before becoming pot-bound. The black aphid should be kept well in check. I use, first, wherever practicable, fumigation with tobacco, once every week; then I dust the plants over head with pure tobacco dust. I have found plants injured when using tobacco snuff. Finally I syringe with tobacco-water, made strong enough to have the appearance of black coffee. The white mildew must be fought with sulphur. I mix equal parts of sulphur and very fine flue-dust from hard coal. With this I thoroughly sprinkle the plant above and below and leave the dust on for a couple of days. If at any time it is not possible to repot plants when they become pot-bound, give an occasional watering of liquid manure to keep up the food supply. Do not neglect to keep plants staked as they grow.

John Thorpe.

Acacia pubescens.—This plant was introduced into cultivation a century ago by Sir Joseph Banks, but no one has ever tired of the beauty of a fine specimen when in bloom. Coming from the extra-tropical regions of Southern Australia, it can be kept in a cool house where the temperature does not fall below 40°, and it requires the simplest treatment. It comes into bloom in February and continues to flower from four to six weeks. Although the flowers when cut wither in a few hours, a well grown specimen in bloom is singularly beautiful. I lately saw one that had grown up with a single stem and then spread out into the form of a tree some ten feet high, with broad top and drooping branches. Every twig was thickly hung with pendulous racemes of canary yellow flowers, which showed at their best against the delicate foliage, and made a sight to be remembered long. S. A.

Hardy Rhododendrons.—Let me add to the list of hardy Rhododendrons given in GARDEN AND FOREST of March 14th the names of the following, which come through the winters of this latitude in perfect safety:

Chancellor, dark purplish crimson; Cyanum, bluish white; Gloriosum, creamy white; Michael Waterer, crimson spotted; Minnie, bluish white; Perspicuum, clear white; Pictum, clear white, spotted; Queen, cream, edged with pink, and Oculatum, light pink.

Joseph Meehan.

Germantown, Pa.

The Forest.

Tree Planting in California.

THE following is part of an address delivered before the American Horticultural Society at its late meeting, at Riverside, California, by Mr. Robert Douglas:

The Legislature of the State of California has granted an appropriation for the establishment of experimental stations for testing fruit, ornamental and forest trees. And its citizens generally seem to be awake to the necessity of planting forest trees.

This experimental work cannot be commenced too soon, for while individual enterprise has been employed in thoroughly experimenting with every kind of fruit to an extent which is simply wonderful, the noble indigenous trees of the State have been sadly neglected. In deed, with the exception of a few stately specimens in the Capitol grounds at Sacramento, we rarely find a specimen except the Monterey Cypress (*Cupressus macrocarpa*) and Monterey Pine (*Pinus insignis*) planted everywhere, while specimens of *Sequoia gigantea*, *S. sempervirens*, *Cupressus Lawsoniana*, *C. Goveniana*, *Thuja gigantea*, *Libocedrus decurrens*, *Pseudotsuga Douglasii*, *Picea Sitchensis*, *Abies concolor*, and other noble Silver Firs and Pines are rarely met with.

Forestry is a subject of great importance to this State, and the time will soon arrive when it cannot longer be neglected. The conditions here differ so materially from those of the Atlantic slope that our experience there will not avail us to any great extent here. Forestry here must be confined mainly to desert and hilly lands that cannot be irrigated.

A transient visitor from the East, looking from the window of a sleeping-car, would see a very discouraging prospect. The desert is certainly not promising to him, and the hills look little better. The word, desert, is not well understood. Many agriculturists and horticulturists in Kansas and Nebraska claim that they have brought their land from a desert to rich fertile land within two or three decades. They tell you that their States are a part of the "Great American Desert," and refer you to a school-geography to prove what they say, but they do not seem to notice the fact that in this same school-book there are woodcuts of Indians chasing immense herds of buffaloes, wading through very tall grass.

When the emigration of 1849 went through the Territory of which Kansas and Nebraska is now a part—and that was before there was a white settler in the territory—the land lying between the Missouri River and the Rocky Mountains was called the Plains. The desert of the "Forty-niners" lay between the sink of the Humboldt and the Sierra Nevada Mountains. And many years before that time the Santa Fé traders crossed the Plains from Leavenworth to Santa Fé.

The settlers in Kansas and Nebraska claim that they can grow cultivated crops where they could not be grown twenty-five years ago. This is undoubtedly true and can be readily accounted for.

Before the whites settled west of the Missouri River the land

through central Kansas and Nebraska was covered with Buffalo Grass, which kept the rains from penetrating the ground almost as effectually as would a shingle roof. I have thrust my cane into the ground a few minutes after it has been flooded with rain, and found it as dry as dust two inches from the surface. The rain ran off in torrents into the ravines and "draws" without having a perceptible effect except on the surface. You might see the plains covered with water, looking like a lake with many islands, and within two hours from that time scarcely a sign that there had been any rain at all. Since that time millions of acres have been plowed in Kansas and Nebraska, and, aside from this, 147,000 acres have been planted with forest trees in Kansas, besides a large number planted last year; and a great many more have been planted in Nebraska than in Kansas.

Now, when we consider that an inch of rain is equal to one hundred tons of water per acre, and multiply the millions of acres of plowed land by the number of inches or hundreds of tons that have been absorbed in the plowing, which formerly ran off, we can see that the settlers have materially changed the condition of the plains.

While your desert lands look very unpromising to the tourist, even when compared with the plains, the close observer will see many things, aside from climate, in your favor.

Any one studying these deserts carefully will see that, lying neglected, they must be gradually growing drier and drier. This is plainly to be seen. We see that where deep lakes once overflowed no water stands now. Where monstrous trees once grew, as shown in the petrified forests, only pigmies in comparison grow now. We see that the channels of the streams are gradually being cut deeper, which, of course, drains the country more rapidly.

Although I have not had the opportunities for studying tree-growth on this side of the continent that I have had on the other side, I have yet seen some very encouraging signs. I have seen changes recently in parts of the country I went over in 1849 that are well worth noting and give great promise, even on what were then desert lands pure and simple. On the other hand, I have carefully observed, especially in one or two cases, that among millions of trees covering miles on the side of a desert, I could not find a single tree less than fifty or seventy-five years old, although these trees are covered with seeds and there are no indications of a fire ever having visited them. This is proof, to my mind, that the climate is drier, as seeds cannot germinate now where they produced seedlings less than a century ago.

Any one who has studied these desert lands, even when on a flying trip, will see enough to convince him that if irrigation could be secured there would be very little desert land in this State. I firmly believe that on any desert land where Sage Brush and other shrubs are growing even sparsely, forest trees will grow if the land is cleared and well plowed, which is a very cheap and simple affair compared either with clearing grub-land, timber-land, or breaking prairie in the Eastern States.

The forest trees must be planted during the rainy season, and cultivated at least during the succeeding season. It is surprising to see how the land in this State endures drought when compared with similar land on the other side of the continent. I have seen our gravelly land in Illinois without apparent moisture at three feet in depth after a drought of only six weeks. I have noticed men digging only two feet deep for telephone poles in this State and the moisture was perceptible, although there had been no rain for nearly six months.

This is not a solitary case, but it is usual, as I have frequently noticed in new railroad-cuts. In the East a hard-pan lies at a certain depth from the surface, through which the moisture cannot be brought up by capillary attraction. In this State the soil generally is loose and porous down to the bed-rock, however deep that may be, consequently all the deciduous fruits may be grown without irrigation, but they must be thoroughly cultivated to get the best results.

All through the San Gabriel Valley, and in other parts of the State that I have visited, the indigenous trees thrive best on the north sides of the hills—indeed, the hills are generally destitute of tree-growth on their southern sides, bearing only shrubs, perennial and annual plants, and a scanty growth at that. Yet I have seen Eucalyptus growing, when planted, on the very summits of some of these hills, and on their southern slopes. In very many of these hills the soil is rich enough for tree-growth, even to the very summit—indeed, I do not remember an exception, unless in cases where the rock protruded.

It becomes me to touch the subject of irrigation with modesty, for I received a severe rebuke for the first opinion I ventured to express. A gentleman was irrigating a fine Araucaria; he had the earth scraped away from the collar of the tree, forming

a basin about three feet in diameter and six inches deep; he was flooding this with cold water in the heat of the day, and threw the water with such force from the hose that the crown of the roots was laid bare. I told him I thought he ought not to disturb the surface so near the trunk of the tree, as the feeding roots lay at some distance. He replied that the Mexicans had irrigated for a hundred years, and he guessed they knew more about it than a new-comer. I pocketed the affront, and asked him how long he had lived in the State; he said, over two years. Then I wondered he had not called me a "tender-foot."

No doubt a great deal has been learned from the Mexicans, yet I think our people can soon make improvements on what they learn from them. The more I observe and study this desert question, the more I become convinced that progress will be made in this direction much more rapidly than the most sanguine can imagine. Scientific men may attempt to prove to you that according to natural laws the thing is impossible. Less than fifty years ago they said, and wrote, that valuable trees could not be grown on the Illinois prairies, until many generations of Willows and Poplars were grown to fit the land for the more valuable kinds; and at that time it was the general belief of prairie farmers, that trees and the "tame grasses" would never succeed on prairie lands. Now we know, and have long known, that our prairies grow every kind of tree and grass that will bear the severity of our climate.

You will make much more rapid advances than we made in the Mississippi valley. Our settlers came in covered wagons, yours come on express-trains; you have improved labor-saving machinery, which was not then invented; and last, but not least, you have a stable currency, and are not left to the mercy of wild-cat banks.

Reservoirs will be built to husband the waters that are now running down the rivers into the ocean, artesian wells will be used in many places, thousands of acres of forests will be planted that will not grow as rapidly as if irrigated, but after they are planted and cultivated, the earth will absorb a great quantity of water that formerly ran off. The trees will shade the ground, which will gain in both moisture and fertility, as they will draw nutriment from an immense depth while our forests draw their nutriment from nearer the surface. The eastern farmer and horticulturist has at best only seven or eight months in the year, and from this must provide enough to support his family, and secure fuel and feed for his stock; aside from this his land is decreasing in fertility, or kept fertile at great expense and labor, while yours will, for a long time, be increasing in fertility, if kept well cultivated and worked deep.

It will require more experience than any of us have had, to decide which will be the most suitable trees for forest planting. Many of the most profitable for Eastern planting would not succeed well here. The soft foliage of the White Pine and Larch would unfit them for this climate, and the tendency to run their roots near the surface of the ground would be to their disadvantage. For desert planting, trees must be used that can be grown cheaply from seeds, so as to come within the means of the new settlers. This would seem to be a necessity. I would place the *Eucalyptus globulus* at the head, as I have seen it growing in what would seem almost impossible places. It would make fuel cheaper than any other tree that could be grown on like lands.

The common locust, *Robinia Pseudacacia*, I have seen growing well in western Kansas and Nebraska, New Mexico, Colorado, Utah, Nevada, and at several places in this State, in every case making a good growth without irrigation; and in all these cases I have failed to find traces of the borer, so fatal to this tree in the Eastern States. Would space admit I might name other trees I should deem promising. These two, however, would furnish fuel and durable posts for the new settler, are grown very cheaply from the seed, and transplant well. For general forest planting there are two valuable trees that stand out in bold relief. In this case there can be no mistake, for nature has succeeded in growing them almost everywhere between the eastern bases of the Rocky Mountains and the Pacific coast, and man has used them more generally than any other trees over the whole western half of the continent. These are the Yellow Pine, *Pinus ponderosa*, and the Douglas Spruce, *Pseudotsuga Douglasii*. The former ranges all through the mountains from British Columbia down into Mexico, through Arizona and New Mexico to western Texas, growing on dry mountain-sides through Colorado and Montana. It forms over ninety per cent. of all the timber in the Black Hills of Dakota, reaches further out on the plains than any other tree in Colorado, and is the only Pacific coast tree that runs east into Nebraska.

Next to the Douglas Spruce it is the most generally distributed and valuable tree of the Pacific forests. The Douglas Spruce ranges through British Columbia, Oregon, Washington Territory, all through the Sierra Nevada, the San Bernardino Mountains, Arizona, New Mexico and on high dry ridges in Colorado, through the Uinta and Wasatch Mountains and in Wyoming and Montana. It is called Yellow or Red Fir by lumbermen, is the most generally distributed, and said to be the most valuable timber tree on the Pacific coast.

This tree grows on high dry ridges in Colorado, Arizona and Montana, which proves it to be, like the Pine, a suitable tree for planting on dry lands. Like the Pine, it is a rapid grower and reaches the largest size. These two trees furnish nearly all the merchantable lumber, except redwood, from the coast to the eastern base of the Rocky Mountains.

The *Sequoia sempervirens*, Redwood, is a valuable tree, but only adapted to certain localities. It has a very circumscribed range, only reaching from about the northern line of the State to the southern boundary of Monterey County, and in a narrow belt along the coast. But experiments may prove that this valuable tree will succeed far from its present locality. I noticed a fine specimen in Pasadena, eight years planted and over twenty feet high. *Pinus insignis*, although its timber is of no great value, may be named as having a very limited range—only found in a sandy spot at a single point on the coast; yet we see it growing well wherever planted. We may hope from this fact that other trees of limited range and more value may have their limits extended under cultivation.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—A few years since I met with, in its wild state, a white-flowering specimen (is it a variety?) of *Phlox divaricata*, which was transferred to my wild garden, where it now flourishes. I have been surprised at the remarkable beauty of the plant. As is well known, this species, at least in its wild state, is of a loosely spreading habit, and rather chary of its stems and leaves, whereas the plant referred to forms a luxuriant and well-rounded head, being generous in stems, leaves and branches. The foliage, too, it may be remarked, is of a distinctly lighter shade of green, readily distinguishing it from the usual form. From the middle or latter part of April until after the middle of May it is covered with a snow-white bloom, making it altogether a plant of striking appearance. As neither Gray nor Wood, in their popular Botanies, make mention of a white variety, and having seen no reference anywhere to white-flowering specimens, I am desirous of knowing whether they are of rare occurrence; and if not, why has so little attention been given by cultivators to so ornamental a plant?

Fairview, W. Va., March 20th, 1888.

W. E. Hill.

[The white form of this flower is not unknown in cultivation. It is contained in Woolson's Catalogue this year. Mr. Woolson writes that it has proved unsatisfactory with him on account of its straggling growth. Mr. F. D. Hatfield, of Wellesley, Massachusetts, considers it a good plant for rock-work or the front of a border. Of course single plants make little show, and it should be grown in masses. From our correspondent's description it is not impossible that he has chanced upon a variety of this Phlox which has special merits.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—I was glad to see the recent article in your paper about Sweet Peas. There are no flowers I love better and none which have given me more trouble; and I venture to ask, therefore, whether you will not now kindly give a little advice with regard to the best methods of planting and treating them in this part of the world.

Leesburg, Va.

Dilettante.

[Any fairly good garden soil will give an abundant yield of these flowers if the seed is only planted early enough. This means just as soon as the ground can be worked in spring, a period which comes some weeks earlier in Virginia than in New York. No injury will come from frosts or even ice. Then plant deeply and plant thinly. Have the soil worked to the depth of eighteen inches or two feet, and drop the Peas in a furrow five or six inches deep. Cover at first with about three inches of soil, and, as the plants grow, draw earth up to them until the bed is level. The roots of Peas like a cool place to grow in. Then, if

every flower is cut every day, and no seed allowed to form, the same plants, with good tall brush to run over, will produce flowers until frost. There will be no need of another sowing for succession.—Ed.]

Recent Publications.

Winter: From the Journal of Henry D. Thoreau; edited by H. G. O. Blake. Houghton, Mifflin & Co., Boston, 1888.

Thoreau left behind him at his death a very voluminous journal in which he had noted down from day to day the sights which had met his eyes in the woods and fields of Concord, and the thoughts which they excited in his mind. On one page of this journal he said that it might be well to write "a book of the seasons;" but as he never accomplished this task it was wisely thought that another hand should compile such a volume from the notes which he had jotted down, perhaps in half-conscious preparation for it. Several years ago "Early Spring in Massachusetts: From the Journal of Henry D. Thoreau," was accordingly issued by Mr. H. G. O. Blake; "Summer" followed in 1884, and just now we have been given "Winter" in a similar form.

More delightful books than these it would be hard for the lover of nature to find. Thoreau was not merely one of the keenest and most patient, but one of the most poetic of observers; his poetic instincts were of that philosophizing kind which bring the inmost soul and needs of man into perpetual relation with external things; and his style is almost unsurpassed for clearness, simplicity, individuality and charm. Whatever he saw, he saw with the soul as well as with the eyes; and he saw everything—from the broadest or most fleeting landscape effects to the most tender beauties of the humblest insect, animal or flower. His feeling for beauty was as intense as his delight in the facts of animal and vegetable existence. If he never speaks like a scientific botanist, he always speaks like an accurate observer, yet always, as has been said, like a poet, too. And when he paints for us what he sees, it is in words which sound like the thoughts of an artist translated from paint into language, with a skill of which he almost alone, among writers of English, has found the secret. There is no artifice, and not even any conscious art, in his manner of writing. What we have in these books are simply notes jotted down at the moment, often out-of-doors, and always for his own eye only. Yet take such a passage as this, for example, and try to match it from the pages of any other writer: "Each little blue curl calyx"—he is speaking of a little aster sheathed in ice—"has a spherical button, like those over a little boy's jacket, little sprigs of them; and the pennyroyal has still smaller spheres more regularly arranged about its stem, chandelier-wise, and still smells through the ice. The finest grasses support the most wonderful burdens of ice and most bunched on their minute threads. These weeds are spread and arched over into the snow again, countless little arches a few inches high, each cased in ice, which you break with a tinkling crash at each step. The scarlet fruit of the cocksaur lichen, seen glowing through the more opaque whitish or snowy crust of the stump, is, on close inspection, the richest sight of all, for the scarlet is increased and multiplied by reflection through the bubbles and hemispherical surfaces of the crust, as if it covered some vermilion grain thickly strewn. The brown cup lichens stand in their midst. The whole rouch bark, too, is encased." This for a microscopic picture; and this for a broad landscape effect: "A beautiful, clear, not very cold day. The shadows on the snow are indigo blue. The pines look very dark. The white-oak leaves are a cinnamon color, the black and red oak leaves a reddish-brown or leather color. A partridge rises from the alders and skims across the river at its widest part, just before me; a fine sight. How glorious the perfect stillness and peace of the winter landscape." To quote from the more human, more philosophical parts of this volume—parts which recall the writings of Emerson in a way which does but accent their own individuality—would be out of place just here. But intermingled as these are with his manifold, exquisite pictures of plant life and of landscape beauty, they do much to make up the charm of Thoreau's most charming book.

In the *Popular Science Monthly* for April will be found a chapter on "The Earliest Plants," extracted from Sir William Dawson's recently published "Geological History of Plants," and further back in the thirty-second volume of the monthly—is a discursive article by Grant Allen on "American Cinquefoils," and one on "Our Forestry Problem" by Mr. B. E. Fernow, Chief of the Forestry Division of the Department of Agriculture.

Retail Flower Markets.

NEW YORK, April 6th.

The trade in plants and cut flowers was very large at Easter. Prices held at a reasonable figure, only selected Hybrid Roses and "Longiflorum" Lilies being somewhat higher, and these only in certain localities. This week there is a glut of cut flowers, and prices are low. The choicest specimens of Hybrid Roses with stems half a yard long, sell for 75 cts. each. Madame Gabriel Luizet Roses are inferior in quality and cost \$6 and \$7 a dozen. Prime Puritans bring \$9 a dozen. Extra fine La France Roses sell for 40 cts. each, and those not so large for \$2 and \$4 a dozen. Ulrich Brünner is exceptionally handsome and costs \$6 a dozen. Selected Jacqueminots are \$6 a dozen, but the majority sell for half that price. The best Catharine Mermets bring \$2 a dozen, and Brides can be had for the same money. Perles des Jardins of excellent quality cost \$1 a dozen, as do selected Niphotos. Mignonette is abundant, a bunch of a dozen spikes costing 50 cts. The Giant variety brings 15 cts. a spike. Lilac holds firm at 50 cts. a spray of two tassels. Violets are of good quality, the Marie Louise bringing \$1.50 a 100 and the single Russian 75 cts. Gardenias cost 25 cts. each. *Narcissus Poeticus* is \$1 a dozen. Daffodils, Lilies-of-the-Valley and Tulips bring from 75 cts. to \$1 a dozen. *Lilium longiflorum* is much preferred to *L. Harrisii*, and brings 40 and 50 cts. a flower where the latter are sold for 30 and 35 cts. Callas bring 25 cts. each. Cyclamen plants averaging twelve flowers are offered for 75 cts. A number of Easter weddings in prospect will keep up a demand for specimen blooming plants and choice cut flowers, Lilies-of-the-Valley in particular. This, with La France Roses, is ordered extensively for ornamental curtains. The steamer trade is just opening, and this will also help to make business brisk.

PHILADELPHIA, April 6th.

Flowers and flowering plants were in greater demand than usual at Easter. *Lilium Harrisii* and *L. longiflorum* were in fine condition, averaging more flowers to the plant than have been seen here before, at prices ranging from 30 cts. to 50 cts. each. None of the leading florists had trouble in disposing of their stock at the highest figures. *Hydrangea Otaksa* and Thomas Hogg were very plentiful; the latter variety, which is a white one, seemed to sell the most readily. Plants growing in 6 and 8-inch pots, with from four to eight well-developed heads, sold at from \$1 to \$5 each. Hybrid Remontant Roses in pots would have been more plentiful but for the dull weather in the early part of the preceding week. Most of them were growing in 6-inch pots and sold at from \$1 to \$1.50 each. Fine Azalea plants, half standards, sold at from \$2 to \$10 each, and very large ones were in demand at as high as \$20 for special occasions. The customers at this great floral festival have very little choice, as the demand is so great that they must take what they can get. Six-inch pots full of Daffodil Van Thol were plentiful and in demand at from 50 cts. to \$1 each. *Gardenia florida* (Cape Jessamine) as a pot plant was a novelty here. That is to say, it was scarce and had not been seen on these occasions for some years past. The price varied from \$5 to \$7.50 each. Most of them were growing in eight-inch pots and were from three to four feet high. Hybrids were from \$4 to \$6 per dozen, excepting some special sorts like Madame Gabriel Luizet, which reached the highest figure at \$7.50 per dozen. Jacqueminots were in as great demand as usual at from \$3 to \$5 per dozen. There is a falling off in the demand for designs. Churches were profusely decorated, but without novel features. There is very little leisure for a study of novelties in decorations at this busy season. Some few Genistas in pots, both large and small, proved useful for decorating and sold readily. Tulips, Lilies-of-the-Valley, Daffodils, Freesias and all varieties of Roses, were abundant, and sold at very good, though not exorbitant, prices.

BOSTON, April 6th.

Easter Sunday and the two preceding days were perfect spring days, and in the bright weather the flower trade was unusually brisk. Never before were so many flowers sold in Boston for Easter. There was no scarcity, however, and prices were therefore reasonable. The White Lily was the single exception, being in short supply, and late comers were obliged to accept substitutes. After the Easter rush there has followed a lull, but many fashionable weddings and other social occasions are in prospect, and all signs point to a large consumption of flowers this Spring. Roses are still abundant and of superb quality. Jacqueminots and Hybrids of enormous size, and with stems two feet or more in length, are to be seen in all the fashionable florists' windows. These bring from \$4 to \$8 per dozen. The longest stemmed flowers always bring the highest price. Mermets, Marechal Neils, Bennetts and Perles are abundant, and are offered as low as \$1 to \$1.50 per dozen. There are a few Lillies at about one-half of the Easter prices. Smilax is very scarce, and the little that is offered is poor in quality. Long-stemmed Carnations are 50 cts. to 75 cts. per dozen. Violets and Pansies, \$1.50 per hundred. For mixed collections of cut flowers there is a great variety of bright and fragrant blooms, such as Lilies-of-the-Valley, Tulips, Daffodils, Mignonette, Forget-me-not, Heather, Heliotrope, Marguerites, etc., with fine Maiden Hair Ferns and Asparagus for green. A bunch of "Pussy Willow" laid on a box of selected flowers gives a pretty finish.

Tree-planting.

THE operation of planting trees requires deliberation and care. It should be done thoroughly or not done at all. Economy in tree planting means the proper preparation of the ground to be planted, and the use of well selected and well grown trees. The insufficient preparation of the soil and the use of badly-grown and badly-rooted plants is extravagant and wasteful, because such a course must invariably fail to produce satisfactory results. William Cobbet, who more than sixty years ago wrote what still remains the best book on planting which exists in the English language, exclaims, in speaking of the necessity of a thorough preparation of the soil, "How many millions have been *thrown away* in planting! How many thousands of plantations have, at the end of twenty or fifty years, made a beggarly exhibition; and how many of them have wholly failed! Yet, no truth is more evident to my mind than this: that no plantation ever failed, except from the manifest error of the proprietor. It is worse than useless to plant, unless you do the *whole thing well*; because, instead of creating a source of profit and of pleasure, you create a source of loss and mortification."

Trees may be planted in this latitude in spring or in autumn; in more northern parts of the country they can be safely planted only in spring. Whether they are planted in spring or in autumn the ground should be prepared in advance. This should be done for spring planting the year before. This will give time to the soil to settle and become pulverized, and it will enable the planter to consider carefully what trees he will plant and just where he wants to set them. These are questions which should not be left unsettled until the short planting season arrives. The composition of an ornamental plantation—that is, the proper grouping together of different varieties of trees in a harmonious arrangement—requires much consideration and study. Satisfactory results will never be obtained if the arrangement of a plantation is left until the trees arrive on

the ground. The proper preparation of the soil is the foundation of good planting. The best results will be attained by trenching by hand the area to be planted to a depth of two feet. The ground in this way is thoroughly broken up and loosened and the roots of the trees can extend freely in all directions. Care must be taken in trenching to keep all the surface soil on top and not to mix it with the subsoil. Hand trenching is a slow and expensive operation, and few people will undertake it on a large scale in this country. When the ground is not trenched a hole must be dug for each tree. The larger and deeper they are made, the better the trees will grow. Holes twenty feet across and three feet deep are not too large, if large, long-lived and healthy trees are expected. It is impossible to provide too much healthy nourishment for a tree. Small and shallow holes mean small, stunted and short-lived trees. All holes for spring planting should be dug during the previous autumn. As soon as dug the loam should be put back in the holes, and if the land is gravelly or rocky the poor soil should be replaced by loam or peat carefully mixed through it. Peat furnishes valuable food to trees, and almost all varieties enjoy a liberal supply of it. The soil will be thoroughly settled in the holes by spring and all ready for planting, and the small, shallow hole actually necessary to receive the roots can be made then easily and quickly in the prepared soil.

It is always better to plant small trees than large ones. They are more easily and cheaply moved, recover sooner and grow more rapidly. A transplanted tree two or three feet high will soon overtake and surpass a much larger one, and will grow into a more vigorous and beautiful specimen. A vast amount of money and a great deal of time is wasted every year in trying to transplant large trees.

It is not essential in digging up trees to preserve a large ball of earth about the roots. A very heavy mass of earth often breaks the tender roots, and is, therefore, a danger rather than an advantage to the tree. It is essential, however, to preserve as many of the small feeding roots as possible, and care must be taken in digging a tree not to unnecessarily break or mutilate them. All broken roots should be carefully cut away with a sharp knife before the tree is replanted. Care must be taken not to expose the roots to the drying influence of the sun and wind. They should be covered as soon as the tree is dug with a piece of cloth or matting, or they may be dipped in wet mud until they become thoroughly coated. The secret of successful transplanting is to have the soil brought into close and immediate contact with the roots. It is better, therefore, to plant in dry, and not in wet, rainy weather. The coating of mud not only protects the roots from drying, but helps the earth thrown about them to adhere more closely. Two men are required to plant a tree. The hole should be twice the width of the mass of roots, and the bottom should be worked fine with a spade. One man should then hold the tree erect, with its roots carefully spread out in all directions in the hole, while the second man should break the soil taken from the hole, so as to make it as fine as possible, and then let it fall from the spade down upon the roots, while the first man should lift the tree gently up and down that the fine earth may penetrate and fill all cavities about the roots. When the hole is nearly filled in this way the earth should be pressed down with the foot, beginning at the outside of the hole and working in towards the stem of the tree. The hole may then be filled and the soil rammed down solid. Tall trees should be carefully and securely staked as soon as planted. The operation is then finished. It is not uncommon to see water poured into the hole while it is being filled up. This practice does harm rather than good, as it washes the fine soil away from close contact with the roots.

Some planters recommend transplanting coniferous trees during the month of August, but this plan has little to recommend it; and it is certainly safer to move them in the spring. Many people believe, too, that they can only be safely moved late or after they have begun their annual

growth. This is a mistake. Conifers can be safely transplanted just as soon as the soil is dry and friable. They can, however, be moved later than deciduous trees, as they begin to grow later.

These are the general rules for successful tree-planting. Certain families or species sometimes require special treatment. Magnolias should be moved late, and after their roots are in active operation, which is shown by the unfolding of the leaf buds. Walnuts and Hickories, as they have strong, deep tap-roots, should, if they are to grow into fine trees, be planted when very small. Seedlings two or three years old, when finally transplanted, make the best trees. All the Oaks make better trees when permanently planted young. This is true of all the White Oaks. Some of the Black Oaks, however, especially the Red Oak and the Water Oak, can be safely transplanted, if they have been properly grown in nurseries, when they are ten or twelve feet high. Shallow rooting trees, like the Maples, Lindens and Elms, may be moved, with proper precautions, after they have reached a considerable size and age. Small specimens, even of these trees, move better, however, and in the end give better results and more satisfaction.

The man who plants one good tree thoroughly well, and then takes care of it after it is planted, does more for himself and the community in which he lives, than the man who sets a hundred, badly selected and badly planted, or who neglects his trees after he has planted them.

An American School of Forestry.

AN article on another page of this paper gives an example of the close measurements and calculation that are made by expert foresters in countries where every bundle of faggots is taken into account in estimates of forest production. Under such conditions the theory and practice of forestry are brought to a mathematical basis, and the business of the forester not only embraces the art of growing trees and forests, and of utilizing and disposing of wood products, but it necessitates accurate financial calculation, so that the largest possible production may be made with the smallest outlay. The accomplished forester in Germany must be a financier as well as a mathematician, for, practically, he has the handling of large capital invested in wood production. And since the margins are narrow, the time over which the operations extend long and the factors which enter into the calculation variable and uncertain, there must be frequent measurement and constant adjustment and readjustment of the elements of the problem.

It is plain that America offers no field for those refinements of forest practice. So long as there are vast areas where wood can be had for the chopping there will be no call for experts to estimate laboriously the exact amount of increase on a given area of woodland in a year or in a decade. This does not imply that no system of forestry is possible in the United States, but that for the present, at least, it must be a different system. What is known as "intensive farming" would be folly on a western prairie, but agriculture is profitable there, nevertheless, when conducted in a cruder way, or on the only system practicable under the circumstances. The time may come, as a closer husbanding of natural resources is demanded on what are now cheap lands, when every rood of farm land will become as productive as a garden spot. In like manner the time may come when the same care will be given to the details of forest management here that is devoted to them in Germany to-day, and until some progress is made in that direction there is no encouragement here for a young man to study forestry. This is one calling for which no opportunity or opening presents itself in the United States. Nowhere in the whole country is there assured employment for a single trained forester.

Of course no skilled foresters will appear until there is a demand for their services, and there is but one source from which that demand is likely to come for some time, at least. In spite of the unchecked spoliation of our public timber lands, the Government still owns vast forest tracts, situated largely at the sources of our most important rivers. It is true that our national forest policy, so far as any settled policy exists, seems to have been framed for the encouragement of fraud and depredation. But it must be assumed that an awakened and instructed public sentiment will soon force Congress to make some honest effort for the preservation of the public forests. With the effort will come the need of guards and inspectors, whose duties at first will be to protect the timber from fire and thieves and devastating animals. Even an unskilled patrol, if free from political favoritism, and efficiently organized, would save for the country every year many times its cost. But it would soon be evident that for a reasonably successful forest administration, the service, and especially its higher executive positions, would need officers with a special training.

For this purpose, if the highest efficiency were desired, an American school of forestry would alone suffice. There are laws of plant growth and principles of forest management which hold good the world over. But even from a cultural point of view the American forester would need to be learned in American forest-botany and familiar with the modifications of general practice which our climatic peculiarities necessitate. Besides this, he should be familiar with our business usages and our habits of thought in political matters. Years must elapse before a corps of teachers can be gathered and students graduated. And why should such a school attract students, so long as years of thorough training give no assurance of employment?

In a paper read before the Massachusetts State Board of Agriculture last winter it was suggested by Mr. John Robinson that a United States School of Forestry should be organized and conducted on precisely the same principles as the United States Military Academy. Students should receive an allowance from Government just as the Cadets at West Point do. The course should be thorough, extending over a period of from five to eight years, and a permanent appointment in the Forest Service, with opportunity for promotion, should be given to each graduate. In no other way, so far as we know, can young men of intelligence and ambition be induced to devote themselves to the study of forestry as a profession. An assured and honorable position for life ought to prove an adequate attraction. And in no way can the Government be as certain of a Forest Service of a guaranteed quality and with a proper *esprit de corps* as when it educates its own officials and has the power to prescribe examinations for a commission as rigid as those at West Point.

Easter Flowers in New York.

A FEW years ago our churches were decorated at Easter with great numbers of "made pieces"—crosses chiefly—often of very large size; and their display in the shops on Saturdays attracted crowds of gazers. Now such pieces are scarcely ever ordered. The churches are decorated with growing flowers set against a background of palms, and with quantities of Sm lax and other vines. The fact certainly shows an improvement in taste; and it is also pleasant to note that Easter flowers are no longer sent to the churches only, but are very common as gifts to friends.

The sale was apparently large this year, but the flowers and plants themselves were by no means so good as in some former seasons. The florists explain this fact, however, by reference to the early date upon which the festival fell and the dark skies which have ruled for the past few weeks. The best things to be seen were, perhaps, the Lilies, which appeared in great quantities and in several

varieties—the finest being the tall, white Japan Lily. The florists' habit of removing the anthers from Lilies as soon as the buds open does indeed preserve the purity of the petals; but this gain is somewhat dearly purchased by the lack of their yellow accents when the flower unfolds. Next to the Lilies should be named the Canary Broom, which was grown—and very well grown—in much larger quantities than ever before. Acacias were also for sale, but not in large number. In two or three shops there was a comparative novelty in the shape of great sprays of purple Bourgainvillea. The European Bladder-Nut—a shrub with white flowers—had also not been so often seen in previous years. Lilacs were poor—nor are they ever so good in this country at this season as in Paris, where they are so admirably and profusely forced. Hydrangeas, on the other hand, were excellent and seemed to contest with Lilies the first place in popular favor. Azaleas were very poor—usually both small and badly grown. Spiræas and Deutzias were fairly good. In one shop at least there were a number of Mahernias, not very attractive to look at, but of delicious odor. Orchids, both cut and growing, were conspicuous, and in some cases very good. Daffodils could be had in quantities—not of the first quality—but no other variety of Narcissus. Lilies-of-the-Valley and Mignonette were abundant and excellent, Carnations abundant but not fine, and Roses by no means up to the standard of former years. Smilax was everywhere in quantities and excellent in quality.

Dangers threaten the Adirondack forests from every direction. On the 20th of March Mr. Hadley introduced into the Assembly, and, by the unanimous consent of that body, passed to a third reading, a bill authorizing the Commissioners of the Land Office to release and convey to Charles W. Durant, Jr., a tract of land on Racquette Lake one hundred and sixty acres in extent. This piece of land contains some of the most beautiful building sites in all the North Woods, and has a large market value. Mr. Durant entered and took possession of the land, and, without right or title to it, erected permanent, and, probably, expensive improvements, "in contemplation of purchase," the bill explains. Mr. Hadley's bill should be defeated, and Mr. Durant and every other person unlawfully occupying State forest-lands should be compelled to vacate them forthwith. The tract of land which Mr. Durant seeks to obtain by this piece of special legislation is situated within the forest-preserve. The forest-preserve was created and is maintained to protect the rivers and regulate the sanitary conditions of this State, and not to supply homes to wealthy citizens who may take a fancy to pass a few weeks in the woods during the summer months. We have already pointed out in an earlier issue the dangers that menace the forests through the probable enactment of a law giving the Forest Commission authority to lease parts of the preserve for building purposes. The fact that a bill authorizing the sale of a part of the forest to Mr. Durant can be hurried to a third reading in the Assembly without exciting public attention and alarm, shows how great the danger of giving such remarkable and unusual powers to the Commissioners really is. Every one who takes a lease of a piece of land in the forest and makes improvements on it, and then becomes dissatisfied with the terms of his lease, or is unable to renew it, or takes a fancy to own the land upon which he has built, will go to the Legislature to get authority to buy. And in nine cases out of ten the application, if it is backed with sufficient money, or political influence, or social standing, will succeed.

The Forest Commissioners are opposed, it is reported, to the passage of the Durant bill, although it is not apparent that they have taken any very active steps to defeat it or to warn the public of this new danger to the forests. Indeed, the favorite measure of the Commissioners, authorizing the lease of State lands for a term of years and with privilege of renewal, practically empowers them to do for a thousand squatters what this bill does for one.

Landscape Gardening as a Profession.

MUCH has been written of late with regard to the opening for young men of ability and taste in landscape gardening. While it is true that the need exists for men of artistic taste and skill in this profession, it is not so clear that there is sufficient encouragement for such men to enter it. The greatest need is for the education of public taste in garden matters, so that the demand for men of trained hand and a correct knowledge of beautiful forms and combinations of flower, shrub and tree may be created. So long as the public are satisfied with parks constructed by engineers, and with terraces and embankments like those of railways or fortifications, and are content to have their private grounds filled with meaningless "serpentine" walks, by some Irish laborer; so long as the denizens of our cities give annual employment to a crowd of peripatetic tree-butchers in lopping off the heads of beautiful trees, just so long will men of taste avoid a profession in which they would starve, while the ignorant pretender and the mathematical park-maker waxed fat. In one of our large Atlantic cities, a recently founded public institution stands at the junction of two wide avenues with ample grounds and grand old trees. The grounds were beautiful and natural before the erection of the institution, but it was thought necessary to "improve" them. And the improver went to work with transit and level, spade, pick and shovel, and he terraced the place on all its public sides with banks one above the other in diminishing perspective, building stone walls around trees from which he dug the earth, until now quite a respectable fort appears, and the passer-by involuntarily looks for the barrette guns on top. And yet the public think it beautiful, and the newspaper men praise the ingenuity in saving the trees. In all our wide and wealthy land the men of true skill in landscape art who meet with encouragement in their profession, can be almost counted on the fingers of one hand, while railroad engineers, architects and hod-carriers are the landscape gardeners for the masses. Political favoritism also operates largely against true landscape art. No matter how correctly some public ground may be designed by its projector, the mutations of politics surely bring in some pig-headed fellows, who either prevent the design being completed, or let some ignoramus spoil it. One has only to go to the public grounds in Washington to see plenty of such examples. The work of A. J. Downing is being allowed to grow into a jungle because no one has had backbone enough to cut away trees which Downing planted as "nurse" trees, while his design was growing. And in the grounds of the Agricultural Department, well laid out originally, and planted as an arboretum, a straight avenue of asphalt has been cut through the original design, and bordered by two lines of wretched Ginkgo trees, looking like foreign tramps in rags and tatters on dress-parade. So long as public taste demands that every little spot of greenery must have all the repose driven out of it by obtrusive beds of Coleus and Geraniums, and the construction of carpet-beds is considered the highest style of garden art, it will be hard to get young men of education and taste to enter into competition with the crowd which suffices for the public demand. Of course, there are exceptions to all this, for we have some good landscape gardeners, and some men who are employing them, but I fear that the few who do really good work can easily do all the good work called for.

HORTICOLA.

["Horticola" is certainly justified in feeling discontented and even indignant with the present condition in our country of public taste in regard to landscape gardening. It is only too true that natural beauty is often, desecrated and existent works of landscape art destroyed by ignorant remodeling, and that the engineer on the one hand or the laborer on the other, is often intrusted with work which demands an artist's eye and touch. We believe, however, that there has recently been an awakening of intelligent public interest in the subject. The fact seems

proved by many other signs as well as by those recently published articles in popular periodicals, referred to by "Horticola," which have stated our need for more professors of the art. The laws of supply and demand are not always easily followed in their working. It is hard to be sure whether "Horticola" is right in believing that so much gardening work in America is bad because we do not appreciate good work, or whether we are right in believing that it is bad largely because enough men cannot be found to do it well. Yet some evidence of the correctness of our belief would appear, we think, if the three or four most prominent landscape gardeners of the country were questioned with regard to their experience during the last ten years; we think they would unite in saying that they are much more busy to-day than they were ten years ago, and that their clients show a more intelligent interest in their labors. We think also that they would recommend their profession as a good one for young men to enter, who are willing to study it thoroughly and are possessed of the energy and enthusiasm necessary to win success in a career which demands practical common-sense united to artistic feeling; for, even though the demand for the services of such men is not nearly so great at this moment as it ought to be, yet by the time a student now commencing his education is ready to begin independent practice, it certainly will be much greater. Of this we feel sure, not only from indices found in the most recent history of the art of landscape gardening itself, but from the records of the development, during the past two decades, of American art in other directions and particularly in the direction of architecture.—ED.]

A Temple in Japan.

THE love of the Japanese for nature and their skill in horticulture are well known. But the high level of their attainments in the art of landscape gardening is, perhaps, less generally understood. From the witness of many travelers it seems to be indisputable that no other people has ever approached this art in so artistic a spirit, has so well known how to improve without disturbing the beauties of nature, or has so persistently and universally put such knowledge to use. Formal gardening effects are never desired in Japan—a fact which might be anticipated by any one who has studied Japanese art in any of its branches, since its very essence is a dislike for formality and symmetry, a love for the utmost variety in detail which can consist with unity of general effect. Japanese art in landscape gardening is pre-eminently the art which conceals art. Every foot of the ground in the more closely populated districts has been carefully tended and treated for many generations, yet there are few spots in which the traveler can decide how much is due to nature's work, how much to man's. Trees and shrubs and flowers, water, and even rocks are sedulously tended with an eye to the production of the highest possible degree of beauty, yet always in such a way that beauty shall seem to have come of itself. Even in the immediate neighborhood of Japanese buildings the same ideal is preserved, and as the architecture, compared with that of occidental countries, is of an unambitious kind, and as the material used for it is wood, the effect is always what we would call a rural, a picturesque effect.

The illustration of a Japanese temple herewith given may serve to give an idea of Japanese architecture in combination with landscape. The temple is placed so that those who visit it have an unobstructed view of the sea and of the beautiful line which the shore makes towards the right, while the precincts themselves are agreeably shaded by large trees, beneath which grass and flowering plants grow in natural profusion. It is needless to point out how picturesque, yet harmonious and graceful, are the forms of the trees—forms not more beautiful in themselves than appropriate as making a delicate frame for the distant stretch of sea. As has been said, it is impossible in Japan to tell in how far any beauty is due to nature, in how far to man. But we may safely conclude that the forms of these trees are not altogether natural—that they have been watched and directed year by year until the most desirable effect was produced and then carefully preserved in that effect. We may even feel sure that the round-headed tree in the far distance would not stand where it does

had it not been felt that its presence was fortunate as accenting the projection of the shore. Color always aids form in producing beauty in Japan. The temple here is painted red and has a roof of yellow thatch, and these tones, in contrast with the dark green of the surrounding trees and the brilliant blue of the sea, must give the spot extraordinary beauty.

Such a picture as this is well worth careful study by those who are meaning to build on the pine-grown coasts of New England. Scenes, the natural beauty of which is closely akin to the beauty of this temple-site, are very frequent there, and the utmost effort should be made by architects and owners, to preserve their charm, to build in such a way that the work of architecture will complete instead of hurting it.

Spring in Mobile.

IT was no later than the middle of February when the red and purple of Verbenas, Drummond's Phlox and Pansies brightened the beds where white Alyssums, Candytufts and Narcissus had already been blooming. Of woody plants the Chinese Cunninghamia, the purple Magnolia, the Laurestinus and the Mahonias were blooming early in the month, followed soon by the Mock Orange and Red-bud from more northern woods, and the Chicasa Plum, whose true home is probably two degrees further north and on the western bank of the Mississippi.

Towards the last days of the month the Loblolly Pine, the Liquidambar, the Hornbeam, and the Sweet-leaf (*Symplocos tinctoria*), one of the prettiest amongst the small evergreen trees of the South, were in bloom. The flowering of the Witch-hazel at this season is worthy of note. Clusters of apetalous, staminate flowers make their appearance in the axils of the leaf buds while still in their winter sleep. Not a single perfect flower was observed, which cover the branches late in the fall with their strap-shaped petals.

In the garden, the Banksian and Marechal Niel heralded the season of Roses by blooming in the first week of March. The dwarf Almond, and the interesting Texan Buckeye (*Ungnadia speciosa*), were by the 12th covered with flowers, while the Hybrid Rhododendrons in many varieties displayed their resplendent shades of purple and red. Azaleas, Rhododendrons and Kalmias were blooming in the forests by the middle of the month, and the swamps were brightened by the flowers of Wax Myrtle, of Andromeda and of the Parsley Haw.

Not to name a score of beautiful herbaceous plants and small trees blooming in the Pine-openings, I cannot pass by the southern Sloe (*Prunus umbellata*). This is one of our most striking trees, and its value for the adornment of park and lawn is not appreciated. At its full growth the trunk is from 8 to 10 inches in diameter, and the tree attains a height of over twenty feet. The massive limbs spread horizontally at a distance varying from 3 to 6 feet above the ground, producing numerous erectly spreading branches, which divide into a mass of densely crowded spiny branchlets, forming a dome-shaped head often over twenty-five feet through. In its season this is covered with snow-white flowers, which are succeeded by dense green foliage. The fruit is of the size of a cherry, deep purplish-blue in color, and used for making an excellent conserve.

Almost all of the ament bearing trees found in this section are now blooming. The Beech, the Cottonwoods, the Black Willow, the Swamp Ash and all the Oaks of the upland and lowland, are unfolding their foliage, while on our porches the Wistaria and Trumpet Honeysuckle are loaded with flowers.

March 26th, 1888.

Karl Mohr.

Foreign Correspondence.

London Letter.

ON March 13th the Royal Horticultural Society met for the last time in its old home, so long identified with the history of English Horticulture, and the occasion brought together a large gathering and an interesting exhibition.

Among the new things exhibited but few were officially approved. The most important plant to receive a first-class certificate was a newly introduced Bladderwort (*Utricularia rhyterophylla*), which will prove valuable for a stove or Orchid-house. In growth it resembles the white *U. montana* and the mauve-tinted *U. Endresii*, the leaves being long and narrow, but the flower spike is taller and more erect. The flowers, in shape so much like an Orchid as to deceive many persons, have

two petals, the broad one resembling a lip about an inch wide. The color is a bright purple, intensified by the rich blotch of orange yellow on the lip. It is a plant of singular beauty, and those who love Orchids must admire this Bladderwort. Fortunately it requires the same treatment as many Orchids, being best grown in a suspended basket in an intermediate house. It is a native of tropical South America. Sir Trevor Lawrence showed the specimen.

A new single white Violet, called The Bride, exhibited by James Veitch & Sons, also won a certificate. It flowers profusely, small plants showing masses of pure white and fragrant bloom. The large and abundant foliage indicates a plant of strong growth and of good promise for market purposes.

A modest little Rock-Saxifrage, with cushions of primrose yellow flowers, won the third certificate. It was named *S. Frederici-Augusti*, but it may prove identical with or a form of

Among a group of plants from Veitch's nursery were three indispensable kinds for the green-house in March. One was the Rhododendron Early Gem, a hybrid from the early flowering *R. Dauricum*, but very much superior in every way. The plants shown were only about a foot high, but were smothered with bloom, each flower being two inches across and of a rich violet purple. It has been known here for some years and is popular among gardeners, as it requires but little or no forcing, and a group of a dozen plants makes a fine effect.

Another early shrub was *Azalea altaclerensis*, an old variety raised at Highclere, the Earl of Carnarvon's estate in Berkshire, famous for the Rhododendrons and other hybrids raised a generation ago. This Azalea is similar to the well-known *A. Pontica*. The flowers are large, of a bright clear yellow borne in large clusters, and rendered most effective by the tender green of the new foliage. The third is the new *Boronia heterophylla*, a native of Australia, one of the so-called New Hol-

A Temple in Japan

S. luteo-purpurea. It is a charming little plant for an open rock garden, as it flowers profusely in defiance of frosts and snow, and so does *S. Burseriana*, which was shown beautifully by the same exhibitors, Paul & Son, of Cheshunt. Among other exhibits not certificated there was the new Rose, Lady Alice, a paler flowered sort than Lady Mary Fitzwilliam, one of Bennett's seedlings, from which it is a sport. The flowers are more globular, and the tint is a delicate blush, just a shade away from white. It is extremely floriferous; so much so, indeed, that, like its relative, it does not make growth enough for the nurserymen. Mr. Paul tells me that the plants he showed, a dozen in number, all with several fine flowers, were from a lot taken into a slightly heated house in December, where, for the past six weeks, they have been supplying cut blooms. A miniature Rose, called Red Pet, also new, was also exhibited from Cheshunt. The flowers are small, but abundant, and the color, a rosy crimson, is bright. Being very dwarf, it is well adapted for pots in the green-house in spring.

land plants. The plant most nearly resembling it is *B. elatior*, but this novelty is finer in every respect. The growth is slender, yet bushy; the flowers, like tiny bells, are of a brilliant carmine-crimson and hang on the erect branches so thickly as to obscure the narrow leaves. I consider it one of the finest green-house plants introduced for many years. If hard-wooded green-house plants find much favor in the United States, this should be remembered as one worth having.

Among the Orchids the most remarkable were the following: *Phajus tuberculatus superbus*, a truly superb variety, having larger flowers than those of the species and with broader and whiter sepals and a more richly colored lip. The new *Angraecum Sanderianum* was shown to perfection by Sir Trevor Lawrence, the plant having four spikes nearly a foot long of snow-white flowers, showing how wonderfully free it is in flowering. But the finest Orchid in the show was *Cryptopodium Saintlegerianum*, which much resembles the old plant named by Lindley *C. punctatum*. It bears a huge branched panicle of flowers, each

one and a half inches across, with yellow sepals and petals, heavily barred with brownish red and a lip of the same color but of a richer tint. It is extremely showy, and, I am told, is not a difficult plant to manage in an intermediate house. It was introduced from Brazil a few years ago by Horsman & Co. through a collector named St. Leger. There were numbers of other Orchids shown, including, of course, many new hybrid *Cypripediums*, for novelties in Lady's Slipper Orchids come nowadays as frequently as new *Pelargoniums* formerly did. Some of them might well be classed as Orchid rubbish, but quite worthy of notice was a specimen of *Dendrobium Wardianum*, fully four feet high by two and a half feet across, with each stout stem completely wreathed with bloom. Every Orchid grower knows that such a specimen requires a deal of skill to grow it, and a cultural commendation was justly accorded to the exhibitor.

Wm. Goldring.

New or Little Known Plants.

Cypripedium fasciculatum.*

WE have had occasion already to refer to the difference which often exists between the eastern and western representatives of the same genus. In *Cypripedium* we have another instance of the same kind, and one which tends to illustrate also how in some measure the flora of northern Europe and Asia and that of eastern North America including Mexico are more nearly related to each other than either is to the flora of California and the Pacific coast. All are familiar with our common eastern Lady's Slippers, which have for the most part leafy stems bearing one or two or rarely three flowers with a conspicuous and usually large white or purplish or bright yellow lip. None of these range as far west as the Rocky Mountains, in which, as in the broad interior region beyond, within the limits of the United States no species of the genus is found. The several Mexican species are of the same general character, with large flowers, as are also those of the temperate region of Europe and Asia.

On the Pacific coast there are four species, one of which is here figured. This, it will be noticed, is peculiar in its single pair of cauline leaves, and in its very small greenish flowers, which are usually several in number and somewhat clustered at the top of the stem. In its foliage it resembles the subarctic *C. guttatum* of Alaska and northeastern Siberia, which, however, has but a single and a rather larger flower. *C. fasciculatum* is found in the Cascade Mountains of Washington Territory and southward in the mountains to Lassen's Peak in California. Its lip is less than half an inch long, and the sepals and petals are not greatly longer. *C. Californicum*, of which a figure will be given in a future number, has a leafy stem with small flowers solitary in the axils of several of the upper leaves, and the greenish yellow sepals shorter than the lip. The remaining species, *C. montanum*, comes nearer to its eastern relatives in its long brownish sepals and petals, but the lip is small and the flowers are peculiar in being very fragrant.

S. W.

Aquilegia longissima.

REFERRING to the illustration and description of this Columbine, p. 31, let me say a word about it as a garden plant: It "was found first by Dr. Palmer in August, 1880, in the Cara-

**C. FASCICULATUM*, Kell.; Watson. Proc. Am. Acad. xvii. 380. Low (from 3 inches to a foot in height), the stem villous-pubescent and bearing a pair of ovate or broadly elliptical leaves; flowers one to four, approximate, shorter than the bracts; sepals and petals greenish, lanceolate, acuminate, six to ten lines long, the lower sepals united; lip depressed-ovate, four or five lines long, greenish-yellow with a brown-purple margin.

col Mountains, 21 miles southeast of Monclova, in the State of Coahuila."

Dr. Palmer secured herbarium specimens and seeds for the Botanic Garden, Harvard College. The seeds were given to me, and from them in the spring of 1881 I raised a few good plants; some of these were distributed among our correspondents at home and in Europe. During the first year the plants were grown in a cold-frame. In the spring of 1882,

Fig. 16.—*Cypripedium fasciculatum*.

leaving two plants in the frame, I set out the others in the rockery. All of them bloomed the following summer, coming into bloom about the end of July and continuing in flower till the end of September. A few were sent to correspondents, the others were wintered where they had been growing all summer; those in the rockery, having, in common with the other plants, a light mulching of tree leaves and sedge. In the following spring (1883) they were all alive and as healthy and fresh as *A. chrysantha* or any other species, and grew and

flowered the next summer in about the same style as they did the previous year.

It is a desirable garden plant because it is the latest blooming of all the known species, coming in when *A. chrysantha*, the next latest, is still in good flower, and continuing in blossom long after that species has ceased to bloom. It is less robust and less profuse than *A. chrysantha*, and its flowers are of a paler yellow shade and less showy. But its long slender spurs have a weird appearance and hang about the flower branches like strings of yellow Dodder. The spurs on the cultivated plants were from 3 to 6 inches in length and averaged about 4½ inches; indeed, they gave the impression that it was on account of their weight that the flowers "looked up" so much. None of the cultivated plants were ever known to produce any seed.

Since coming here I have been very anxious to obtain a plant of this strange Columbine, and with this end in view have sent to Cambridge, and also to all the correspondents to whom I had sent plants, and in all cases have been informed that the plants have died. It is now entirely lost to cultivation. But although in its native habitats "the known localities are not readily accessible," I hope we shall soon again have the pleasure of seeing it in our gardens.

In June, 1886, Dr. Asa Gray told me he had, two years before, given plants of it to Mrs. Pickering, of Harvard College Observatory, and that they had grown and flowered remarkably well with her. Mrs. Pickering is an enthusiastic and most successful grower of garden flowers and has a very select collection. I at once wrote to her, and she replied that her plants had died the previous winter. In a subsequent letter she gives me more particulars: "I tried one plant in the cold-frame, and transplanted the other in spring and fall. The one in the frame died first. The other was left out one winter and disappeared. The transplanted one did well for two summers, giving eight or ten flowers later than the other Columbines. The roots were so very long it was difficult to transplant it, but it did not seem to suffer materially in consequence. I liked the plant. The flowers were very showy in individual vases. But it was not as beautiful as *A. chrysantha*, the next in size, and which is to me the most beautiful of all the Columbines. I was sorry to fail with this Columbine, as I have never failed with Columbines before."

I feel assured that the plant is not very hardy, and should we get it again, it must be wintered in a frame. But if a perennial supply of seed be not obtained I fear we cannot keep it long after we do get it, for Columbines are not long-lived perennials, and propagation by means of division will be uncertain.

Cultural Department.

Small Fruits for Home Use.

THE Strawberry that will prove equally good on all soils, and under all conditions, has not yet been produced, and probably never will be. The same is true of other fruits, which accounts for the conflicting opinions as to the merits of the various kinds. If earliness, profuse bearing and acidity are desirable, the wants of the grower would be supplied by Crescent, May King and Manchester. If he requires quality with earliness, Cumberland would be better. If quality is more important than earliness, Downing, Prince, Belmont or Bidwell would answer. If size and beauty are wanted, Jewell will furnish these, and a good quality as well, and so will Jersey Queen, with a higher degree of acidity and flavor. If extra size, and sweetness without high flavor, are more desirable than heavy cropping, they can be found in Sharpless or Davis; and so the list might be varied *ad infinitum*. Numbers of new varieties are constantly being produced and tested, but time is required to determine their relative merits for general planting. Those named are the leading kinds of established reputation, and from them all reasonable requirements for home use can be fully met.

It is not advisable for the inexperienced to confine his planting to one or two sorts, a half dozen would cover the season better, and if one or more should fail from want of congenial soil or other cause, the others would be more likely to supply the deficiency.

As the Strawberry supply draws to a close the Black Cap Raspberry begins, the Souhegan being among the earliest and best. Possibly the new Carman may prove a formidable competitor—it certainly will if it maintains the promise it made in its original home. The Gregg is the largest of the Black Caps so far tried, as well as the latest. It is less juicy and more

solid than the others named and the canes are not quite as hardy; otherwise Black Caps do not vary materially, and all are so seedy that they are often refused by persons of delicate organization, or perhaps disorganization is a better name for this weakness of digestion. The Shaffer is a dull purplish-red berry, of the Cap variety, of immense size, of fair quality and especially valuable for canning. It is the strongest grower of all and very productive. The Caroline, a salmon-yellow hybrid of the Cap and Antwerp, is a gem for family use. It is as early as Souhegan, and its delicate texture, fine flavor, immense productiveness and thorough hardiness make it a great favorite. The new Golden Queen may prove its equal, but it is difficult to imagine how it can be any better.

Of the red varieties the Early Prolific has always given me satisfaction for good size, earliness and productiveness; its quality is not of the best, but all earlier varieties are either too small, unproductive or inferior in quality. The Cuthbert is the most popular of the red varieties for home use; it is large, prolific and of good quality, of vigorous growth and suckers abundantly. The destruction of the superfluous plants in all of the red varieties is essential to the most satisfactory results. The Marlboro' and Montclair, though not so well known or widely disseminated, are quite as good for family use on soils adapted to their growth, being as large and sweeter in flavor. Here also adaptability to soil and freedom from disease must be considered. The various fungus-diseases attacking red Raspberries have not attracted the attention of mycologists to the extent they deserve, and we know little about them save their destructiveness.

Plants on rich soil and mulched in a dry time, are, I think, less liable to attacks of these fungi than those under opposite conditions. No two persons would agree on the same list of Raspberries, although the foregoing are the best of the most popular kinds for family use. The exacting amateur will demand the foreign sorts, which are not hardy in this climate without protection.

E. Williams.

Montclair, N. J.

The Kitchen Garden.

HERE, on Long Island, about the middle of April, we are sowing and planting all the hardy vegetables and preparing our ground for the tenderer crops. I endeavor to have all empty ground cleared, manured and dug in fall to lessen the spring work. Crops do better than in land freshly manured in spring. It is not necessary to fork over light or sandy land, that lies high and dry, in spring. The surface should be raked smooth with a wooden rake, and then lined off for sowing seed or setting out plants. But heavy land, or even light land that has lain under water during winter, should be forked over. Never put a plow, spade or fork into heavy land till it is dry and mellow. I begin working our high, sandy land about the end of March, and our deep, level garden soil about the second week in April; but we have a springy piece of ground, which, although thrown up in ridges over winter, is not fit for the spade till the end of May.

The kitchen gardens on private grounds are generally laid out and cut up into squares in such a fashion as to render the use of the plow in them impracticable; indeed, old-country gardeners, as a rule, have a prejudice against the plow in the kitchen garden. But no spade or fork can prepare and pulverize soil for crops as well as can the plow and harrow. True, by hand power we can crop our gardens closer than by horse power, but the saving in labor and time is immense. While it would be well to have a garden where Chives, Parsley, Radishes, herbs for seasoning, and such miscellaneous little things of which we need only a small quantity at a time, could be grown, we should try to have our heavy crops, as Corn, Potatoes, Cauliflower, Tomatoes, Beans, Peas and the like, in an open area, where we could use horse power.

And in preparing ground a common digging fork does far better work than the spade, and with less effort, and for leveling and smoothing ground a wooden toothed rake is better than an iron one.

It is only the vegetable garden, but try for an air of neatness about it. See that the beds are square and the drills straight. Do not use up open ground for Spinach, Lettuces, Radishes or other crops that can be slipped in between larger ones. Do not have a lot of unused ground at any time; put in something, if only Lettuces, Cabbages or Beans, to feed to the animals. After Spinach, Beans, Peas, Beets or anything else becomes too old for culinary purposes, clear them away at once. Do not put in more of a crop at a time than you will need; it is useless labor and expense. And especially look to this in spring; it is not a large quantity of any one thing we

should put in, but rather a small quantity repeated in successional sowings. This is true of Peas, Beans, Corn, Beets, Turnips, Spinach, Lettuces, Radishes and some others. But of Onions, Potatoes, Artichokes, Asparagus, Parsley and others that readily suggest themselves, we should now get in a full crop.

Transplanting.—Contrary to advice usually given, transplanting garden plants should always be done in clear, pleasant weather. It is a great mistake to select a rainy day for this important work. Plants should not be taken up, either for transplanting into the garden or for potting for the window garden, when the ground is wet. It is better to do this work when the soil is reasonably dry, so that it will drop entirely from the roots without injury to them. When the soil is wet and heavy much of it is sure to drop from the plant in

rain are in too great haste to get through, to do their work well.
C. L. A.

Begonia gracilis, var. Martiana.—Mr. Pringle's note (page 7) upon the native habitat of this favorite old green-house plant is highly interesting, for the information he gives of its being found so far north quite accounts for the fact that it can be grown here, in England, in cool houses, where the artificial heat is just enough to keep frost out. Not long since I saw a raised brick bed in an orchard-house, with no heating pipes, quite over-run with the scaly tubers of this beautiful plant, which in bloom in a large mass had a charming effect. Mr. Sereno Watson may be interested in knowing that it has by no means gone out of cultivation here, but that it is one of the most cherished of green-house Begonias. In the Royal Horticultural Society's garden at Chiswick, it was a few years ago

Fig. 17.—The Yellow wood.

taking up, and with the soil will go the delicate feeding roots, that will remain uninjured if the change is made when the soil is dry. Transplant in a clear, warm day, make a hole sufficiently large to hold the roots without crowding, fill with water, put in the plant, fill the hole with earth, which will immediately become soft mud, press this firmly around the plant, and cover the surface with perfectly dry, fine earth, and the plant will never flag or droop, no matter how sunny or warm the day may be. The writer has practiced this plan for years and has never lost a plant, not even the most delicate subject.

It may be urged that this is not practicable in large fields where Cabbage or Tomato plants are to be set. But the best way is always the most practical, and it is much cheaper to devote a day to putting out plants and have them all live and thrive, than to put them out in half the time and have a large portion die and the remainder linger along only half alive. It should be considered, too, that men who work out in the

grown to great perfection as a pot plant. Another variety of *B. gracilis*, named *diversifolia*, is also in cultivation at Kew and elsewhere.

Hardy Shrubs for Forcing.—To Mr. Falconer's list of shrubs (page 6), suitable for forcing into early flower, I should like to add a few, knowing that they are among the finest. The new *Prunus Pissardii*, or purple-leaved Plum, is the loveliest shrub imaginable when forced into early bloom, indeed it is naturally so precocious that it requires little or no artificial heat to bring out the flowers. Some bushes of it, four or five feet high, in the green-house at Kew, are mantled with white blossoms so profuse that the newly unfolded foliage is obscured. The flowers are about an inch across and have pink centres, while the new foliage, which at maturity is of a rich ruddy purple, is only slightly tinged with a vinous hue at flower time. This Plum may be lifted in autumn and potted for forcing, and taken into a slightly warmed green-house in February. Another first rate plant to force is Maule's Quince (*Pyrus*

Maulei), which has flowers like the common Japan Quince, but more orange in color—some call it orange red or orange scarlet. Small bushes of it, which are always very twiggy and spreading, have every shoot wreathed with bloom, which, in contrast to the pale green foliage, is admirable. This, too, requires very little forcing, but more than the purple-leaved Plum, because it naturally flowers later in the season. Waterer's Cherry (*Prunus Pseudo-Cerasus Watereri*) is matchless in its way when forced into bloom in March. The flowers are double and white, with just a suggestion of pink. A good plant of this in a conservatory or room lasts in bloom a long time, and in my opinion is very difficult to excel. *Forsythia suspensa*, and *F. Fortunei*, also force well, the plants hang like clouds of yellow bloom, if not unduly forced. The third week in March, onward, is not too early for them. W. G.

Consider the Lilies.—As soon as the weather will permit, and the ground becomes dry, examine Lilies planted in the fall, and where the frost has disturbed them make the soil firm by treading it down. All Lilies should be mulched in the fall, but if this was neglected it should be done at once. No better mulch can be used than equal parts of leaves and half-rotted chopped manure. It should be at least four inches deep. Such Lilies as *L. auratum*, *L. Wallacei*, *L. Leichtlini*, all forms of *L. speciosum*, and the species which flower after July, can be planted now with success, if it is done at once, and the bulbs are strong and plump. The top of the bulb should be three inches below the surface when the work is finished. Strong or green manure should not be used, rather plant with none; but if a compound of well-rotted manure and leaves can be had, use a spadeful for each bulb and mix it thoroughly with the soil. Plant firmly and mulch.

Peonies will be greatly benefited by a few forkfuls of manure placed around each plant. These gorgeous and easily cultivated flowers are fast growing in favor. Blooming as they do immediately after the first hint of summer weather, they should, in their season, hold as high a place in popular estimation as does the Chrysanthemum later in the year.

J. T.

The Yellow-wood.

OUR illustration on page 92 represents a specimen of the Yellow-wood which grows in a garden near Boston. This tree is about forty years planted, and is thirty-five feet high, with a spread of branches of nearly sixty feet. Botanists know the Yellow-wood as *Cladrastis tinctoria*. The generic name *Cladrastis* is of rather obscure derivation, but the specific name relates to the wood, which yields a clear yellow dye. Originally this tree was erroneously referred to the genus *Virgilia* as *V. lutea*, and by that name it is still best known, and more often spoken of by cultivators than as *Cladrastis*, the name *Virgilia* being now often used as an English word in speaking of this tree. The Yellow-wood is one of the rarest trees in the North American forests. It grows only in a few isolated localities from middle Kentucky and Tennessee to the extreme south-western portions of North Carolina; and is found on rich hill-sides and on steep rocky river-bluffs. It was discovered by the elder Michaux, the French botanist, during one of his last journeys into the territory west of the Alleghanies, and was introduced into Europe late in the last century. Few trees are more beautiful at all seasons of the year; and few adapt themselves more rapidly to varied conditions of soil and climate, or are more thoroughly satisfactory in cultivation. The trunk of the Yellow-wood often divides near the base, or throws out large low branches, and while this habit renders it particularly beautiful as a lawn or ornamental tree, as our illustration shows, it increases the danger of old specimens splitting in the fork or losing their branches. This often occurs owing to their brittleness; and this is the only drawback to this tree in cultivation which has yet appeared. It is very hardy as far north as New England and grows rapidly in all soils and situations; although, like other deciduous trees, it needs deep, rich soil to bring out its greatest beauties. No insects prey upon its dark green, graceful foliage; its beautiful, long, pendulous racemes of pure white fragrant flowers appear in June when most other trees have passed their blooming period; and the clear yellow tints of the autumn

foliage contrast pleasantly with the scarlets of Oaks and Maples. The Yellow-wood is a beautiful object in winter. The perfectly smooth, light-gray bark of its trunk and the delicacy of its branchlets recall the American Beech, which alone among our native trees excels it in these characters.

The wood of this tree has considerable value in addition to its value as a dye-wood, and if it could be obtained in sufficient quantities would find many uses. It is heavy and very hard, strong, close grained and susceptible of a good polish. Its color when first cut is bright, clear yellow, changing with exposure to light brown. At one time it was prized in Kentucky and Tennessee for gunstocks.

A second species of the genus *Cladrastis* is known (*C. Amurensis*), a small tree from Manchuria, with smooth brown bark and short spikes of small inconspicuous flowers. This tree is perfectly hardy in New England, where it flowers and ripens its fruit very freely. It is, however, inferior in every way to our American species as an ornamental tree, and is hardly worth cultivating except as a curiosity. C. S. S.

The Forest.

Influence of Undergrowth on the Increase of Timber.

WHILE we are talking of forestry as if it consisted simply in the planting of trees, or in preventing the lumberman from cutting wastefully, or in protecting the woods from fire, we are apt to overlook another much more positive and practicable object of forestry, which consists in making the most of our remaining natural growth, or in improving the young forest that nature provides after the virgin timber has been removed. In the Northwestern States especially there is a large area of second growth which is much inferior to what it might be, in kinds of timber, quality and fitness of crop. Here is where forestry should first be applied to fill out bare spots, to improve the crop, to make it grow more readily, to favor superior kinds, and so on. The whole theory of thinning should be carefully studied by holders of such forest property, for a dollar spent now in this direction may return manifold and earlier, than if nature is allowed to go on in her bungling ways.

While, theoretically, a tree with the full enjoyment of light would produce more leaves and therefore more wood than the one that is narrowed in by neighbors, on the other hand, the densely shaded soil offers more favorable conditions of growth than the open, bare or sodded ground. To balance these two factors of growth so as to produce an optimum is one object of forest management. The beneficial influence which undergrowth exerts upon the physical conditions of the forest soil, especially in preventing undue drying out by surface evaporation, is so well recognized, that the establishment of such undergrowth forms often an important part of forest management, for the beneficial influence upon the soil is naturally reflected in the prosperity of the principal growth.

The writer has seen a number of oaks some eighty years old which were left standing on a clearing to grow on for the next rotation, sickening and dying at the top. As soon as the young growth of hard wood underneath had covered up the foot of these oaks, they revived, recovered fully, and grew vigorously. Observance of these effects, of light on the crown and shade at the foot, has given rise to a management, by which, either a well grown forest is thinned out, leaving a certain number of trees to produce more quickly heavy sizes under the increased light influence and underplanting these for the purpose of preserving good soil conditions; or else, a naturally thin stand of trees may be so undergrown, in order to improve the production of the principal growth.

Such stands are not unfrequently found in Germany, where the villagers have tried to combine pasturage with tree-growth, mostly oak, by which the latter usually got the worst of it; the trees after a certain time showing no appreciable increase. The numerical result of this management may be seen from the following actual measurements.

In 1856 a stand of oaks then 130 years old, under which pasturage had been practiced, was thinned out and undergrown with beech, and last winter, thirty years after the operation, it was cut with the following results per acre:

a. Principal growth: 45 oaks, of 68 feet average height, yielding 3,320 cubic feet of solid wood, of which 2,082 cubic feet or 64 per cent. were over 6 inches in diameter, fit for

lumber or ties; the balance represents $13\frac{1}{2}$ cords of firewood, of which 45 per cent. was split wood. In addition 11 cords of inferior brush wood were utilized.

b. The undergrowth of course yielded only firewood, altogether at the rate of 14 cords per acre, of which only 20 per cent. was a better class of wood. The total yield of wood per acre was, therefore, 4,765 cubic feet.

Measurements of average trees were then made at the height of 1 meter, 3 meters, 5 meters and 6 meters with regard to accretion, and the average increase in the area of the transverse cut expressed in per cent. was found as follows:

During		During		
2nd	1st	1st	2nd	3rd
Decade Before Undergrowing.		Decade After Undergrowing.		
1.02	1.11	1.82	1.78	1.58

The mass accretion expressed in per cent. moved as follows:

0.98	1.00	1.82	1.44	1.53
------	------	------	------	------

Now as the total cross section area—that is, the sum of the cross section areas of the forty-five oaks upon an acre—was found to be in the average 380 square feet, the absolute increase of this area in square feet during each decade was as follows:

3.88	4.22	6.92	6.76	6.00
------	------	------	------	------

Similarly of the 3,320 cubic feet of wood found at the time of cutting, the following masses in cubic feet are to be credited to each decade:

32.54	33.20	60.42	47.81	50.8
-------	-------	-------	-------	------

That is to say, as a consequence of the undergrowing there was visible a decided increase of wood production—2.70 square feet in cross section area and 27.22 cubic feet in mass; but this increased production was kept up during thirty years, so that the third decade furnished still 1.78 square feet and 17.6 cubic feet more than the decade before the undergrowing.

B. E. Fernow.

Professor H. M. Ward gives in *Nature* the following account of an experiment conducted by Professor Hartig:

"There is a plantation of Larches at Freising, near Munich, with young Beeches growing under the shade of the Larches. The latter are seventy years old, and are excellent trees in every way. About twenty years ago these Larches were deteriorating seriously, and were subsequently underplanted with Beech as foresters say—*i. e.*, Beech plants were introduced under the shade of the Larches. The recovery of the latter is remarkable, and dates from the period when the under-planting was made.

"The explanation is based on the observation that the fallen beech-leaves keep the soil covered, and protect it from being warmed too early in the spring by the heat of the sun's rays. This delays the spring growth of the Larches: their cambium is not awakened into renewed activity until three weeks or a month later than was previously the case, and hence they are not severely tried by the spring frosts, and the cambium is vigorously and continuously active from the first.

"But this is not all. The timber is much improved: the annual rings contain a smaller proportion of soft, light spring wood, and more of the desirable summer and autumn wood consisting of closely-packed, thick-walled elements. The explanation of this is that the spring growth is delayed until the weather and soil are warmer, and the young leaves in full activity; whence the cambium is better nourished from the first, and forms better tracheides throughout its whole active period."

Correspondence.

To the Editor of GARDEN AND FOREST,

Sir: I send you a short list of books and papers which influenced, or recorded, the beginnings of the modern art of landscape gardening.

The list is headed by Bacon's familiar Essay, in which some directions for the making of a wild garden are given; but long before Bacon there were plain signs of the coming of the day of naturalistic gardening. The poetry of Dante (1321) is full of sympathetic feeling for the beauty of the natural world—for meadows, woods, streams and flowers, even for the sea and the distant mountains. Petrarch, Boccaccio, Ariosto and Tasso betray no such fresh feeling for Nature as does their great predecessor. Yet in Tasso's "Jerusalem Delivered" (1595) is the following remarkable description of a garden scene:

"Everything that could be desired in gardens was presented to their eyes in one landscape, and yet without contradiction or confusion—flowers, fruits, water, sunny hills,

descending woods, retreats into corners and grottoes—and what put the last loveliness upon the scene was that the art which did it was nowhere discernible. You might have supposed (so exquisitely was the wild and the cultivated united) that all had somehow happened, not been contrived. It seemed to be the art of Nature herself, as though in a fit of playfulness she had imitated her imitator."—(Leigh Hunt's translation.)

But it was in England that the love of Nature took firmest root. Chaucer (1400) and Spenser (1599) sang of the things of nature with a very fresh delight; and Milton, in the fourth book of "Paradise Lost," imagined a garden which was an Eden indeed.

England also raised up Shakespeare, whose love embraced the

"daffodils
That come before the swallow dares, and take
The winds of March with beauty;"

and Cowley, whose delight was that characteristic one for an Englishman, "a small house and a large garden"; and, later, Thomson, Cowper, Gray, and Wordsworth.

Meanwhile the art of landscape painting had been growing up. Titian, its founder, composed the first landscapes upon canvas in the days when Tasso was imagining the garden of Armida; Claude Lorraine, Salvator Rosa and Poussin were contemporaries of John Milton.

Well might Wordsworth write (1805) to Sir George Beaumont: "Painters and poets have had the credit of being reckoned the fathers of English gardening"; and he adds, "they will also have, hereafter, the better praise of being fathers of a better taste."

"Bacon was the prophet, Milton the herald, of modern gardening; and Addison, Pope and Kent the champions of true taste"—thus the Rev. William Mason in 1772, when the sort of landscape-beauty long imagined by the poets was beginning to be realized in the English parks. Addison and Pope, each, in his few acres, practiced what he preached—Addison at Bilton near Rugby, Pope at Twickenham near London. Bridgeman, a professional gardener of the period, is said to have been converted by Pope's paper in the *Guardian*, and thenceforth to have abandoned the clipping of trees; while Kent, a painter, gave up his art to become the first landscape gardener.

The first complete treatise on the new art was Whateley's still indispensable "Observations," published in 1770, and immediately translated into French and German. A few years later appeared Girardin's excellent French work, and Hirschfeld's six volumes printed in German and French. Later came Gilpin's delightful accounts of his English tours, which had great influence in waking the popular interest in natural scenery, and Knight's and Price's vigorous attacks on the smooth monotony which characterized the landscape work of Brown and his imitators.

Shenstone, Whateley, Girardin, Walpole, Knight, Price and Laborde, all worked out their ideas on their own estates; and it is interesting to know that Rousseau, the contemporary of Gray, who yet was the first modern Continental author to write feelingly of natural scenery, was a frequent guest of Girardin's at his Ermenonville.

To close the list we have the writings of a few of the first landscape gardeners themselves—Repton and Loudon for England, Viart and Thouin for France, Sckell and Pückler-Muskau for Germany.

Mr. Editor, I hope to see printed in GARDEN AND FOREST numerous extracts chosen from these books. I am sure you can do us Americans no better service than thus to advance "the better praise" of the founders of the art and their principles. I am, sir, yours respectfully,

Boston, 1st March, 1888.

Charles Eliot.

A List of Books on Landscape Gardening.

1625. FRANCIS BACON, Lord Verulam.—"On Gardens," one of his "Essayes or Counsels Civill and Morall."
1712. JOSEPH ADDISON, essayist, Secretary of State.—"On the Causes of the Pleasures of the Imagination arising from the works of Nature, and their superiority over those of Art." In *The Spectator*, No. 414.—"A Description of a Garden in the Natural Style." In *The Spectator*, No. 477.
1713. ALEXANDER POPE, poet and essayist.—"On Verdant Sculpture." In *The Guardian*, No. 173.
1731. ———.—"An Epistle to the Right Honourable Richard, Earl of Burlington." London, fol.
1764. WILLIAM SHENSTONE, poet and essayist.—"Unconnected Thoughts on Gardening." In his collected works. London, 8vo.

1768. GEORGE MASON, "a classical scholar and critic."—"An Essay on Design in Gardening." London, 8vo.—An enlarged edition, 1795. London, 8vo.
1770. THOMAS WHATELY, Secretary to the Earl of Suffolk.—"Observations on Modern Gardening, illustrated by Descriptions." London, 8vo.
1772. Rev. WILLIAM MASON, poet, Canon of York.—"The English Garden: A Poem in four books." London, 4to.—A new edition, 1785. London, 8vo.
1773. CH. CAL. L. HIRSCHFELD, "counselor to his Danish Majesty, Professor of the Fine Arts at Kiel."—"Ammerkungen über Landhäuser und Gartenkunst." Leipsig, 12mo.
1774. CLAUDE HENRI WATELET, Receiver-General of Finance, Member of the Academy of Sciences.—"Essai sur les Jardins." Paris: 8vo.
1774. SIR WILLIAM CHAMBERS, F.R.S., architect.—"Dissertations on Oriental Gardening." London, 4to.
1776. J. M. MOREL, architecte.—"Théorie des Jardins, ou l'Art des Jardins de la Nature." Paris.
1777. L. R. GIRARDIN, Vicomte d'Ermenonville.—"La Composition des Paysages sur le terrain, etc." Geneva: 8vo.
1777. CH. CAL. L. HIRSCHFELD.—"Theorie der Gartenkunst." Leipsig: 6 vols., 4to.
1780. HORACE WALPOLE, Earl of Orford.—"On Modern Gardening." In his "Anecdotes of Painting."
1783. DANIEL MALTHEUS.—An Introduction to a Translation of Girardin's "Essay on Landscape." London, 8vo.
- 1783-1809. Rev. WILLIAM GILPIN, M.A.—"Observations relative chiefly to Picturesque Beauty" in many parts of Great Britain. London, 8 vols., 8vo.
1785. WILLIAM MARSHALL, estate agent.—"Planting and Rural Ornament." London, 8vo.—A second edition in 2 vols., 1796. London, 8vo.
1791. Rev. WILLIAM GILPIN.—"Remarks on Forest Scenery, etc." London, 2 vols., 8vo.
1792. ———.—"Three Essays: On Picturesque Beauty, On Picturesque Travel, On Sketching Landscape, etc." London, 8vo.
1794. RICHARD PAYNE KNIGHT, "a gentleman of great classical attainments."—"The Landscape: A didactic poem." London, 4to.
1794. SIR UVEDALE PRICE, "a gentleman and scholar of great taste, who has greatly improved and beautified his own estate."—"An Essay on the Picturesque, etc." London, 8vo.
1794. HUMPHREY REPTON, landscape gardener.—"Letter to Uvedale Price, Esq., on Landscape Gardening." London, 4to.
1795. ———.—"Sketches and Hints on Landscape Gardening, etc." London, fol.
1803. ———.—"Observations on the Theory and Practice of Landscape Gardening, etc." London, 4to.
1803. JOHN CLAUDIUS LOUDON, landscape gardener.—"Observations on laying out the Public Squares of London." In *The Literary Journal*.
1804. ———.—"Observations on the Theory and Practice of Landscape Gardening, etc." Edinburgh: 8vo.
1806. ———.—"A Treatise on forming, improving and managing Country Residences." London, 2 vols., 4to.
1808. ALEXANDRE LOUIS JOSEPH, Comte de Laborde.—"Descriptions des Nouveaux Jardins de la France." Paris: folio.
1812. JOHN CLAUDIUS LOUDON.—"Hints on the Formation of Gardens and Pleasure Grounds." London, 4to.
1818. F. L. VON SCKELL, landschafts-gärtner.—"Beitrag sur bildenden Gartenkunst." Munich: 8vo.
1819. GABRIEL THOUIN, architecte-paysagiste.—"Plans raisonnés de toutes les Espèces de Jardins." Paris: folio.
1819. ———.—VIART, architecte-paysagiste.—"Le Jardiniste Moderne, etc." Paris: 12mo.
1822. JOHN CLAUDIUS LOUDON.—"An Encyclopædia of Gardening, etc." London, 8vo.
1832. WM. S. GILPIN.—"Practical hints on Landscape Gardening."
1834. FÜRST HERMANN LUDWIG HEINRICH VON PÜCKLER-MUSKAU.—"Andeutungen über Landschafts-gärtneri." Stuttgart: folio.

Periodical Literature.

THE first Lime Tree on the great avenue called *Unter den Linden*, in Berlin, was planted in 1680, the first house having been built three years before. The story of this first planting and of those which have since been made is told by Herr Rodenberg in the *Deutsche Rundschau* for November, 1887; and in subsequent numbers of the magazine he has outlined the history of the famous street which has witnessed so many striking political and social scenes.

The title of an article by Lord Fortescue in the March number of the *Nineteenth Century* will doubtless attract the eye of many who are interested in the development of a love for flowers among the poor. But upon examination "Poor Men's Gardens" proves to be simply a treatise upon the question, much discussed of late in England, of the advisability of letting to members of the laboring classes "allotments" of ground at a distance from their homes, by the cultivation of which they may add to the food supply of their families.

The great and ancient Forest of Fontainebleau has been made famous all over the world by the genius of the band of landscape painters who, in the last generation, devoted their lives to depicting its venerable Oaks, its heathly glades, its melancholy pools and its huge groups of moss-grown rocks. All who know and admire the pictures of Rousseau, and Diaz and Dupré, and of a host of later comers who have followed in their traces—and the number must be legion in America—will be interested to read an account of the Forest of Fontainebleau written by Mr. J. Penderel-Brodhurst and published in recent numbers of the *Magazine of Art*. And even to those whom no artistic magnet has attracted to this forest, these articles will be attractive; for by describing the scenes of humble life which, winter and summer, are busily enacted beneath the Oaks of Fontainebleau, the difference between what is meant in Europe by a forest and what is meant by one in America, is vividly set forth.

In *Chambers' Journal* for February will be found a brightly written, yet instructive article called "Early Blossoms." The chief flowers of which the author speaks are Snowdrops and Crocuses, giving us at some length the history of their introduction into European gardens, speaking especially of the species of Crocus which furnishes the saffron of commerce, and describing the singular vicissitudes of public favor and disfavor which this substance has undergone.

The *Popular Science Monthly* for April contains an attractive and instructive chapter on "Californian Dry Winter Flowers," by Professor Byron D. Halsted. It gives an account of observations made in the vicinities of Los Angeles and Santa Barbara in the winter of 1886-'87, when the rainy season was unusually late, and the plants which were in bloom had received no rain for nearly ten months. In view of this fact, it is surprising to read the long list of such plants—plants "which grow without irrigation, and blossom from the dust"—and to note how many of them belong to genera whose eastern representatives flourish only under very different conditions. Excluding the garden flowers of which, if he will but supply a little water, the Californian may have "the whole list in mid-winter," Professor Halsted pronounces the most attractive flowers he found to be those of the phlox-like *Gilia Californica*. "This shrub is two or three feet high, and grows upon dry hill-sides. The leaves are thickly set and villous, while the stems are terminated by clusters of rose or lilac-colored flowers an inch or more across the limb. The fragrance is indescribably rich when not too profuse." This plant is locally called the "Mountain Pink," and next to it in attractiveness, the author ranks the *Hosackia glabra*, of the order Leguminosæ, a shrub with long decumbent stems and yellow and brown flowers.

The most interesting article for lovers of nature in the recently completed eighty-third volume of the *Revue des Deux Mondes* is Monsieur Th. Bentzon's "Le Naturalisme aux Etats-Unis," the exact bearing of which is more clearly defined by the sub-title "La Bibliothèque du Plein Air." Monsieur Bentzon—who, by the way, is a lady, writing under an assumed name, with a special predilection for American literature—reviews in this article, at considerable length and with high praise, the volumes contained in Messrs. Houghton, Mifflin & Co.'s "Out-door Library"—the works of Thoreau and John Burroughs, Lowell's "My Garden Acquaintance," and Miss Jewett's "White Heron," and speaks incidentally of the Journals of Agassiz and his wife, and of poems and stories by many other hands. The genesis of this out-door literature is traced, no doubt with much reason, largely to the combined influence of Agassiz's teachings and of Emerson's "Nature," and its development is looked upon as the effect, less of the wish for scientific knowledge than of the desire, on the one hand, to give literary outlet to the "animal spirits" of a young and vigorous race, and, on the other, of the Emersonian wish to trace the relationship between the soul of man and the soul of nature. We ourselves hardly realize, perhaps, how strongly the love for nature is expressing itself in our current literature. It is doubly pleasant, therefore, to find the fact recognized

abroad, where the American people is too often believed to be wholly given over to money-making industries, and as entirely devoid of the contemplative as of the poetic gift. There is one author, however, whom one regrets to find missing from M. Bentzon's list—Miss Murfree (Charles Egbert Craddock), whose pictures of nature in the mountains of the south-west deserve to be ranked with our best out-door poems in prose.

An article on "An Old-Fashioned Garden" by Mrs. A. M. Crompton in *Harper's Young People* for March 27th, is of just the sort which should frequently be written for youthful readers. Not often will any one be able to realize just "The garden of my dreams" as this author describes it—for it is described as one "which must be at least a hundred years old," and in which, though successive owners may have worked many alterations, at least "the trees and turf must have the beauty of age." But a garden where beauty means growing things in natural development and not an assemblage of statues and fountains and stiff showy pattern beds, where "old-fashioned" sweet-scented flowers bloom in abundance and birds delight to gather, where vines and creeping plants are trained with "an art that conceals art," where fruit-trees, shade-trees, shrubs and annuals all have their place and purpose, and where winter may seem almost as beautiful as summer—such a garden as this very many more people might have than is to-day the case. And it is difficult to believe that a strong desire for it will not be inspired by this charming little article.

Notes.

Plants bearing exclusively what purport to be four-leaved Clovers—or, as the Germans call them, "luck Clovers"—are sold just now in pots in the flower markets of Germany. They are said, however, not to be true Clovers (*Trifolium*), but certain species of *Oxalis*, which regularly produce leaves with four leaflets—*O. oculenta*, *O. Deppei*, or *O. tetraphylla*.

Herr Max Leichtlin has commissioned Paul Tintenis to travel for him in Armenia in order to collect bulbs and seeds for cultivation in the famous Leichtlin gardens at Baden. An herbarium will also be collected, illustrative of the Flora of Armenia.

A great Fruit Exhibition will be held in Vienna during the coming autumn, with the object not only of displaying the pomological products of Austria, but of increasing, among cultivators and the public, a knowledge of the newest methods of cultivating, preserving and utilizing fruits.

The Royal Society of Agriculture and Botany will hold its twelfth annual international exhibition during the latter part of this month.

A Horticultural Congress will be held in Paris in May, in conjunction with the annual flower show of the National Horticultural Society.

The fiftieth anniversary of the founding of the Horticultural Society "Hortensia" will be celebrated in Munich in July.

The Philadelphia Flower Show.

THE Spring Exhibition at Philadelphia last week fully sustained, in the quality of the collection, the high reputation won by the Pennsylvania Horticultural Society during its long and successful career. The number of plants and flowers displayed was smaller than usual, but this relieved the managers from any temptation to crowd them, and the arrangement throughout was admirable. The centre piece, with a cone of *Asparagus tenuissimus* rising from a bank of rich flowers and foliage to the high ceiling, was tastefully conceived, and no single feature of it was more pleasing than the immense Fuchsia, six feet high, with its wealth of bloom. It was a general remark that exhibitors could in no way do more to render flower shows attractive than by displaying finely-developed specimens of plants that are well known and "common." For some reason Orchids have not been cultivated as largely in the neighborhood of Philadelphia as they have been in other parts of the country. The fine display of these plants was therefore a surprise. The group of fifty plants from the collection of Mr. W. S. Kimball, of Rochester, New York, was especially noteworthy, every plant being well grown and in fine flower. Good collections were also shown by Siebrecht & Wadley, of New York, and Charles Dissel, of Philadelphia. Of course the spring flowering bulbs were abundantly displayed, and the hall was bright with Rhododendrons and Azaleas. But Roses, next to the Orchids, attracted the most attention. The flowers of Mrs. John Laing were unusually fine, and this variety did not suffer by comparison with Madame

Gabriel Luizet as they were seen together. No better Brides were ever exhibited, and Niphetos was almost as good. A cluster of General Jacqueminots from Boston were admired for their unusual size and the luxuriance of their foliage. Besides the old favorites, a prize was awarded to a Tea Rose called, provisionally, The Gem. No one was able to tell whether it was an old variety, revived by chance, or a sport. But its size, form and solidity give it great value. It is not a pure white, but has a pleasing suggestion of the faintest cream color, and the growers present agreed that it was a Rose of the greatest promise.

Retail Flower Markets.

NEW YORK, April 13th.

The stock of cut flowers is very heavy; so heavy indeed that only the choicest blossoms bring anything like a satisfactory price. Trade is good on the chief thoroughfares, but is generally dull on East-side avenues. A few large weddings have brought orders for handsome designs for gifts, but the average demand is for flowers not selected. Paul Neyron and Baroness Rothschild Roses are particularly handsome. They bring 75 cts. each. Other hybrids of good quality cost 50 cts. Some very large La France Roses bring 60 cts. each. Catherine Mermets are poor, and Brides are showing considerable color on the outer petals. There is a glut of Callas and Harris's Lilies; the former are offered for 15 and 20 cts., and the latter for 25 and 30 cts. Lilac from New Jersey is very well grown and holds its price at 50 cts. a spray. Poet's Narcissus is scarce, and costs 50 cts. a dozen. Hyacinths, Tulips and Lilies-of-the-Valley cost from 60 to 75 cts. a dozen, according to quality. Very choice Lilies-of-the-Valley selected for bridal bunches, are sold for \$1 a dozen. Daffodils cost from 60 to 75 cts. a dozen. White Carnations are scarce, but those of other colors are plentiful and 50 cts. a dozen. Short-stemmed Carnations are sold for 30 cts. a dozen. Small Mignonette costs 25 cts. a dozen spikes. The large Spiral brings 10 cts., and the Giant holds at 15 cts. a spike. Forget-me-not of excellent quality appears, and costs 50 cts. a dozen sprays. Some Heliotrope of great beauty is in market, bringing 25 cts. a bunch. Other flowers, if of good quality, remain as last quoted. There is no price set upon the indifferent stock which gluts the market. It may be bought for any sum offered.

PHILADELPHIA, April 13th.

Roses are quite plentiful now, and the Hybrids are generally very fine. Magna Charta and Baroness Rothschilds are selling freely at from \$4 to \$6 per dozen. Mrs. John Laing is improving very much in quality, as also is Puritan and American Beauty. Amongst the Tea varieties, Madame Cuisin was in remarkable demand this week; one of the leading florists had difficulty in getting sufficient stock to fill his orders. It is a beautiful Rose, and not the least of its good qualities is the length of time it keeps in good condition. With brighter sunshine it becomes higher in color. Lilacs are still scarce, and much called for; very little is forced for cut blooms in the vicinity of this city. The beautiful single Daffodil is becoming more abundant, many coming from the warmer counties of New Jersey and Delaware. Some varieties of Carnations are improving in quality, notably Grace Wilder, a great favorite here. The delicate pink coloring is more decided than it is in the dark days of winter. It sells readily at from 50 cts. to 75 cts. per dozen. Buttercup is also very good, and in demand, selling at from 35 cts. to 50 cts. per dozen. Wedding breakfasts are growing in favor. Flowers are used on such occasions in great abundance.

BOSTON, April 13th.

On Monday last one of the leading dry goods firms created a sensation in the flower market by buying up all the Violets that could be obtained for that day and presenting them to their customers. The stock of Violets lasted only till noon, however, and the merchants were then obliged to fall back on Roses as a substitute, and the market was completely cleaned for once. A general adoption of this plan would not be unacceptable to the flower growers and flower dealers at present, for there is an overstock of flowers in almost every variety. Roses are particularly abundant yet, in spite of the low prices. Specially fine specimens of any popular variety still command customers at high figures. Some remarkable Jacqueminots bring \$4 to \$5 per dozen, and at the same time those of ordinary quality can be bought as low as \$1.50 per dozen, and a still lower grade is eagerly bought from the street boys at "three for a quarter." Catherine Mermets, Perles, Bennetts and Brides are all of first quality, and well worth the low price—about \$1.50 per dozen—asked for them. There is an abundance of Lilies-of-the-Valley, Tulips and Poet's Narcissus at \$1 per dozen. The yellow varieties of Narcissus are about gone for this season. Violets are 50 cts. per bunch and long-stemmed Carnations 50 cts. per dozen. White Lilies are still abundant in the market and they are used largely in the making up of funeral designs. Heath has disappeared completely, and but few Orchids are seen. Smilax continues very scarce and brings 50 cts. per yard readily. Some superb Hydrangea plants are to be seen in the florists' windows. These, with Canary Broom, "Longiflorum" Lilies and Cinerarias, are very popular as window plants this season. The Amaryllis is also growing in favor, and deservedly so, for it is easily grown and makes a striking display.

The Forests on the National Domain.

THE forest-covered public domain of the United States is now, with some exceptions in the Gulf States, confined to those portions of the country west of the 100th meridian. These forests, where they come within the direct and immediate influence of the Pacific Ocean, are unsurpassed in the quantity and value of the material which they contain; in all other parts of Western America insufficient moisture has made them thin and stunted. Such as they are, however, the forests of the interior regions of the continent play an important and controlling part in the development of all that vast region, and influence the welfare of communities which now perhaps never give a thought to their existence. For, although often scattered, thin and stunted, they regulate the great rivers of the continent and so have an important bearing on the material welfare of a very considerable part of the American people. China within the last year has shown us only too plainly what a great river, deprived of the protecting influence of the forest at its source, can accomplish in death and desolation; and what has happened in China, will some day happen in America, if the forests which now guard the mountain slopes above the head-waters of the Columbia and the Missouri are sacrificed through the greed or the indifference of our people.

A large population is directly dependent, too, upon these western forests, for the water they store for irrigation, without which no agriculture is possible in nearly all that region, and for the lumber and fire-wood they yield.

They are forests, too, such is the want of moisture in all the interior of the continent, which have a hard struggle for existence; the resinous character of the trees and the dryness of the soil make fires exceptionally dangerous and destructive; and these conditions render the restoration of a forest once destroyed practically an impossibility. We mention these familiar facts to show the necessity of applying

to these forests the most careful methods of protection and administration which can be devised, both because they are in themselves of very great value, and because peculiar climatic and topographical conditions make it a much more difficult matter to protect and extend them than those in more favored parts of the country. They can never be secure in private hands; they may be preserved and even extended if the general government can be made to realize, what all other civilized nations now realize, that forests are essential to the public welfare, and that they can be safely managed for the good of all only by government administration. Individuals are not, and never can be, safe guardians of a forest upon which a community depends; and perhaps the most important question which at this time waits the action of Congress is such a settlement of the future of the public forests as will prevent individuals from securing title to any portion of them, or from unlawfully entering or devastating them. Other public questions can wait a few weeks or a few months without any very serious or at least fatal results, but when a forest of Fir or of Redwood on the Pacific Coast is swept away, there is destroyed what it will require five centuries to restore; and twice that time will not be enough to cover with trees again the slopes of Colorado or Nevada mountains devastated by fire. And yet while Congress year after year refuses to consider seriously the question of forest protection on the public domain, thousands of acres of these forests are destroyed every year by fires which might have been prevented, or by trespassers who might have been caught and punished.

Two bills relating to the public forests now await the action of Congress. House bill No. 7901 has already been favorably reported upon by the Committee on Public Lands. The provisions of this bill contain many dangerous elements, and cannot effect the protection of the forests. It provides that the fee of certain lands shall remain vested in the Government, but that the timber may be sold from these lands without restriction, and it provides no administrative machinery for the protection of the forests from fire, always their greatest danger. The use of the military, except perhaps at the very outset, and before proper officers can be trained as forest guardians for such regions as it may be deemed expedient to retain in forest, is hardly a practicable measure, or one which is likely to result in any practical good. The public interest demands that this bill should be defeated.

House bill No. 6045 was prepared under the auspices of the American Forestry Congress, and has the endorsement of many persons most actively and intelligently interested in preserving the forests of this country. It provides that permanent forest preserves shall be established under a forest officer and proper subordinates. They are to embrace lands better suited for forest growth than for any other purpose, especially lands situated at the head-waters of important streams; and they are to be kept in permanent forest and to be carefully guarded from spoliation and destruction. Timber, however, may be sold when it is clearly advantageous to do so, but only under the direction of a government officer, and with a proper regard to the future development of the forest. Unauthorized cutting, and other injury to the preserved forests are to be made criminally punishable. Forest guardians, and methods for their appointment, are provided for, and the not excessive appropriation of half a million dollars to carry out the provisions of the bill is asked for. This bill has much to commend it, and it would be fortunate for the American people if their feeling and intelligence were sufficiently aroused upon this subject to compel politicians to stop and consider a measure of such vital national importance in the year of a Presidential election. In this bill, however, no provision is made for the proper training and education of forest officers, and yet forest administration, however wisely the laws upon which it rests may have been drawn, must depend for ultimate success upon the intelligence and enthusiasm of the officers who direct it.

Mr. John Robinson, as has already been explained in an earlier issue of this paper, has very wisely suggested that we must first have a forest school in this country modeled on the plan of the Military Academy, before we can hope to have forest officers thoroughly trained in all the difficult technicalities of forest management, or an efficient forest administration. The men will appear, no doubt, to manage the forests, when the Government decides to protect them, and they will manage them badly at first, and then in time very well, but no general forest policy is complete or adequate to accomplish the ends in view without some provisions for training forest officers, any more than a law to establish a standing army could be complete without provisions for training its officers.

It is true that many investigations are yet to be made upon the position, the extent and the character of our western forests before enough is known about them to locate properly forest reserves, or to organize an effective system of forest administration; but some beginning must be made. If this measure fails it might be well if all friends of the forest would unite in an effort to secure from Congress the withdrawal of the whole forest-covered public domain from sale and entry, with adequate temporary measures for its strict protection, and the appointment of some competent body, selected for example from the National Academy of Sciences, to study the whole question in all its complex bearings and to recommend some comprehensive scheme of forest administration. There could be no opposition to such a bill except on the part of those who prey on the public forests. Such a measure might diminish at once many of the dangers which now threaten to exterminate the western forests, and it would cause the subject to be studied and discussed in a manner which would compel Congress eventually to establish a permanent forest administration in this country. But whatever method is adopted one thing is clear, that unless Congress does something and does it quickly, there will be very little forest left in western North America, and the future of all that part of the Continent will be irretrievably ruined.

Flowers in Winter.

THE skill of American gardeners in growing flowers for winter cutting, and the lavishness of the American public in buying them, strike every visitor to our large towns. In no other country are flowers—especially Roses—forced in such perfection or profusion, and in none are they used in such quantities, not only on all social occasions, but for the daily adornment of the drawing-room and dining-room.

It is hard to say whether our passion for cut flowers reveals a love for nature or simply a love for beauty in general. But it certainly is not, as some would have us believe, a mere fashionable craze, with no more respectable foundation than extravagance and the desire for display. Fashion's freaks do not last for generations, and grow stronger and stronger in their influence year by year. But our love for cut flowers in winter has thus lasted and grown. A few years ago fashion certainly played a large part in determining the uses to which we put such flowers. No lady was content to appear in a place of public amusement without an immense bunch of flowers in her belt, and few were content to take their afternoon stroll unless similarly adorned. The request that no flowers may be sent which even now often follows a funeral announcement in the papers—though not so often now as a few years since—is an unmistakable sign that a custom which, when not carried to excess, is among the most beautiful and touching of modern times, had been carried to excess—had become a fashion that was felt as a tax upon the friendship of the giver and a burden upon the conscience of the recipient. And so strong for a while was the feeling that a lady could not go to an opera or a ball without bearing costly tokens of the regard of her friends, that

young men of moderate means were almost driven out of social life and the florist's bill came to rival the tailor's as a synonym for one of the worst terrors of city existence.

But all these things have changed of late; and in the change we may read signs of our growth in a real love for flowers, as well as in good taste and refinement of feeling. For the florist's trade has certainly not suffered in consequence of the fact that we use flowers less for the purposes of a display than in years gone by. If we do not buy so many flowers to give away in a semi-obligatory manner, we buy more for ourselves; and if we do not carry them about so much in public, we care more to have them with us in our rooms. Many of us can remember when a lady often placed her baskets of flowers in her front window, between the curtains and the glass—sacrificing her own enjoyment so that every one else might know of her good fortune. Such vulgarities no longer offend the sight, but behind the curtains there are more flowers and lovelier ones than there ever were before.

The increase in the variety of flowers which we now force for winter use, and the simple character of many of them, also prove our advance in the right direction. Thirty years ago the Camellia ruled almost alone in our drawing-rooms. Then Roses began to come into favor, but they were as inferior to those of to-day in quality as they were in variety. It is scarcely twenty years since the most beautiful and fragrant of the other flowers we now demand were introduced into the winter trade—the Hyacinths and Lilies-of-the-Valley, the Daffodils and Narcissus and Tulips, which may now be bought any day in the winter for a few pence at any street corner, bringing into humble homes the loveliness which in former years was a luxury for the rich alone. The first bouquet of Lilies-of-the-Valley which was seen in a New York ball-room—some twenty years ago—was the talk of the town for days, and the florist who had grown the few sprays which composed it, and the young man who had bespoken them long in advance of their blooming, were looked upon as marvels of inventiveness and enterprise. These blossoms and their fellows had before that time been considered "common garden flowers," unworthy of a place in a florist's window or a lady's hand when winter made their acquisition difficult. But one experience of their charm among the time-honored favorites of the drawing-room, gained a place for them in popular affection, which has enlarged itself year by year. More recently other "common garden flowers" have likewise come to rank as winter favorites—Lilacs, for example, and the Mignonette, Forget-me-nots and Chrysanthemums; and we believe that even the growing fancy for Orchids—a fancy inspired as often by the fact that they are rare and singular, as by the fact that they are beautiful—will not drive into even temporary retreat the simpler, cheaper flowers, which prove that our love for natural beauty is a healthy and a steadily developing sentiment.

A Plantation for Winter.

THE value of some deciduous shrubs with regard to their winter beauty is hardly appreciated. We think much of the flowers and foliage of our shrubs, little of the brightness and persistency of their fruit, or of the color which their twigs retain when their leaves have fallen. Yet the number of such plants which are decorative throughout the whole or a part of the winter is considerable. The finest and most beautiful is the Cockspur Thorn, a small and graceful tree which can be used as the centre of a winter group. Its large dark-red fruit is borne in great profusion, and remains conspicuous in the winter landscape until the days of early spring. Among smaller plants the common Barberry is the most valuable for winter planting. Its habit is graceful and its drooping racemes of fruit are brilliant objects throughout the entire winter. Less pleasing in habit but with fruit equally persistent and even brighter in color is Thunberg's Japanese Barberry.

The common Privet, one of the hardiest and most easily cultivated of plants, carries in this climate its bright black fruit well into April. Several of our native Roses also retain their showy red haws until spring, especially the tall-growing Carolina Rose, and, among dwarfed species, *Rosa humilis*, *R. blanda* and *R. nitida*. The conspicuous fruit of our native Bitter-sweet—orange-colored and red—remains upon the plant all through the winter season, and its free habit of growth will add a welcome touch of variety to the group of shrubs among which it may be planted. The Japanese Rhodotypus is another winter fruit-plant, although its greatest beauty consists in its pure white flowers and neat foliage. And to this list of shrubs which do not lose their fruit until the days when fresh foliage is ready to replace them, may be added many others which retain theirs for at least a portion of the winter. The different Spindle-trees are striking objects in late autumn and early winter; but although their brilliant crimson fruit is persistent through winter, it becomes dull and inconspicuous by the end of the year. Few plants are more beautiful in autumn than the Highbush Cranberry (*Viburnum Opulus*) with its load of orange-scarlet fruit, but the birds devour this so greedily that little is left at Christmas-time. Every one knows the beauty of the Black Alder as it blazes through our northern swamps during the autumn months, and although a native of swamps it grows freely in any garden soil. If planted for the sake of its fruit care should be taken to secure plants of both sexes. Its scarlet fruit generally disappears by Christmas, but in his account, recently printed in these columns, of the effects of the great spring storm in New Jersey, Dr. Abbott speaks of seeing the Black Alder loaded with its fruit resting upon the dazzling drifts of March snow. The Snowberries, white and red-fruited, are beautiful in autumn, but they also lose their beauty later in the year.

And the winter shrubbery can be enriched by many plants conspicuous by reason of their bark. Scarlet-twigged Dogwoods, Golden-barked Willows, the Kerria with its shining yellow branchlets and many others may be grouped with fruit-bearing plants to produce an effect of striking and of lasting charm. All these plants are beautiful in spring and summer as well as in winter, and some of them are among the most desirable shrubs for summer-planting that we have. Therefore it need not be thought that in planting for winter beauty we should detract from our pleasure at other seasons of the year. All we need to do is, while planting for summer, to think a little of winter too. A little thought will enable us without any sacrifice in other directions to produce delicate combinations of form and color upon which the eye will rest with satisfaction throughout the long weeks of snow and cold. It is ignorance or indifference rather than necessity that has led us to rely so entirely upon dusky evergreen foliage in our efforts after winter beauty.

The death is announced of Jules Emile Planchon, the distinguished Professor of Botany at Montpellier, at the age of 65. Although a systematic botanist by training, Planchon's predilections were for horticultural and economic botany; and of late years he has devoted himself specially to the study of the Grape-vine, and of its greatest enemy, the Phylloxera. He was sent to this country by the French Government in 1873, to prosecute these investigations; and on his return to Montpellier he made an interesting and valuable report upon the subject. His last important publication is a monograph of the Grape-vines and the other plants of the Ampelopsis Family, in which some new North American genera and several new North American species are proposed. This, the latest contribution to the botanical literature of the Grape, occupies the second half of the fifth volume of DeCandolle's Continuation of his Prodomus, for which Planchon had written a monograph of the Elms, Hackberries and other genera of the Nettle Family.

A Curious Vegetable Growth on Animals.

IT is a well known fact that in certain diseases of the skin and hair which occur in man and mammals there are found fungi of rather a low grade of organization which by many of the medical profession are considered to be the cause of the diseases. In many of the lower animals, also, parasitic fungi are found, so that the discovery of a new fungus growing on animals would cause little surprise. But the case is different in respect to algæ, lower plants which, unlike fungi, have green coloring matter in their cells. In a few animals which are low down in the scale of existence green algæ are occasionally found, but, in such cases, the algæ are not usually considered to be parasites in the ordinary sense. The algæ and animals are assumed rather to be living together in what is called a state of commensalism—that is, the algæ furnish in some way food for the animals while the latter provide food for the algæ.

A curious case in which algæ seem to live as parasites on animals has recently been studied by Mme. A. Weber van Bosse. It is a fact known to zoologists for some years that the hairs of some of the species of sloths have a greenish color. It had been suspected and partly demonstrated that the green color was due to some plant growth. The researches of Mme. Weber van Bosse show conclusively that such is the case, and she describes minutely and figures the species found in the hairs of *Bradypus* and *Choloepus*. The algæ described belong to two genera—*Trichophilus*, in which the cells are grass-green and give out zoospores like many small algæ found in salt and fresh water and also on trunks and trees in wet places; and *Cyanoderma*, in which the cells are violet colored like some plants of the Nostoc family. The home of the sloths is the damp, shady forests of the tropics, and there we might expect such algæ to grow on animals of a sluggish habit, especially if they live among the damp foliage of the branches, as is the case with the sloths. But we should hardly expect that those animals confined in the zoological gardens of Europe would have their hairs covered by the same algæ. Such, however, appears to be the fact.

W. G. Farlow.

Last Year's Leaves.

AS I walked yesterday along a wooded hillside, over tree-margined fields, and skirted a swamp too wet, as yet, to thread, I noticed many a tree with last year's leaves still on it. Except one Tupelo, which usually drops its foliage earlier than our other forest trees, these leaf-bearers were all Oaks or Beeches. Thoreau speaks of the White Oaks about Concord retaining their leave as a rule, and others deny that this is true, or more than an occasional occurrence.

The conclusions derived from my own memoranda, covering many years, and of my ramble of yesterday particularly, are that not only the White Oak, but several other species, do retain their leaves, or a considerable percentage of them, until early in May of the next year. Take any Oak grove in this neighborhood, and I think it will be found, if the trees are not too crowded for healthy growth, that fully three-fourths of them retain from one-tenth to one-half of their leaves. But when we come to consider single trees, this habit of leaf retention will be found one of many curious features. For instance, I know of many single trees, both Oaks and Beeches, that have a single limb that will retain its foliage the winter through, while the other branches are bare from November to May. Again, a tree that stands upon the edge of a wood will hold its leaves on the open, light and airy side, and drop those that grew upon the shaded limbs. Does the greater vigor of the foliage upon the sunny side explain this?

In one of my upland fields there stands a thrifty Scarlet Oak, that is noticeable for the beauty and density of its foliage. In October the deep green becomes a rich maroon, and later, a lighter and brighter red, and not until

nearly New Year's has the ruddy tinting given way to brown. Even then the tree remains a prominent object, and is, indeed, even for an Oak, one among a thousand. For the past fourteen years this tree has never failed to retain nearly all its leaves, although in that time there has been every variety of summer and winter that even the powers in charge of our capricious climate could invent.

On examination of the Oaks near by, it has seemed to me that they all have a tendency to retain their leaves, and the measure of success in each case is due principally to the exposure of the tree and its general vigor. Here I may be wholly at sea, and only too glad to be informed correctly, if in error.

What I have said of Oaks applies equally to the Beech. Given shelter from the north-west winds and average vigor, and many a leaf will cling to its parent stem, until the swelling leaf buds of the new year shall crowd it from its place.

While yet the drifts of the late great snow storm still lingered, it was a pleasant feature of the landscape to see the sapling Beeches still bearing aloft their last year's leaves, dimly glittering like wrinkled fragments of old gold, and filling the air with a bell-like tinkle, soothing and soft as the twitter of a bird.

I offer it as a hint to the landscape gardener, to bring about by selection, if it can be done, a fully established habit of leaf retention; not making evergreen Oaks, but winter-long, bright brown Oaks; for such now lessen, to a marked degree, the dreariness of many a winter outlook. Again, when leaf retaining Oaks are mingled with Evergreens, there is an added charm to the scene. Think for a moment of such a cluster as this: A background of Cedar, scattered Oaks with dark brown leaves, a Beech with golden foliage, and crimson-fruited Black Alder mingled through it all. This may be readily brought about, for I saw it yesterday, where Nature had, without man's aid or interference, made thus beautiful the corner of a long neglected field.

Charles C. Abbott.

Near Trenton, New Jersey, April 5th, 1888.

How the Mangrove Forms Islands.

AMONG the agencies that have helped to build up the peninsula of Florida may be numbered certain trees which are fitted by nature to grow on lands that are more or less under water and that are too unsubstantial to support other forms of vegetation. Like the coral builders, they work so slowly that in a single century no great change is accomplished, but in thousands of centuries the changes wrought are very great. The most important of these tree-workers are the Mangrove and the Cypress. The former grows on shores and shoals that are overflowed generally by salt tide-water; the latter in localities that are overflowed at times by fresh water. Both have similar obstacles to overcome and they accomplish by this very different means.

The Red Mangrove (*Rhizophora Mangle*) covers hundreds of square miles of the southern shores of Florida, the principal areas occupied by it being the shoals lying between the keys and the mainland—which are composed of calcareous sediment—and the low southern and western borders of the Everglades. In these localities and on tide-washed islands as far north as latitude 29°, it forms a dense thicket of vivid green, rising uniformly from high-water-level, unchanged by seasons, unaffected by hurricanes, insidiously encroaching on the domain of waters and helping build what in future ages will be dry land. Far in the interior, even on the northern border of the State, are found beds of calcareous sedimentary rock which may once have supported just such thickets of Mangrove.

In places on the mainland shores the Mangrove attains to tree-like dimensions, forming a tall trunk sometimes two feet in diameter. Like the Cypress, the Mangrove is provided with strong buttresses at the base, but these differ from those of the Cypress in being of the style called by

architects "flying" buttresses. Starting from the trunk a yard or two from its base, they descend in graceful curves, sending off branches, from which other branches proceed, all descending in similar curves to the muddy ground, over which the tides spread twice a day. These basal branches serve the double purpose of props and feeders. From the upper branches, aerial roots descend till they reach the water at high tide. Sometimes a tree may be seen entirely dead except as to one branch, which is kept green by sucking up water through an aerial root perhaps twenty feet long.

Another special provision for its environment is seen in the seed of the Mangrove. This, before falling from the branch, develops into a miniature trunk from six to twelve inches long. The basal end being the heaviest, it is most likely to strike the muddy surface first and to stick there in an erect position. The rootlets and seed-leaves being ready to push forth, the young plant makes a rapid growth and soon becomes well rooted and propped in its rather insecure position.

As the Mangrove usually grows, rising scarcely ten feet from the water and spreading laterally, the main stem is of little importance. Innumerable roots descend from and support the leafy branches, repeatedly forking in their descent and forming a sort of basket work below high-water-level. Floating objects become lodged in these natural weirs, shell-fish and other marine creatures multiply in them, and the submerged stems give support to sea-weeds and hydroids. In some localities the roots become encased with oyster-shells, and this, probably, is the origin of many of the oyster-bars that obstruct some of the lagoons or so-called rivers of southern Florida.

The Mangrove thickets in the course of time build up a foundation for other species. Of these none have a peculiar habit of growth, except the Black Mangrove (*Avicennia nitida*). This tree is remarkable as to foliage, fruit, wood, bark and roots. The surface-roots send upward innumerable short feeders, black, lithe and rising about a span above the surface. This function, evidently, is to draw nutriment from the water at high tide, and, like the knees of the Cypress, they add to the surface accumulations, which, from age to age, add to the elevation of the land. In this respect, however, neither of these trees equals the Red Mangrove.

The wood of the Red Mangrove sinks in water and is not attacked by marine worms. Hence, fallen branches and trunks remain where they fall, while material that floats in with the tide is detained by the network of basal branches. It is altogether probable that the thousands of tree-covered "islands" in the Everglades and Big Cypress were once Mangrove thickets and that the present Mangrove islands will in time be added to the mainland. As soon as they are elevated above the overflow of the tides, the Mangroves will give place to species that require only brackish soil, which, in turn, will be replaced by fresh water or inland forms of vegetation.

Jacksonville, Fla.

A. H. Curtiss.

Certain Cone-Eating Insects.

THE cases here mentioned are the only ones known to us where the cones of Spruce and Pines have been attacked by insects. It is well known that the Spruce bud louse (*Adelges abieticolens*) deforms the terminal shoots of the Spruce, producing large swellings, which would be readily mistaken for the cones of the same tree. Another species of bud louse (*Adelges abietis* Linn.), which appears to be the same as the European insect of that name, we observed several years since (August, 1881), in considerable numbers, on the Norway Spruces on the grounds of the Peabody Academy of Sciences at Salem. A species of caterpillar (*Pinipestis reniculella* Grote), was observed August 24th, in considerable numbers, on a young Spruce ten to twenty feet in height at Merepoint, on Casco Bay, Maine. The cones on the terminal shoot, as well as the lateral

upper branches, which, when healthy and unaffected, were purplish green and about one and one-quarter inches long, were, for the most part, mined by a rather large Phycid caterpillar. The worm was of the usual shape and color, especially resembling a Phycid caterpillar not uncommon in certain seasons on the twigs of the Pitch Pine, on which it produces large unsightly masses of castings within which the worms hide.

The Spruce cone worm is usually confined to the young cones, into which it bores and mines in different directions, eating galleries passing partly around the interior, separating the scales from the axis of the cones (Fig. 18). After mining one cone the caterpillar passes into an adjoining one, spinning a rude silken passage connecting the two cones. Sometimes a bunch of three or four cones are tied together with silken strands; while the castings or excrement thrown out of the holes form a large, conspicuous light mass, sometimes half as large as one's fist, out of which the tips of the cones are seen to project (Fig. 19). Besides these unsightly masses of castings, the presence of

Fig. 18.—Single Pierced Cone.

Fig. 19.—Mass of Infested Cones.

the caterpillars causes an exudation of pitch, which clings in large drops or tears to the outside of the adjacent more or less healthy cones. Where much affected the young cones turn brown and sere.

The same worms had also attacked the terminal branches and twigs of the same tree, eating off the leaves and leaving a mass of excrement on one side of the twig, within which they had spun a silken gallery in which the worm lived.

On removing the bunches of diseased cones to Providence, one caterpillar transformed in a warm chamber into a moth, which appeared the end of October; its metamorphosis was

probably accelerated by the unusually warm autumnal weather then prevailing. All the others had, by the 1st of November, spun within the mass of castings a loose, thin, but firm, oval cocoon, about half an inch long and a quarter inch wide, but the larvæ had not yet begun to change to chrysalids. Whether in a state of nature they winter over in the larval state within their cocoons, or, as is more likely, change to pupæ in the autumn, appearing as moths by the end of spring, remains to be seen.

I only found one tree next to my house thus affected by this worm. In 1887 the tree was not so seriously affected, though its general appearance had not much improved. It is probable that in a dense Spruce growth the trees would be less exposed to the attacks of what may prove a serious enemy of shade Spruces. The obvious remedy is, to burn the affected cones and mass of castings late in summer.

Fig. 20.—Spruce Cone-worm (enlarged).

The foregoing account has been taken from our fourth report on insects injurious to forest and shade trees, in Bulletin No. 13 of the U. S. Department of Agriculture, Division of Entomology, to which we are indebted for the accompanying illustrations, drawn by the artist of the Division, Miss L. Sullivan.

Another cone-eating insect is a bark beetle, *Dryocates affaber*. We have found this beetle in great abundance mining the bark of the Spruce, near the timber line on Gray's Peak, Colorado; it occurs, however, throughout the northern States. Mr. W. H. Harrington, of Ottawa, Canada, sent us, in December last, a specimen of this beetle (Fig. 21), which he doubtfully referred to this species, and which we find is identical with our Colorado examples. He has given us the following account of its habits: "The cones of the Pitch Pine were found to be, during the past season (1887), frequently inhabited by this bark borer,

Fig. 21.—Moth of Spruce Cone-worm (enlarged).

both beetle and larva. Their attacks were readily noticed by the small aborted cones. The terminal shoots of the branches seemed also sometimes infested by the same beetle. It seems larger than a beetle which I found a few years ago boring into the terminal shoots of the White Pine, and which you determined as *D. affaber*."

Foreign Correspondence.

The Kew Arboretum.—III.

BEFORE entering into a detailed account of the more important genera in the Kew Arboretum, it may be well to give a few particulars about some of the finer specimens, and a note or two concerning the history of others.

A fine Persimmon (*Diospyros Virginiana*) near the Temple of the Sun is one of the original denizens of the Old Arboretum, and was presented with many other rare and curious trees by the Duke of Argyle to George III; it is a handsome plant—apparently as happy as in its native habitat—and measures upwards of 60 feet in height, the trunk girthing 5 ft. 4 in. at a yard from the ground; the head has a spread of about 30 feet.

A conspicuous object at the present time (March) is a fine specimen of the Constantinople Hazel (*Corylus Colurna*) laden with catkins; it has a spreading head 44 feet across, is 35 feet in height, and the stem measures 4 ft. 3 in. in girth at three feet from the ground. According to Loudon this species was introduced to Britain in 1665; the following memorandum from "Hortus Collinsonianus" is worth reproducing. "The Turkey Nut, in the Mill Hill Garden, is very remarkable from all others, for the husk rises high, and branches out every way, and covers the nut. This is a remarkable acquisition, for the Captain that brought them from Turkey, eating them in a drinking room, one of them dropped into the crack of a rotten window board, where it took root; my gardening friend Mr. Bennett, coming there and seeing it, transplanted it to his garden, from whence our tree was a layer, and brought here anno 1756."

The history of the first introduced plants of the Chili Pine (*Araucaria imbricata*) is as follows. Towards the very close of the eighteenth century the officers of the Vancouver Expedition were at a dinner given in their honor by the Viceroy of Chili. Menzies, the surgeon and naturalist attached to the Survey, noticing that part of the desert consisted of nuts which were new to him, obtained a few which he planted in a box of earth on board his ship. Several germinated and five plants were safely deposited at Kew. These were grown under glass for many years, and the old Kew plant—perhaps the only survivor—even after being planted in its present position, was protected

by a wooden structure for many successive winters. Far more handsome specimens are to be met with than this—which dates from 1796—but its historical associations make it worthy of mention. It measures 34 feet in height and has a spreading round head quite similar in outline to those sketched in their native forests by Miss North; the stem is 3 feet 10 in. in girth at three feet from the ground.

The large *Sophora Japonica* near the newly constructed rockery for hardy Ferns is not only one of the original occupants of Aiton's Arboretum, but it is one of the three or four plants first introduced into Britain. It flowers profusely every year, but never seeds; although perfectly hardy our summers are not hot enough for pods to be developed. (In northern France do the same remarks apply. During a continental trip last August I saw no pods until I had got well into the southern districts beyond the Loire.) The Kew plant is about 50 feet in height, with a stem 13 ft. 6 in. in girth; it divides into numerous massive branches at about the height of a man and some of these are bound together by strong iron chains—the head has a spread of

when young. Possessing these advantages, it is not surprising to find that it is now being largely planted in many places.

Ginkgo biloba, the tree formerly only known in gardens as *Salisburya adiantifolia*, or the Maidenhair tree, is perfectly hardy at Kew and grows freely. Our largest specimen is upwards of 56 feet in height, with a head 42 feet in diameter, and a trunk 9 feet in girth at a yard from the ground. Formerly this specimen was trained against a wall like a fruit tree, but the building being removed the tree was left, and the side branches cut away. This tree, too, like many others which flourish well at Kew, does not flower, although it is on record that when enjoying the shelter of the wall it did produce male catkins.

The largest of the Turkey Oaks (*Quercus Cerris*) in the Kew Arboretum, is one growing near the Temple of the Sun. This was also presented by the Duke of Argyle. It is a noble specimen 85 feet in height, the spreading head being 96 feet through, and the trunk 15 feet 6 inches in circumference a yard above the ground. As a timber tree, in

Fig. 22.—*Rosa minutifolia*.

about 75 feet. Some other specimens at Kew are almost equally fine, and one, planted in a wood, where it had been prevented from developing too much laterally, has a fine clear stem of thirty or forty feet.

Not far from the *Sophora* just described is probably the finest Hop Hornbeam in the British Isles. This is not the Hop Hornbeam or Iron-wood of the north-eastern United States, but its European representative (*Ostrya carpinifolia*), and, in my opinion, a more ornamental species than the American plant. It is 50 feet in height, with a trunk 9½ feet in girth and a spreading head of upwards of 70 feet wide. This, although it is annually laden with its curious hop-like catkins, does not ripen seed at Kew.

The Corsican Pine (*Pinus Laricio*) near the Grand Entrance is a remarkably fine example of the species, and, moreover, has an interesting history. After peace had been proclaimed in 1815, it was brought to England by the botanist Salisbury. It was then a small plant, about six inches high, in a pot; the measurements now are: height 90 feet (several feet have been broken off the top by snow storms during the last dozen years); spread, 60 feet; girth of trunk at 4 feet from the ground, 9 feet. *P. Laricio* is a valuable timber tree, a fast grower, and stands the rough sea breezes well, besides being almost proof against game

Britain at any rate, this species is not of much value, but the South African forest authorities are planting it largely. The great importance of growing belts of Oak in the South African forests is that they are trees which by their dense shade keep down the grass, the burning of which does so much damage to the forests every winter. The Turkey Oak being better adapted to the climate of South Africa than the common Oak (*Quercus pedunculata*), its extended propagation is, according to the Conservator of Forests stationed at King Williamstown, of the first importance.

Royal Gardens, Kew.

Geo. Nicholson.

New or Little Known Plants.

Rosa minutifolia.*

OUR wild Roses have an ill reputation among botanists for the uncertainty which often attends the determination of their species. But there are some, fortunately, about which there can be no doubt, and we have

**R. MINUTIFOLIA*, Engelm. in Bull. Torr. Club, ix, 97. Of dense growth, 2 to 4 feet high, pubescent, with numerous scattered terete straight or slightly curved spines; leaves small, with narrow stipules, the leaflets 5, round to lanceolate, 1 to 5 lines long, incised-dentate; flowers an inch broad or less, pink or white, solitary on short tomentose peduncles terminating very short branchlets; receptacle globose, densely setose-hispid, the calyx-segments cleft, persistent; styles distinct.

here given the figure of one which carries its distinctive characteristics obtrusively to the front, and cannot be mistaken. Not only is there no other American Rose like it, but it stands alone in the genus, forming M. Crepin's section, *Minutifoliae*. Its compact habit, its very small and deeply toothed leaflets, and its small, solitary flowers almost sessile upon the short branchlets, together make it a very distinct species.

As might be expected, this Rose belongs to the flora of the Pacific coast. It has been found only on the peninsula of Lower California, near All Saints (Todos Santos) Bay, about 40 miles south of San Diego, where it was discovered in 1882, forming low, dense thickets upon the dry hillsides bordering the shore. It is a much-branched, compact shrub, armed with numerous stout, straight spines, the small leaves often fascicled, and with numerous pink or white flowers along the branches. The globular base of the calyx is covered densely with short bristles. Evidently the flower in its wild state cannot be commended as well suited to the florist's needs, but from its habit of growth the plant may well prove a decided ornament to the lawn and garden in our more southern States, where it would doubtless be hardy. S. W.

Cultural Department.

A Selection of Lilies.

THE selection of varieties is an individual work to be settled by the grower in accordance with his personal taste and the amount of space and money he has at command.

For a garden of moderate size the twelve species and varieties named below would well represent the whole family and furnish continued bloom from June until September.

Lilium auratum, the golden-banded Lily of Japan, is one eagerly sought, because of its large, showy flowers. As a garden flower it has few equals, if magnificent display is the object sought. As a cut flower for house decoration it is the least desirable of any of the family. It is too large to arrange with others, with a due regard for harmony of form and color, and the fragrance it exhales is truly sickening. Of this species there are many garden varieties, differing only in the markings. In some the golden band gives place to one of bright crimson, which for a day is showy, but the crimson soon fades into a dirty brown and the beauty of the flower vanishes. None of these varieties equal the original type. This is usually considered a difficult subject to manage. Choose the smallest bulbs, those that are heavy and firm, plant deeply, say eight inches, in the driest part of the border, in partial shade, and the bulbs will last a number of years.

L. elegans is sold in many forms under the name of *L. Umbellatum*, and its varieties, *atrosanguineum*, *fulgens*, etc. Orange is the predominating color, with various shades; a few are deep crimson and quite showy; some are a clear citron in color; some are self-colored, others deeply spotted. Alice Wilson, a variety of recent introduction, is decidedly the best of its class. The flower is perfect in form, with petals broad, full and gracefully curved. Its color is a clear, lemon-yellow, deepening towards the centre of the flower to a rich golden yellow. The class is valuable, because of earliness, hardiness, and profusion of bloom. A large clump makes a magnificent display. The flowers are generally too coarse for table or parlor decoration.

L. Brownii, which is also known as *L. Japonicum*, a native of China, is remarkable for its long trumpet-shaped flowers, ivory-white inside, and dark purple on the outside. This is usually regarded a tender Lily, and is not much grown because of its liability to perish. This opinion is quite erroneous. I know a clump of more than a hundred bulbs, all of which have come from six bulbs planted some ten years ago in a raised bed, which has not since been disturbed. Many of the bulbs furnish eight flowers each, and the display is such as only this stateliest of flowers can make.

L. candidum, the old and well-known white Lily of our gardens, is the one we could least afford to lose. For graceful habit, stainless purity, and delightful fragrance it has no peer. It is fitted for any place, and for all occasions where cut flowers are desirable. It is about the only flower we do not like to cut, and that because it is too noble and pure to meddle with. This bulb should be removed in August, and not be suffered to remain long out of ground; it commences its autumn growth the last of August, and upon this growth its next year's bloom

depends. A blight has visited the Lily in many parts of this country, the cause of which no one has been able to discover, neither has there been found for it a remedy.

L. excelsum, or *testaceum* of many catalogues, is another noble Lily closely allied to the *L. candidum*, and resembling it in habit of growth. Its flowers are drooping, with reflexed petals of a delicate nankeen color, with the minor petals covered with darker warty spots. Its fragrance is delicate and pleasing.

L. speciosum, or, as it is more commonly known, *L. lancifolium*, is the most useful of all the Lilies. In point of beauty it ranks next to *L. candidum*, and is far more useful when cut. Of this species we should not be content with less than four varieties. Var. *præcox* is a strong grower, producing when well established twelve to fifteen very large, pure white flowers on a single stem, with regular and much reflexed petals often clasping the stem; in the centre of the flower the petals are studded with delicate little projections, like crystal points. Var. *purpuratum* has the same general habit, but is a taller and stronger plant, with dark rose-crimson flower whose petals, at the base, are seemingly rugged with rubies and garnets, while the edges are bordered with white. Var. *punctatum* differs in habit of growth but little from those already noticed, its flowers being pure white, delicately studded with light rose-colored spots. Var. *roseum*, or *rubrum*, is the most common and best-known of all the varieties. Much confusion exists in regard to its variety name. Some dealers call it *roseum*, others *rubrum*, many send it out under both names; the result is, if you buy one you have both, if you buy both you have but one, which one it matters but little. Its color is between that of *L. punctatum* and *L. purpuratum*. There are nearly fifty varieties of this species catalogued; the four described are fairly representative, and for a general display no more are required, while for a good collection neither could well be omitted.

L. longiflorum, the trumpet-shaped Lily, is conspicuous among Easter flowers, as it is well adapted for forcing. The popular Bermuda Lily belongs to this species. It thrives well in the open border, but it is folly to plant it unless thoroughly protected against frost.

L. tenuifolium is the earliest of all Lilies to bloom in the open border and one of the most remarkable, because of its brilliant scarlet flowers, borne in terminal clusters on very slender stems, which are beautifully clothed with grass-like foliage.

L. tigrinum flore pleno, although one of the much despised Tiger Lilies, is, when well grown, a noble and beautiful plant. I have had a single plant grow more than five feet high, with a diameter of more than three feet, bearing in a single season more than sixty flowers, and continuing in bloom fully six weeks. The flowers are orange-scarlet and very double.

Finally, let me say, that in making a selection one cannot well go wrong, for there is not a species or variety that is unworthy of a place in the garden. You will succeed if you deserve success, and you will be sure to increase the number of varieties annually. You will also observe that your investment has been relatively small, as plants that are steadily and rapidly increasing in number, though they may cost one dollar each when you begin, are, in the end, much cheaper than those that require to be removed every year, like all the popular bedding plants. C. L. Allen.

Kitchen-garden Notes.

ASPARAGUS.—For private use, plant in rows 3 to 4 ft. apart, 18 to 24 inches asunder in the row, and the top of the crowns 5 inches below the surface of the ground, which we do not raise into ridges at all. Marketmen plant 2 to 4 inches deeper, and in spring plow the earth from between upon the top of the rows in order to get white shoots. By sowing some seed in spring, we can keep up a supply of plants for new plantations or for filling up gaps in old ones.

BEANS.—In light, sandy land sow snap beans about the 17th or 20th of April, but it is not safe to sow them before the 24th. Valentine is the best of green-podded varieties; it does not rust or spot; Golden Wax is the best of the yellow-fleshed kinds.

BEETS.—Sow Egyptian or Eclipse in rows a foot apart.

CABBAGE.—As soon as young plants of early Wakefield are well hardened off, plant them out in rows 2 ft. apart.

CARROTS.—Sow a little Early Horn, Scarlet Stump-rooted and Danvers—the first a foot apart, the others 15 or 18 inches.

CAULIFLOWER.—Treat like Cabbage, only be more careful in having the plants well hardened off and the ground warm and rich; indeed, if the plants can be well taken care of, and the out-door conditions are not quite favorable, delay planting till about the 20th. Early Snowball is best.

CELERY.—Sow some Golden Heart and White Plume in a cold-frame. I do not sow the main crop till the last week in April, but this will be too late for less favored localities.

CUCUMBERS.—Sow Tailby's or Nichol's on sods or in pots in a hot-bed and plant out in May.

EGG PLANTS AND PEPPERS.—Keep them growing in pots in hot-beds, snug and warm and well covered up at night. They are very tender. There is nothing better than New York Improved Egg Plant or Ruby King Pepper.

LETTUCES.—Those sown last week in March in hot-beds are now fit for transplanting. Set them out among other crops, say between Cabbage and Cauliflower plants or between rows of Peas. Sow again, this time out-of-doors, for succession. Salamander and White Summer Cabbage are good for summer use. Every kind of Lettuce will fail in hot weather.

ONIONS.—For seed Onions select well-manured rich ground. After it has been well pulverized, tread or roll it to make it firm, then draw drills an inch deep and 15 to 18 inches apart; sow, cover and tread or roll. I prefer Yellow Danvers, Southport White Glove and Wethersfield Red. Or for early use plant sets, and the larger they are, the earlier they will be fit to use.

PARSNIPS.—Sow a little seed now and the main crop about three weeks later. Use deeply-worked rich soil, and have the rows 20 or 24 inches apart. Get the Student or Long Smooth.

TURNIPS.—Make a small sowing once a fortnight. I much like the Strap-leaved sorts, also Purple-top White Globe. Early sowings are much troubled by worms in the "bulb."

HERBS.—Have some Mint, Thyme and Tarragon growing permanently; and from seed every spring raise some Chervil, Savory and Sweet Basil.

Fruit Garden Favorites.

AMONG the old Strawberries none please me so well as the Downing. There are more highly flavored varieties, and those more beautiful, but there is something in the quality of the Downing that leads me each season to the spot where it grows. Under good culture it is large and productive, but in some localities it is subject to leaf blight, so called, caused by a fungus growth.

Next to the Downing for the amateur I would place Mt. Vernon. It is attractive in flavor, productive and vigorous, but too soft for market. This, like many others, has been overlooked by many, in the crowd of new varieties that have been offered, yet it has friends everywhere, and will be planted more

The Alameda of Chihuahua. *Populus Fremontii*, Var.—(See page 105.)

PARSLEY.—Sow a row of Double Moss Curled at once in good ground. Old roots are persistently running to seed. Raise a fresh supply every year. For wintering in frames sow again about midsummer; this sowing will not "bolt" till next spring.

PEAS.—Sow nothing but wrinkled marrow Peas. Alpha sown now will give peas fit for use about the 10th of June; McLean's Advancer, about the 15th or 25th, and Stratagem about the 20th. Owing to season and conditions of cultivation these dates may vary. Sow all these varieties on the same day and with successions of Stratagem or Champion of England every ten days. Champion is the best Pea grown—but it is too tall.

RADISH.—Sow a small row once a week; they are fit for use four weeks after sowing. French Breakfast as a Turnip Radish, and Wood's and Chartier's as long Radishes, are good.

RHUBARB.—A barrel set over the stools will draw up the leaf stalks long and tender. Cut out flower stems as soon as noticed.

SPINACH.—Use Viroflay or Long Standing, make a small sowing once in ten days. Use Spinach as a catch crop between Cauliflower, Parsnip rows, or wherever else there is room.

TOMATOES.—Keep them growing vigorously in pots in frames. Give them plenty head and root room.

and more each season by those who appreciate a good Strawberry. Triomphe de Gand and Jersey Queen are both superior in quality to either Downing or Mt. Vernon, but usually will not yield half as much fruit, and in many localities are exceedingly fickle. Indeed, the Durand strain of Strawberries, to which Jersey Queen belongs, has proved uncertain with me as a rule, and also with many others. Parry and Jewell, of the same strain, while among the best of the family, are variable, the Jewell far more so than Parry, the latter proving to be a valuable early variety in many localities. It varies greatly in quality, however, in the same row the same day, a peculiarity which I have not noticed in any other variety. Among the newer varieties Jessie excels in quality united with productiveness, and Bubach in size, beauty and vigor.

It is a disputed question whether Strawberry beds should be cultivated during the spring, or bearing season, but weeds must be subdued, and shallow hoeing early in the season does no harm. Where the winter mulch is left between the rows it has a tendency to cause later ripening and increases the danger from frost, but otherwise the mulch is beneficial. If the soil is not fertile enough commercial fertilizers may be applied by hand, if care be taken not to permit them to touch the foliage. They should be mixed with the soil at

once with the hoe. The Strawberry is a good feeder, and wood ashes, nitrate of soda, common phosphates or almost any fertilizer will be acceptable. The proper time to apply, however, is before planting, and I would select yard manure if I could have my choice. The earliest berries will be found on the sunny side of dry knolls, or adjoining tight board fences, or timber belts that afford protection. A cold-frame with glass over a portion of the bed will cause those thus covered to ripen before their less favored sisters.

It is not easy to explain why Raspberry and Blackberry plantations deteriorate when the dead canes are not removed, but such is the fact. Possibly the dead wood absorbs too much moisture from the roots. I often renew an old plantation by mowing off both dead and living canes close to the earth while the soil is frozen, hoeing and fertilizing afterward. As the plants attain age they throw up too many canes, thus causing the small berries found on old plantations. We often thin out the bearing canes on old plantations one-half. These fruits, and in fact most fruits, abhor an undrained soil. Wet land is the principal source of failure with the Raspberry and Blackberry. It is the cause of winter killing and feeble growth. Last season many Raspberries turned brown and withered before ripening, lessening the crop one-third. The severe freezing of the previous winter enfeebled the plants. On high, dry lands less loss of this character was observed.

Patrick Barry used to say that the quality of a Black Raspberry was hardly worth considering, but I think he would not say so now, for the varieties differ greatly in quality. Mammoth Cluster is among the best, and Gregg is most deficient in quality. Red Raspberries differ in quality as much as apples. There are few who enjoy the better varieties, as they are not hardy, but they can be easily protected. Franconia possesses many of the good qualities of the better class of red, and Brinckles' Orange of the yellow. In Blackberries the old Lawton and Kittatinny have not been excelled in size and quality, but it must be remembered that they are seldom permitted to ripen fully. If eaten as soon as they color they suggest sips of vinegar or lemon juice, but a week later they soften and are sweet as wild honey.

Rochester, N. Y.

Charles A. Green.

Peat Muck for Trees or Lawns.—The cleanings of ponds, or peat-muck dug out of the swamps, if carted into a heap on dry ground and left there for one or two winters to freeze and pulverize, is then in capital condition to mix with soil for trees and shrubs. Indeed, it is the best thing we can add to the soil for this purpose. It has an excellent effect on nearly every kind of loamy, gravelly or sandy soils. Its free use on clayey lands renders them more open and congenial to tree and other plant roots, and less liable to bake and crack in summer. On gravelly and sandy land it has an ameliorating and fertilizing influence; besides, it enables the land to hold manure better than it did before the muck had been used. Jarvis Field—the base-ball grounds at Harvard College—was leveled, graded and laid down fresh to grass some years ago. The land is very sandy; indeed, so sandy, that, unassisted by clay, loam or muck, a good stand of grass could not be produced and retained on it. As any quantity of muck could be had conveniently, it was freely used, and a good sward secured. The idea is sometimes entertained that about as much muck as manure will be sufficient. But in preparing holes for trees, one-fourth the bulk of the soil of muck will be little enough. On sandy land for grass, a layer three to six inches deep all over, and this well plowed and harrowed into the ground, but still kept near the surface, will be none too much. But muck alone will not retain a vigorous sod; surface-dressings of manure should also be used. Lawns, in making which muck has been freely used, should be well rolled early every spring, else the frost will leave their surface puckered and uneven.

W. F.

Transplanting the Arbutus.—The trailing Arbutus is so rarely seen in cultivation that there is some color for the prevalent opinion that it is difficult to transplant. If there is a serious disturbance of the root the plant nearly always dies, but I have transplanted it many times with perfect success. The work has always been done in early spring, just after the flowering is over. A trowel or spade is run down well around the plant, so that a good ball of earth comes with it. Sturdy, small, bushy plants are the best. Of course a shady place should be selected for it. I once set a plant among some rocks in a hollow, shaded by trees; another time at the foot of a small hillock facing north, in both of which situations it flourished and flowered. About Philadelphia the east bank of the Wissahickon is a favorite spot for this plant, but the city is spread-

ing over the Wissahickon hills and is closing in upon its hiding place. This means that the Trailing Arbutus, and many another wild beauty, will soon be lost to us. *Joseph Meehan.*

Petalostemon decumbens is one of the good hardy herbaceous plants that bloom in May. Its flowers are borne in dense spikes of rose throughout the summer. It is one of the legumes, and very distinct, rare and beautiful. It is most suitable for the alpine garden. An established plant will cover nearly a square yard; and as it dies back every fall to an unbranched woody rootstock, from which all decumbent flowering stems arise, it remains much of the same size and condition for years, and can never become a nuisance like some other pretty plants, by becoming too obtrusive. It reaches a height of six or eight inches.

T. D. Hatfield.

The Forest.

The Forest Vegetation of Northern Mexico.—II.

Populus Fremontii, var. *Wislizeni*, *Watson Cottonwood*.*—Though the impression was purposely conveyed in the preceding article that the high plains of North Mexico are destitute of arborescent vegetation, a few unimportant exceptions must be mentioned. Conspicuous among these is this Cottonwood, which rears high its rounded head of abundant bright green foliage, in striking contrast throughout most of the year with the gray and brown tints of the surrounding landscape. This tree is not abundant, because water is not abundant; for it is a sure index of the presence of living water either on the surface of the soil or not far below it. It grows scattering along streams or clustered about springs. Its centre of distribution is on the Rio Grande, and it follows this river northward to its upper waters in south Colorado and the tributaries of this river from whatever direction into their narrower mountain cañons. Westward it ranges along the boundary quite to the Pacific, and southward extensively through the valleys of Mexico, and there often carried by man considerably beyond its indigenous limits.

Cheering to the traveler over heated and dusty hills and plains is the sight of its shining leafage with promise of refreshing shade and water. The Mexicans seem to regard this tree with sentiments similar to those cherished by the Orientals for the Palm or the New Englander for the Maple. They plant it by the water, convenient to which they have built their dwellings, and set it along their irrigating ditches. No visitor to Mexico but has noticed and admired that peculiar feature of Mexican cities, the avenue of grand old Poplars, double-lined on each side it may be, kept alive and flourishing, if on high ground, by streams of water conducted along the rows. The Spanish name for the Cottonwood—for any species of Poplar, in fact—is *Alamo*, that for this avenue *Alameda*, a noun having the form of the perfect participle—that is to say, the Poplared place.

Perhaps it is owing to this sentiment as much as to his proverbial inertia, that the Mexican so generally withholds his axe from his *Alamos*. I have never seen the tree systematically pollarded for firewood in Mexico, as is the practice of Americans in southern California. Seldom is it robbed of its branches, unless they are wanted for planting. In this matter, as in so many others, the Mexican shows his lack of enterprise. His scanty supply of fuel is mostly gleaned amongst Scrub Oaks of mountain sides or the paltry shrubbery of mesas, and brought by pack trains of donkeys through ten or twenty weary miles, when much of it might be grown on stumps along the waste borders of the valley stream or in its torrent-swept gravel.

Nevertheless, when necessity compels, the *Alamo*, yielding in many places almost the only procurable timber of much size, serves, as I have seen, for the few purposes besides fuel required by these simple people—for beams of inferior quality to support the earth covering of the poorer dwellings, mere mud hovels, for crotched posts of bough-covered porches and sheds attached to these, for the huge bars and bar posts and the stockade of corrals for cattle,

* See illustration, page 104.

and even in the construction of the wheels, frame and pole (each six or eight inches thick) of the cumbersome carts of the country.

Associated with the Cottonwood, one sometimes meets with a few scattered specimens of *Salix nigra*, the Black Willow, in size and aspect, as well as in species, identical with the common Willow of the United States. Its tough, strong and easily worked wood is used by the Mexicans for making saddle-trees.

Salix irrorata, a Willow which, among the mountains of Colorado, grows but six or eight feet high, sometimes in Chihuahua follows the streams from mountain cañons down to the plains, and makes in alluvial soil a small tree.

Salix taxifolia, here, as in Southern Arizona, at home along the gravelly alluviums of streams, makes a small tree with a single straight trunk.

Fraxinus pistaciifolia, the Mexican Ash, often comes out of the mountains in the same way, and in fertile, well-watered valleys makes a large and beautiful tree, two to three feet in diameter and fifty or sixty feet in height. Therefore it is often planted along with the Cottonwood in towns and about the *haciendas* of the rich. The quality of its timber, however, is far inferior to that of the northern White Ash.

Sambucus Mexicana, the Mexican Elder, sparsely scattered through bottom-lands, attains a diameter of nearly a foot and a height of fifteen to twenty. With its rotund head of dense, deep-green foliage, its white flowers and its edible fruit, it often gains a place about Mexican houses.

Juglans rupestris, the Black Walnut of the Southwest, frequently leaves mountain cañons, even following down *arroyos* dry throughout most of the year. Its average diameter in such situations is twelve to eighteen inches and height twenty to thirty feet. With its low, wide-spreading branches, covered with smooth, light-gray bark, it resembles, when not in leaf, the fig-tree. Its nuts, less than an inch in diameter, when freed from their rind, are too meagre to be much prized even in a country where there are no nut-bearing trees except Oaks and Pines.

Celtis occidentalis, var. *reticulata*, the Hackberry in similar situations, a small tree about a foot in diameter at best, is the only remaining arborescent species of the high northern plains worthy of mention.

C. G. Pringle

Notes on the Norway Pine.

THIS pine is at home in Minnesota. The young trees have the sturdy appearance of the Scotch and Austrian pines, and would they not with equal care prove more beautiful? Cold does not warp the leaves, while the White Pine and the White Cedar have a pinched and frozen appearance with a temperature of 40° F.

The groves of mature trees of Norway Pine form a green roof supported by bronze pillars; light, open, and breezy; in marked contrast with the dark and brushy White Pine woods. The Norway cannot rival the queenliness of the mature White Pine, however. Norway pine is the hardest and most productive timber produced on the sandy and gravelly ridges and knolls of northern Minnesota. Three measurements of Red Pines are as follows:

Age.	Diameter in inches three feet from the ground.	Feet of lum- ber, board measure.
* No. 1	36 years	12
101 " "	19	360
† No. 2	36 " "	13½
101 " "	23	640
‡ No. 3	19 " "	9
140 " "	20	580

* Injured by fire during fifteenth year.

† Near foot of hill, fifty feet from other Norway trees.

‡ Average tree.

"Jack Pine" (*Pinus Banksiana*) is the natural nurse of Norway pine timber in this region.

H. B. Ayres.

Correspondence.

To the Editor of GARDEN AND FOREST:

I am glad to see that an experienced and learned planter like Mr. Dana condemns in such unmistakable language the Norway Spruce. No tree (for no other foreign tree has ever been so generally planted) has ever so injured the appearance of our plantations. But it is surprising that Mr. Dana, with all his observation and experience, should find any praise for the Austrian Pine. This is certainly one of the poorest trees ever introduced into this country. It is only necessary to see the specimens which were planted in the Central Park, in this city, twenty-five or thirty years ago, to be convinced of this. They vie with the Norway Spruces and Scotch Pines in their shabby and disreputable appearance. These three are the most unsatisfactory trees which have ever been planted in America. The fact that they are very hardy, and grow very fast during a few years, only makes their subsequent want of vigor the more disappointing. The Austrian Pine pushes out vigorously when it is young, but even in its best days it appears lumpy and heavy. As it gets older it grows thinner and thinner, borers attack the trunk, and branches die and fall off. Even in the mountains of southern Austria, where the species flourishes, it is never a large or picturesque tree, and no wise man will ever plant it with the expectation of its lasting more than a few years. Our native Red or Norway Pine is the best substitute for either the Scotch or the Austrian Pine; just as our native White Spruce is the best substitute for the Norway Spruce. The Red Pine is a graceful tree of agreeable color and rapid growth; it is very hardy and will flourish on poor soil.

Why does not Mr. Dana mention the Douglas Fir, which now promises to become one of the most valuable of all our ornamental Conifers? It has proved itself to be an exceedingly valuable and attractive tree in England, where there are specimens more than one hundred feet high. It has been cultivated in this part of the United States for a quarter of a century, or since its discovery in Colorado, and there is not one of the new Conifers which now promises so much.

Among the foreign trees which Mr. Dana extols is *Abies brachyphylla*. The color of this plant is a beautiful dark green, and it grows upward with great vigor, but its strength is in the top. The lower branches are weak (and this is true of the nearly related *A. Veitchii*) and become overshadowed by those above. The result will be that plants of this species by the time they are twenty or twenty-five years old will be bare at the bottom as a specimen of *Abies firma*, the most unsightly of Conifers in this climate. But there are other Japanese Conifers of the greatest merit and much promise which I should like to add to Mr. Dana's list. At the head of these I place *Picea Ajanensis*, which in most collections is cultivated under the erroneously applied name of *P. Alcockiana*, another and much less desirable species of northern Japan, closely related to, if not identical with, the Siberian *P. obovata*. *Picea Ajanensis* is perhaps the handsomest Spruce which can be grown in this climate, for, unfortunately, we cannot have in perfection the lovely and graceful Himalayan Spruce, *P. Smithiana*. Another Japanese Conifer of great beauty and promise is *Thuja Japonica*, improperly called in most gardens *Thuyopsis Standishii*. *Pinus parviflora* is a small and graceful White Pine which should find a place in every collection. It is perfectly hardy; and so too is the Corean Pine, *P. Koraiensis*, one of the most desirable and attractive of the five-leaved Pines. It is never a large tree, but is a very beautiful one, and is better in color even than our native White Pine, and much denser in appearance, as it retains the leaves on the branches during three or four seasons instead of for a single year. The other Japanese Pines, *P. Thunbergii* and *P. densiflora*, are very hardy, but they have no ornamental value. There are several other Conifers which should promise well in this climate, such as *Pinus Murrayana* and *P. monticola*, from the mountains of western America; *Pinus Peuce* and *Picea Omorika* from south-eastern Europe; *Abies Davidiana*, from northern China, which will probably turn out to be a second species of *Keetleria*, and several others. I hope Mr. Dana will give your readers his experience with these and other plants in his large and interesting collection.

New York City, April 8th.

Strobilus.

[We are glad of an opportunity to publish the experiences of planters with new trees. They should all be planted here and carefully tested. The introduction of one first rate tree will repay a thousand failures. It must be borne in mind, however, that we really know very little yet about Japanese and many other exotic Conifers, and still

very little about those from Colorado—much less than we did about the Norway Spruce, when it was thought to be the best Conifer that could be planted in America. The time may come when we shall learn that they are all unreliable. It takes a long time to test the adaptability of a tree to a peculiar climate, and such experiments should be carried on in public establishments, where time and the chances of failure are not important elements, or by individuals who are willing to devote their time and money to such experiments for the sake of the experiments themselves. It is to such planters that we owe in this country most of our knowledge of foreign trees. Those persons who cannot afford to make experiments or run risks with their plantations should plant only such trees as have been thoroughly tested and are known to flourish in this country.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—In the inhospitable climate of New England, the first sight of the fragile flowers of the Hepatica with its delicate hues, opening in some sheltered spot, before the Winter has fairly gone, always brings a thrill of delight.

Bigelow, in his "Florula Bostoniensis," thus gracefully speaks of the Hepatica: "This delicate little plant is one of the earliest visitors in spring, flowering in sunny spots before the snow has left the ground. The flowers appear on hairy scapes before the leaves. Petals oblong obtuse, purple, sometimes white." It is, however, more especially as an indication of the comparative earliness of different springs that I wished to speak of this flower, having recorded its first appearance in the same locality and mostly on the same plants, for the past twenty-six springs.

The following are the dates in the several years :

April 26th, 1863.	March 30th, 1876.
" 24th, 1864.	" 11th, 1877.
" 2d, 1865.	" 10th, 1878.
" 15th, 1866.	April 5th, 1879.
" 7th, 1867.	March 2d, 1880.
" 19th, 1868.	April 3d, 1881.
" 11th, 1869.	March 5th, 1882.
" 10th, 1870.	April 1st, 1883.
March 19th, 1871.	" 13th, 1884.
April 12th, 1872.	" 15th, 1885.
" 8th, 1873.	March 18th, 1886.
May 3d, 1874.	" 21st, 1887.
April 11th, 1875.	" 23d, 1888.

Chestnut Hill, Mass.

D. D. Slade.

To the Editor of GARDEN AND FOREST :

Sir.—Will some reader of GARDEN AND FOREST tell me if a Savin would grow under the shade of a Horse-Chestnut whose lowest branches are ten feet from the ground. The grass is poisoned by the drip. Blue Laurel or Periwinkle does well under similar circumstances. If Savin is unsuitable what can be planted? Could Honeysuckle or Jackman Clematis?

Providence, March 29th.

Ivy —.

[Undoubtedly the best plant to grow under the dense shade of a Horse-Chestnut tree is the Periwinkle, which thrives in such situations and makes an attractive appearance throughout the year. If this plant is used the space under the tree to be covered should be carefully forked over and enriched with well rotted stable-manure, and if a dressing of fresh soil can be added it will greatly improve the bed. Strong, well rooted plants only should be set twelve to eighteen inches apart. They should be freely watered during the first season, as the roots of the Horse-Chestnut will absorb a great deal of moisture and so make the surface soil dry. Dwarf Junipers or "Savins" would suffer from drought and shade and give little satisfaction in such a situation, and so would Honeysuckle or Clematis. The Rose of Sharon, or Aaron's Beard (*Hypericum calycinum*), a dwarf and very beautiful, almost evergreen shrub from south-eastern Europe, is very generally used in England to clothe the ground under the shade of trees. It is admirably suited for this purpose, but in New England, except, perhaps, in the extreme southern part, it would require a slight protection in winter. We shall be glad to

hear of the experience of our readers with this plant, which is not sufficiently known or appreciated in this country.—Ed.]

To the Editor GARDEN AND FOREST :

Sir.—It is well known that the old *Azalea Indica alba* is perfectly hardy as far north as New York City, and also that *Azalea amena* and its relatives are hardy. But who knows that other varieties of the showy Indian Azaleas are not hardy? These plants have always been high priced, and growers have not experimented with them much in the open air. There is here an opportunity for some of the new experiment stations to do a good turn for landscape gardeners by making tests of the hardiness of all these showy plants. I am inclined to think that there are many hard-wood green-house shrubs that can be grown in the open air further north than we now imagine. Trees of *Citrus trifoliata*, which I planted in northern Maryland eight years ago, bore fruit last year, as stated by a correspondent of the *American Farmer*. These trees the first year they were planted went through a cold wave, in which the mercury fell to 18° below zero, without the loss of a twig. The fruit of this *Citrus* is about the size of a green Walnut with the hull on, with thick skin and is bitter to the taste. It is good, however, for marmalade. The trees, with their golden fruit, are highly ornamental, and when leafless they are still attractive from the bright green color of the bark. This Orange is a valuable plant for hedges on account of its dwarf and dense growth and terrible thorns. When the seed becomes more plentiful it will no doubt take the place of all other hedge plants where it is hardy. Here also is work for experiment stations in raising hybrids of a more or less hardy nature by crossing this hardy Japanese species with the varieties that bear luscious fruit in Florida. It is not impossible that in this way the Orange belt might be moved much north of its present limit.

Miller School, Va.

W. F. Massey.

[Experiments in testing the hardiness of trees and shrubs are made continuously in this country in both public and private establishments, and one of the duties of GARDEN AND FOREST is to record and make known the results of such experiments as soon as they appear conclusive. The trouble with the Indian Azalea as an out-door plant, even very much further south than this latitude, is, that while it may be sufficiently hardy to withstand the cold of ordinary winters, it has not the reserve strength of constitution to enable it to survive the exceptionally cold waves which pass over this country every few years. South of Virginia the Indian Azalea is one of the most beautiful shrubs which can be grown, as March and April visitors to Mr. Drayton's charming gardens near Charleston can testify; and it is surprising that this plant is not more often seen in our Southern cities. North of Virginia the Indian Azalea should only be planted as an experiment, and with the expectation that unusually cold weather will kill it outright, or at least cut it down to the ground. *Citrus trifoliata* is hardy here; at least a plant has grown and flowered freely in a sheltered spot in the Central Park for many years. This little Orange, however, must be grown more extensively before its perfect hardiness at the North is demonstrated.—Ed.]

Flower and Fruit Pictures at the Academy of Design.

THE flower and fruit paintings which may now be seen at the Academy of Design cannot, as a whole, be included among the pictures which give the exhibition its character as the best that has yet been held. They are not very numerous, and a diligent search reveals scarcely half-a-dozen which can be called even tolerably good. The best American painters of flowers are not represented—neither Mr. LaFarge nor Mr. Alden Weir, both of whom paint flowers beautifully in the most poetic way, and neither Miss Greatorex nor Mr. Carlsen, both of whom are singularly successful in treating them from the decorative point of view. Several ambitious attempts at a decorative treatment of showy flowers may be found. But Mrs. Dillon is not up to her usual level in either her "Roses" or her "Chrysanthemums"—both being painted in a soft, cottony fashion. Mr. C. C. Coleman, too, is hardly up to his average in his picture of purple Magnolias in a purple

jar (ugly enough to have been Rosamond's in Miss Edgeworth's famous story), relieved against a purple velvet hanging—his flowers are painted with little tenderness or charm, and his color scheme is sombre and unattractive. And as for Mr. John F. Weir's large picture of Peonies, it quite deserves that an action for libel be brought against it.

Little variety is shown in the choice of subjects. Roses and Chrysanthemums preponderate—the best being Mr. Ramsey's pink and yellow Roses on a pink cloth, and Mr. Binford McCloskey's yellow and white Chrysanthemums against a dark red background. But neither of these pictures is remarkable, and not much can be said in praise of any of the Hollyhocks, Pansies or Geraniums, which include almost all the other flower paintings. The best of them are very prosaic in effect, and if prose in painting is ever to be condemned as such, it must surely be in the case of pictures of flowers—unless, of course, they are intended to have a merely documentary, scientific value, in which case the higher canons of art cannot be applied to them. The very essence of a flower that is worth painting at all is that it has poetic quality of some kind—either of the bold, brilliant and emphatic kind which touches sentiment on its more sensuous side, or of the idyllic, subtle kind which touches it in its tenderest and most delicate fibres. There is music in the blare of trumpets as well as in the tones of a violin; and so there is pictorial poetry in Chrysanthemums and Peonies as well as in the Wild Rose and the Narcissus. And whoever paints either the one or the other without translating and accentuating this sentiment, fails in the essentials of his task, however correctly he may seem to have drawn and colored, however gracefully he may have grouped his flowers. From this point of view there seemed to me only one really good piece of flower painting in this exhibition—Miss Conkey's simple little picture of pink Chinese Primroses in a broken basket has much more true sentiment in it, more truth to the charm of its subject, more tenderness and poetry than any of the others.

The fruit pictures, among which I beg leave to include two or three excellent pictures of Onions, are much better as a rule than the flowers. Mr. W. J. McCloskey has done excellent technical work in his little painting of Tangerine Oranges wrapped in white papers; Mr. Conely's "Pan of Apples" is very good; and Mr. Harry Eaton's "Fruit"—Oranges and black Grapes on a white cloth—is admirable. There is very clever handling in it, and there is also the great desideratum—a touch of true pictorial sentiment.

If it seems to be difficult to paint flowers well, and especially Roses, what must it be to carve them in marble? Yet even this task is not beyond the power of a good artist. The Roses which the lady holds in her hand whom Mr. St. Gaudens has portrayed in a marble low-relief, are absolutely perfect in their truth to the grace, the delicacy and the poetry of the flower.

M. G. van Rensselaer.

Recent Plant Portraits.

ODONTOGLOSSUM CRISPUM GOUVILLEANUM, *Revue Horticole*, March 16th.

PRUNUS CAPULI, *Revue Horticole*, March 16th. The plant here figured appears to be *Prunus serotina*, which is sometimes seen in French nurseries under the name of *P. Capuli*, a Mexican and South American tree for which the oldest published name is *P. salicifolia*.

CRASSULA LACIEA, *Gardener's Chronicle*, March 10th.

BEGONIA LUBBERSII, *Gardener's Chronicle*, March 10th.

PHALÆNOPSIS, John Seden, *Gardener's Chronicle*, March 17th. A hybrid raised in the establishment of the Messrs. Veitch from *P. amabilis* of Blume, crossed with the pollen of *P. Laddemanniiana*. The flower is described as "three inches in diameter, ivory white, densely and uniformly spotted all over both sepals and petals with small dots of a beautiful light purple, the lip suffused with light rosy purple."

CARYOTA SOBOLIFERA, *Gardener's Chronicle*, March 17th.

HYACINTHUS CORYMBOSUS, *Bulletino della R. Societa Toscana di Orticultura*, February. A dwarf purple-flowered Cape species.

PEAR; PIERRE TOURASSE, *Bulletino della R. Societa Toscana di Orticultura*, February.

TEA ROSE; MADEMOISELLE FRANCISCA KRÜGER, *Journal des Roses*, March.

GLADIOLUS OBERPRÖSIDENT VON SEYDERRETZ; *Gartenflora*, March. A semi-double and not very attractive variety.

BEGONIA LUBBERSII, *Revue de l'Horticulture Belge*, March. A showy Brazilian species with pale flowers and beautifully marked foliage.

ODONTOGLOSSUM INSLEAYI, var. LEOPARDINUM, *Revue de l'Horticulture Belge*, March.

VANILLA FLOWER AND ITS FERTILIZATION, *Bulletin, Royal Gardens, Kew*; March.

URENA TENAX, *Bulletin, Royal Gardens, Kew*; March. A valuable fibre plant from Natal.

Retail Flower Markets.

NEW YORK, April 20th.

Trade is generally good throughout the city. It is brisk in Broadway shops that catch the cream of it, as a rule. The supply of cut flowers is very full, yet really choice flowers are scarce. Only perfectly grown Roses, that have not been injured after having been cut, will satisfy the patrons of florists in first-class localities; but selected hybrids bring 75 cts. The average run of them are sold for 50 cts. Puritan Roses cost 40 cts. Very large La France—and there are some grand specimens brought in from Hudson River localities—are offered for 50 cts. each. There are quantities of indifferently grown ones arriving, which bring \$3 a dozen. Catherine Mermets have improved in quality; they sell for \$2 and \$3 a dozen. Bride Roses are 20 cts. each, and Perles des Jardins, Souvenir d'un Ami, Papa Gontier and Niphetos cost \$1 a dozen. There are a limited number of Papa Gontiers arriving, which are very large and handsomely colored, that bring \$2 a dozen. Mde. Cusins costs \$1.25 a dozen and William Francis Bennetts are \$1.50. There is a glut of *Lilium longiflorum*, the best of which are sold for \$3 a dozen. These flowers were disposed of for \$5 a hundred early in the week, at wholesale. Callas cost 25 cts. each. The average Lilies-of-the-Valley of indifferent quality bring 75 cts. a dozen, and the best bring \$1. Tulips, Daffodils, Roman Hyacinths and Poet's Narcissus cost 75 cts. a dozen. Cut spikes of Dutch Hyacinths sell for \$1.50 a dozen. Daisies are 25 cts. a dozen, and Meteor Marigold is 50 cts. a dozen. Mignonette is very handsome, and brings from 50 cts. to \$1 a dozen. Both white and purple Lilacs are of excellent quality, and are in good demand at \$2 a bunch. Violets are opening their eyes, and becoming poor. They bring from 75 cts. to \$1.50 a dozen. Orchids are so scarce that the shops show none. Gardenias bring \$3 a dozen. Smilax is 40 cts. a string, and *Asparagus tenuissimus* is 50 cts. a yard.

PHILADELPHIA, April 20th.

There has been no serious break in the flower market, no glut, since the heavy Easter traffic, owing to the numerous dinners, receptions, weddings and other festal gatherings in society. Good flowers are plentiful, excepting Lilies-of-the-Valley. The price of these, however, remains at \$1 per dozen. Tulips are steady at the same quotation. Owing to the great numbers of the single Trumpet Daffodil which are now blooming freely in the open air, the price has dropped to 50 cts. per dozen; Van Sion, the double variety, which can only be obtained in quantity from green-houses, holds to the price of \$1 per dozen. Plants in full flower of varieties of *Primula vulgaris* are becoming more plentiful. The strain in cultivation here is now so mixed by cross fertilization, that it is difficult to distinguish the Polyanthus of our youth from the English Primrose, or, rather, we have Polyanthuses with flowers of the English Primrose. They are very showy and beautiful. One of the most effective uses to which they can be put is, when growing in two-and-one-half or three-inch pots, to arrange them as growing plants in plateaus for dinner-table or other decorations. Forget-me-not is used in the same way. Jacqueminot Roses sell at \$3 per dozen. American Beauty, Mrs. John Laing, Baroness Rothschild, and its white variety, Merveille de Lyons, sell at from \$4 to \$5 per dozen. French Marguerites sell at 25 cts. per dozen; Carnations 35 cts.; Astible 50 cts. per dozen sprays. Smilax remains scarce. *Asparagus tenuissimus* is plentiful and very fine. At a recent dinner an effective centre piece was a flat, circular basket, five feet in diameter, filled with Callas, from which yellow Tulips arose.

BOSTON, April 20th.

The cut flower market continues in an unsettled condition, the result principally of over production. The past winter has been unfavorable to heavy cropping, this being especially true regarding Roses, and now the plants seem to be bent on making up for lost time. So flowers are too plenty and prices unusually low. But this condition is not caused by a reduced demand, for it is very evident from the number of buyers, and the enormous quantities of flowers handled, that flowers are not in the least losing their hold on our people. Corsage bouquets of Roses and spring flowers are very generally worn on the street, and have become almost an essential part of a lady's theatre costume. Such varieties as the Poet's Narcissus, Mignonette, Forget-me-not and Violets are extremely popular for this purpose. There seems to be a very general dislike of strong-scented flowers. Dutch Hyacinths, which are now abundant, are almost unsalable, for no other reason, apparently, than their heavy odor. Though offered in almost every color of the rainbow, and dazzlingly brilliant in mixed collections, these good qualities seem to count for nothing. Violets are getting quite small, as they always do on the approach of warm weather, but they are not abundant, and sell readily for 75 cts. per bunch. Roses remain as at last report, with a downward tendency in prices. Carnations, like Violets, are seen reduced in size, and they are abundant and cheap. Lilies of all kinds are offered in large quantities at low figures. They make more show in large decorations than anything else that can be obtained at present for the same price. Bulbous flowers of all kinds are plenty. In general, the prices and quantities of flowers offered are such that, for the present, at least, no one need be without them.

American Cemeteries.

THERE is nothing in this country to which foreign writers give more praise than to our cemeteries. The student of social customs sees in them one of the chief proofs we give of genuine sentiment on the one hand and wise sanitary foresight on the other; and the student of art and nature sees in them our most characteristic and best achievements in the art of landscape gardening. Their size, their park-like arrangement, their remoteness from the local centres of population, and the care and neatness with which they are kept, are held up to foreign communities as points in which they would do well to imitate us. Certainly, as contrasted with the formal, walled-in, crowded, dreary, sun-baked or weed-grown cemeteries seen in most foreign lands, ours deserve much praise. But they are not what they ought to be. Excellent in intention, they are too often bad in execution. No expenditure of money, pains or skill is wanting, but in directing this expenditure we too often make grievous errors.

The cause of these errors, as one of our contributors has recently pointed out, is that we do not abide by the general idea with which the place was set aside for this special service. The characteristic feature of American cemeteries is that they are rural, no matter how large may be the communities for which they serve. But this characteristic we do our best to conceal or destroy. Nature is asked to take our dead in charge, and then we do a thousand things to ruin the repose, the sanctity and beauty which she is ready to provide. Too many and too prominent roads and walks are made, giving the cemetery the aspect of a place for pleasure promenades rather than for the retirement of those whose dead it holds. We take pains to make ample allowance of space to each purchaser of ground, partly that for his sake the graves shall not be too closely crowded and partly that they shall not destroy the unity and repose of the landscape. And then we often nul-

lify our efforts by enclosing the lots with heavy railings and by building huge and showy monuments. We think we want a natural landscape, and then we plant the cemetery—not the private lots alone, but the parts which have been preserved intact for the sake of landscape beauty—with tropical plants, formal beds of gaudy flowers, and ribbon-patterns, borders, and endless puerile devices, wrought with bright-foliaged plants, which only support our climate a few weeks or months and then disappear, leaving dreary nakedness behind. In short, we lose sight of the main purpose for which the cemetery was designed, fail to keep any general idea or scheme in mind, and instead of a rural burial-ground produce something which is a meaningless, unnatural and essentially vulgar compound of a cemetery, a park, a horticultural exhibition and a collection of works of architecture and sculpture. And this we do by means of a vast waste of pains and money. No one who has not inquired into such matters can imagine what it costs to plant out year by year the exotics which are supposed to adorn our cemeteries, and to winter them from one year to another. Few realize the degree to which cemetery companies now compete with one another in this direction, bidding for public patronage by means of costly horticultural establishments and verbose advertisements of their horticultural resources and achievements. All this is wrong—wrong from the point of view of good sense, from the point of view of true sentiment, and from the point of view of art. The true ideal for the making of an American cemetery, whether large or small, is this: That spot should be selected of which the natural charms are greatest in direction of peacefulness and the harmony which means variety in unity. Its features should be as carefully preserved as possible in laying out the walks and drives, which should not be more numerous than actually required for purposes of burial and of visiting the graves. Such planting as is needful should be done in a way to complete the existing beauty, and accentuate, not disturb, the natural character of the spot. Costly exotics should not be introduced, no showy flower-beds allowed, no formal arrangements of planting of any kind permitted. They are out of keeping alike with the kind of beauty that is desired and with the spirit in which a cemetery is properly visited. Owners of lots should not be allowed to surround them with railings. They are palpably useless; they are glaringly injurious to unity and repose of effect; they serve merely to display proprietorship, and nothing can be in worse taste than such a display in such a place. Owners should be encouraged, too, to make their monuments not only as artistic, but as simple and unobtrusive as possible. Only a great man, one to whose grave future generations are likely to make pilgrimages, is entitled to have his resting place conspicuously marked; and even he does not need that it should be thus marked. Something which will indicate where a body lies and whose body it is, while disturbing as little as possible the unity and peacefulness of the scene—this is what a grave-stone should be. It is needless to say that color as well as form should be considered with this fact in mind. Granite is the best possible, our favorite white marble the worst possible, material for cemetery monuments; and a flat slab is preferable to a vertical shaft or stone. If large boulders chance to be strewn over the ground nothing is more appropriate for monuments, a simple inscription being cut upon a space made smooth for the purpose, while the rest of the moss-grown or vine-covered surface remains in its natural condition. Owners should be restrained in their desire to plant showy flowers about the graves—should be taught that it is not justifiable for them to indulge their personal wishes in this way if they conflict with the greatest good of the greatest number as provided for in the peaceful unity of aspect that the cemetery as a whole should have. And finally, while the cemetery should be carefully kept and tended, there must be no evident straining after excessive finish as the most desirable of all qualities in all portions of the grounds.

Plans for Small Places.

MORE than once the request has come to us to publish a plan for a small suburban building lot, and to this the natural reply has been: "What lot?" Such plans cannot be furnished like ready-made clothing, in assorted sizes and warranted to fit any piece of land. Even from a cultural point of view no list of plants for a given place can be recommended unless its soil, aspect, drainage and other physical conditions are known and considered. And of course the territory lying about and beyond the lot, together with the relation of these surroundings to the lot itself, suggests problems of prime importance. What disagreeable or incongruous objects are to be planted out of sight? What outlook is to be preserved and made more pleasing by a proper treatment of the foreground? What are the tastes and necessities of the family which is to occupy and use the house and grounds? These and a hundred other questions must be met with specific answers in every given instance.

It does not follow from this that all general plans, of which so many have been published, are useless. The best of them have been made with a view to solve some special difficulties. They contain helpful suggestions and illustrate principles which are of wide application. But after all, no plan, however perfectly it may be adapted to one location, can be repeated with the same success in another. The attempt to reproduce effects in landscape work that have been agreeable elsewhere is invariably disappointing. To follow a fashion in gardening is rather more displeasing than to copy second-hand ideas in any other art. And even if it were not desirable in every case to produce something original, characteristic and appropriate, all efforts at imitation must prove but parodies, because growing plants develop into infinite variety. No two trees or shrubs—still less two groups of trees or shrubs—can be exact duplicates. The same selection and arrangement of plants at opposite ends of a village street will make pictures totally unlike in spite of the most painstaking effort to nurse them into a uniform effect.

When, therefore, we requested Mr. Olmsted to prepare a plan for an unpretentious homestead, we expected him to choose a lot with a character of its own and explain how he would adjust it to the wants and tastes of a particular household. The value of this study is not alone that it shows how difficulty can be converted into opportunity, and a strong-featured piece of ground on an abrupt hillside with cramped and irregular boundaries can be turned into a desirable building lot. In a broader way it is useful as illustrating the class of problems that present themselves whenever thorough work of this kind is contemplated, and as illustrating, too, how these problems are solved by a trained and conscientious artist.

Cut Flowers and Growing Plants.

IN Mr. Peter Henderson's article on "Floriculture in America," published in the first number of this journal, he spoke of the great love of Americans for cut flowers, and contrasted it with the love of the residents of foreign cities for growing plants. The difference which he notes, and which he illustrates by instructive figures, must strike every keen observer of national habits and tastes. There is nothing in London or Paris to rival the display of cut flowers in our florists' shops in winter. But, on the other hand, we have nothing which even approaches in magnitude or beauty the spectacle afforded at every season of the year by the plant markets of Paris. The surroundings of the Church of the Madeleine, on certain days of the week in spring and summer, offer one of the traditional sights which every tourist feels bound to see when he first visits Paris; and even stay-at-homes are familiar with the brilliancy of the scene, for there is none which has more often attracted the brush of the painter. French artists of the moment are especially fond of paint-

ing the streets of Paris, and if their gift lies in the direction of brilliant color, where could they turn for a better subject than to these crowded pavements, where gaily dressed ladies and children and white-capped nurses thread the rows of gorgeous blossoming plants, to bear away, now a huge yellow Chrysanthemum, or a tall red Rose-tree, and now a tiny pot, bought for a couple of cents, of Forget-me-nots or Pansies? And in every one of our home exhibitions of art, especially in those devoted to water-color painting, the individual plants of the French flower-market are brought beneath our eyes, each enveloped in one of those great cones of stiff white paper without which no self-respecting Parisian plant would be seen in public. But where shall one go in New York to find such scenes?

In Germany, although such gorgeous out-door displays of plants as we find in Paris are less common, there are always plenty of market-booths in the public squares where blooming plants may be bought in great variety; and in winter very beautiful specimens may be had from every florist. In the latter weeks of winter Azaleas are the favorites, and during all the preceding weeks Crocuses and Hyacinths, Lilies-of-the-Valley and Cyclamens, as well as Roses, are grown and sold in vast quantities. The custom of sending flowers as gifts to friends is very popular in Germany, although it has, of course, never been carried to such extravagant lengths as with us. But even more often than cut flowers, flowering plants are used for the purpose—either a single fine specimen, solitary in its pot, or a group of flowers of the same kind, or a pretty arrangement of contrasting kinds grown in round, wide, shallow, inexpensive baskets of bark. Such a basket filled, for example, with Hyacinths of different colors, or with a variety of Tulips, or with a pure white mass of Lilies-of-the-Valley, is more beautiful than any bunch of these flowers; and it will last much longer even in the atmosphere of a hot, dry living-room. Not the most splendid bunch of Roses is more lovely than a fine Azalea in full flower; and if the plant is purchased in bud and left to flower in its new owner's possession, she will be sure of several weeks' instead of several hours' enjoyment.

We have no wish to find fault with the love of cut flowers, which is so distinctively an American characteristic. Yet we think our almost exclusive preference for them instead of for flowering plants is a misfortune, especially to persons of modest means, who, by a different expenditure of their money, might buy more lasting pleasures.

The wood of the Liquidambar has now become an article of considerable commercial importance in this country. As long as black walnut and cherry were abundant and cheap it was considered worthless by the manufacturers of furniture, but now more than three million feet are annually used by them in this city alone. Blocks of this wood have been employed for several years in paving the streets of some western cities, and in the South liquidambar shingles have long been common. This wood is nearly as heavy as black walnut, but not as strong; it is tough and close-grained and can be made to take a beautiful satiny polish. Its color is bright brown tinged with red. This wood, however, shrinks and splits badly in seasoning and this is its great defect. But it has now been found that if the wood, as soon as it comes from the saw, can be steamed for fifteen or twenty hours, according to the thickness of the boards, and then carefully kiln-dried, it will not warp or twist. This is a discovery of great importance and is likely to have a considerable influence upon the lumber supply of the country. The Liquidambar is a large, and in some parts of the country a very common tree. It frequently reaches a height of a hundred feet with a trunk diameter of over six feet. It flourishes in the low and often inundated river-swamps of the South and West, where, mixed with the Cottonwood and the Big Tupelo, it covers vast areas which can never be brought under cultivation from lack of sufficient drainage and will always remain

in forest. These river-swamps, too, will always be protected from fire by the moisture of the soil. Our store of liquidambar, therefore, will not be very soon exterminated probably, and, if cut judiciously, will supply the demand of furniture manufacturers for a long time to come.

Few people, probably, realize the extent of the plantations of American Grape-vines which have been made in Europe since the discovery that they have sufficient vigor to survive the attacks of the Phylloxera, and therefore make the best stocks upon which to work the different wine-grapes in regions affected by this pest. From a recent issue of the *Revue Horticole* it appears that in the year 1881 about 22,000 acres were planted in France with American Grapes, while in 1887 not less than 416,000 acres were planted, the total acreage for these seven years amounting to 1,200,000 acres. These figures give an idea of the immense damage the Phylloxera has inflicted upon French agriculture.

Plan for a Small Homestead.

Conditions and Requirements.—The site is upon the south face of a bluff, the surface of which is so steep that the rectangular street system of the city, to the east and south, had not been extended over it. The diagonal streets, *M* and *N*, have been lately introduced and building lots laid off on them, as shown in Figure 1. The triangular space between *L* and *M* Streets is a public property containing the graves of some of the first settlers of the region. Its northern and western parts are rocky and partly covered by a growth of native Thorns and Junipers, east of which there are Willows and other planted trees. At *A* there is a meeting-house and parsonage. Arabic figures show elevations above city datum.

The lot to be improved is that marked *IX*. The usual conveniences of a suburban cottage home are required, and it is desired that it should be made more than usually easy and convenient for members of the household, one of whom is a chronic invalid, to sit much and be cheerfully occupied in out-of-door air and sunlight. A small fruit and vegetable garden is wanted and a stable for a single horse and a cow, with carriage room and lodgings for a man. Water for the house, garden and stable is to be supplied by pipes. There is a sewer in *M* Street.

The problem is to meet the requirements thus stated so snugly that the labor of one man will be sufficient, under ordinary circumstances, to keep the place in good order and provide such gratification of taste as with good gardening management the circumstances will allow.

The north-west corner of the lot is 21 feet higher than the south-east corner, the slope being steeper in the upper and lower parts than in the middle. There is a small outcrop of a ledge of limestone about 30 feet from the south end, and the ground near it is rugged and somewhat gullied. *M* Street, which has a rapid descent to the eastward, opposite the lot, was brought to its grade by an excavation on the north side and by banking out on its south side the bank being supported by a

retaining wall. The excavation has left a raw bank two to five feet high on the street face of the lot.

Looking from the middle part of the lot over the roof of the parsonage a glimpse is had of a river, beyond which, in low bottom land, there is a body of timber, chiefly Cottonwood, over which, miles away, low, pastured hills appear in pleasing undulations.

The narrower frontage of lot *IX*, its irregular outlines, its steepness, its crumpled surface, the raw, caving bank of its street face and its apparent rockiness and barrenness, had made it slower of sale than any other on the hill streets, and it was, accordingly, bought at so low a price by its present owner that he is not unwilling to pay liberally for improvements that will give him such accommodations upon it as he calls for. From the adjoining lots and those higher up the hill to the north the view which has been referred to, over the roof of the parsonage, is liable to be curtained off by trees to grow, or houses to be built, on the south side of them. Either this liability has been overlooked or the view has been considered of little value by those who have bought them. "Most people," says the owner of lot *IX*, "find their love of Nature most gratified when they have a trim lawn and a display of flowers and delicacies of vegetation upon it in front of their houses. I find Nature touches me most when I see it in a large way; in a way that gives me a sense of its infinitude. I like to see a natural horizon against the sky, and I think that the advantage we shall have here in that respect will fully compensate us for the want of a fine lawn-like front, provided the place can be made reasonably convenient." Fortunately his wife is essentially like-minded. "I am a Western woman," she says, "and would not like to live in a place that I could not see out of without looking into the windows of my neighbors."

Controlling Landscape Considerations.—The only valuable landscape resource of the property lies in the distant view eastward from it. Looking at this from the house place, it can evidently be improved by placing in its foreground a body of vigorous, dark foliage, in contrast with which the light gray and yellowish greens of the woods of the river bottom will appear of a more delicate and tender quality, and the grassy hills beyond more mysteriously indistinct, far away, unsubstantial and dreamy. Such a foreground can be formed within the limits of lot *IX*, and, strictly speaking, the forming of it will be the only landscape improvement that can be made on the place. It is, however, to be considered, that when the middle of the lot is occupied by a house but small and detached spaces will remain to be furnished with verdure or foliage, and that anything to be put upon these spaces will come under direct and close scrutiny. Hence nothing should be planted in them that during a severe drought or an intense winter or in any other probable contingency is likely to become more than momentarily shabby. Further, it is to be considered, that when the eye is withdrawn from a scene the charm of which lies in its extent and the softness and indefiniteness, through distance, of its detail, the natural beauty in which the most pleasure is likely to be taken will be of a somewhat complementary or antithetical character. But to secure such beauty it is not necessary to provide a series of objects the interest of which will lie in features and details to be seen separately, and which would be most enjoyed if each was placed on a separate pedestal, with others near it of contrasting qualities of detail, each on its own separate pedestal. It may be accomplished by so bringing together materials of varied graceful forms and pleasing tints that they will intimately mingle, and this with such intricate play of light and shade, that, though the whole body of them is under close observation, the eye is not drawn to dwell upon, nor the mind to be occupied, with details. In a small place much cut up, as this must be, a comparative subordination, even to obscurity, of details, occurring as thus proposed, and not as an effect of distance, is much more conducive to a quiescent and cheerfully musing state of mind than the presentation of objects of specific admiration.

Anatomical Plan.—The important common rooms of the family and the best chambers are to be on the southern side of the house, in order that the view over the river, the southwestern breeze and the western twilight, may be enjoyed from their windows. (See figure 2.) It follows that the kitchen and the main entrance door to the house are to be on its north and east sides. Were it not for excessive steepness, the best approach to the house would be on a nearly straight course between its east side and the nearest point on *M* Street—i. e., the south-east corner of the lot; this partly because it would be least costly and most convenient, and partly because it would make the smallest disturbance of the space immediately before the more important windows of the house. But to get an approach of the least practicable steepness the place will be entered

at the highest point on *M* Street—*i. e.*, the south-west corner; then a quick turn will be taken to the right, in order to avoid the ledge, then, after passing the ledge, another to the left. On this course a grade of one in twelve and a half can be had. (The grade on the shortest course would be one in seven.) Opposite the entrance to the house there is to be a nearly level space where carriages can rest.

The caving bank made by the cut for grade of *M* Street requires a retaining wall four feet high along the front of the lot. This will allow a low ridge, nearly level along the top, to be formed between the wheelway and the street, making the wheelway safer and a less relatively important circumstance to the eye.

Even in the part of the lot chosen, as being the least steep, for the house, a suitable plateau for it to stand upon can only be obtained by an embankment on the south and an excavation on the north. The embankment is to be kept from sliding down hill by a wall ten feet in front of the wall of the house. This retaining wall is to be built of stained and crannied, refuse blocks of limestone which have been formerly thrown out from the surface in opening quarries on the back of the bluff. They are to be laid without mortar and with a spreading base and irregular batter. Where the ledge can be exposed they will rest upon it, and the undressed rock will form a part of the face of the wall. A railing two and a half feet high is to be carried on the top of the retaining wall, and the space (*b*) between this and the wall of the house will be an open terrace upon which will open half-glazed French windows on the south of the library, parlor and dining-room. At *c* (figure 2) there is to be a little room for plants in winter, the sashes of which are to be removed in summer, when the space is to be shaded by a sliding awning. At *d* a roof covers a space large enough for a tea table or work table, with a circle of chairs about it, out of the house proper, forming a garden room. This roof is to be sustained by slender columns and lattice-work, and lattice-work is to be carried over it and the whole to be overgrown with vines (Honeysuckle on one side, Wistaria on the other, the two mingling above). The space *ee* is reserved for a tiny pleasure garden, to be entered from the house and to be considered much as if, in summer, it were a part of it carpeted with turf and embellished with foliage and flowers. At *f* there is to be a retired seat for reading and intimate conversation, and east of this an entrance to the service gardens, to be described later. The laundry yard, *h*, and the kitchen yard, *i*, are to be screened by high lattices covered by Virginia Creeper. The court yard, *jj*, is to be smoothly paved with asphalt blocks or fire brick, which it will be easy to thoroughly hose and swab every day. In one corner of it is a brick ash house, *k*; in another a gangway to the cellar and a chute for coal, *l*; in another a dog house, *m*. The stable and carriage house are entered from the court yard, but hay will be taken into the loft from a wagon standing in the passage to the back lane. At *n* is the stable yard.

Landscape Gardening.—The soil to be stripped from the sites of the house, terrace, stable, road and walks, will be sufficient, when added to that on the ground elsewhere, to give full two feet of soil wherever needed for turf or planting.

Trenches, nowhere less than two feet deep, are to be made on each side of the approach road south of the terrace and to be filled with highly enriched soil, the surface of which is to slope upward with a slight concavity as it recedes from the approach. The base of the wall is to merge irregularly into this slope. The space between the terrace and the street is so divided by the approach, and, in the main, is so steep and dry, that no part of it can be well kept in turf, nor can trees be planted in it, because they would soon grow to obstruct the southward view from the house and terrace. The steep dry ground and the rock and rough wall of this space are to be veiled with vines rooting in the trenches. The best vine for the purpose is the common old clear green Japan Honeysuckle (*Lonicera Halliana*). In this sheltered situation it will be verdant most, if not all, of the winter, and blooming, not too flauntingly, all of the summer. It can be trained not only over the rough sloping wall of the terrace, but also over the railing above it, and here be kept closely trimmed, so as to appear almost hedge-like. Also it may be trained up the columns of the shelter and along its roof; the odor from its bloom will be pleasing on the terrace, and will be perceptible, not oppressively, at the windows of the second story. Other vegetation is to be introduced sparingly to mingle with it, the wild Rose and Clematis of the neighborhood; the Akebia vine, double flowering Brambles, and, in crevices of the wall, *Rhus aromatica*, dwarf Brambles, *Cotoneaster microphylla*, Indian Fig, Aster, and Golden Rod, but none of these in conspicuous bodies, for the space is not too large to be occupied predominately by a

mass of foliage of a nearly uniform character. Near the south-west corner of the pleasure garden, *Forsythia suspensa* is to fall over the wall, and, also, as a drapery in the extreme corner (because the odor to those near the bloom of it is not pleasant), Matrimony vine (*Lycium vulgare*). Upon the walls of the house east of the terrace, Japanese Ivy (*Ampelopsis Veitchii*) is to be grown, and before it a bush of the fiery Thorn (*Crataegus Pyracantha*). For the ground on the street side of the approach, *pp*, smooth-leaved shrub evergreens would be chosen were they likely to thrive. But both the limestone soil and the situation is unfavorable to them. Next, a dark compact mass of round-headed Conifers would best serve the purpose of a foreground to the distant view, but there are none that can be depended on to thrive long in the situation that could be kept within the required bounds except by giving them a stubbed and clumsy form by the use of the knife. The best available material for a strong, low mass, with such deep shadows on the side toward the terrace as it is desirable to secure, and which is most sure to thrive permanently in the rather dry and hot situation, will be found in the more horizontally branching of the Thorn trees (*Crataegus*), which grow naturally in several varieties on other parts of the hill. Their heads may be easily kept low enough, especially in the case of the Cocks spur (*C. Crus-galli*), to leave the view open from the terrace without taking lumpy forms. But as a thicket of these spreading thorn bushes, fifty feet long, so near the eye, might be a little stiff and monotonous, a few shrubs are to be blended with them, some of which will send straggling sprays above the mass and others give delicacy, grace and liveliness, both of color and texture, to its face. Common Privet, red-twigged Dogwood, common and purple Barberry, *Deutzia scabra*, Spice-bush and Snowberry may be used for the purpose. American Elms have already been planted on the lot adjoining on the east. The Wahoo Elm (*Ulmus alata*) and the Nettle tree (*Celtis occidentalis*) are to be planted in the space between the approach and the boundary. They will grow broodingly over the road, not too high, and mass homogeneously with the larger growing Elms beyond. Near the stable two Pecans (*Carya oliviformis*) are to be planted. The three trees last named all grow in the neighboring country and are particularly neat and free from insect pests. A loose hedge of common Privet having the effect of a natural thicket is to grow along the boundary. No other shrub grows as well here under trees.

As the pleasure garden is to be very small, to be closely associated with the best rooms, and to be not only looked at but used, it must be so prepared that no excessive labor will be needed (as in watering, mowing, sweeping and rolling), to keep it in superlatively neat, fresh and inviting condition. No large trees are to be grown upon or near it by which it would be overshadowed and its moisture and fertility drawn upon to the injury of the finer plantings. It must be easy of use by ladies when they are shod and dressed for the house and not for the street. Its surface is to be studiously modeled with undulations such as might be formed where a strong stream is turned aside abruptly into a deep and narrow passage with considerable descent. It will be hollowing near the house and the walk, and will curl and swell, like heavy canvas slightly lifted by the wind, in the outer parts. Wherever it is to be left in turf the undulations are to be so gentle that close mowing, rolling and sweeping will be easily practicable. The upper and outer parts are to be occupied by bushy foliage compassing about all the turf; high growing shrubs next the fences and walls; lower shrubs before them; trailers and low herbaceous plants before all. But there must be exceptions enough to this order to avoid formality, a few choice plants of each class standing out singly. The bushes are to be planted thickly, not simply to obtain a good early effect, but because they will grow better and with a more suitable character in tolerably close companionship. As the good sense of the lady who is to be mistress of this garden ranges more widely than is common beyond indoor matters of taste, it may be hoped that due thinnings will be made from year to year and that the usual mutilation of bushes under the name of pruning will be prevented.

The following little trees and bushes may be used for the higher range: The common, trustworthy sorts of Lilac, Bush-honeysuckle, Mock-orange, Forsythia, Weigelia, the Buffaloberry (*Shepardia*), common Barberry, the Cornelian Cherry and the red twigged Dogwood. In the second tier, Missouri Currant, Clethra, Calycanthus, Jersey Tea, Japanese Quince, Japanese Mahonia, Spiræas, and the Mezereum Daphne.

In the third tier, *Deutzia gracilis*, Oregon Grape, flowering Almond (white and red), *Spiræa Thunbergii* and *S. Japonica*, Waxberry, *Daphne Cneorum*, small-leaved Cotoneaster, and the Goatsbeard Spiræa. The Virginia Creeper is to be planted against the walls of the house, Chinese Wistarias near the

garden room. Oleanders, Rhododendrons, Figs, Azaleas and Bamboos, grown in tubs, are to be set upon the terrace in summer. They are to be kept in a cold pit during the winter.

The service garden (gg, Fig. 2) will have a slope of one to five inclining to the south. It is intended only for such supplies to the house as cannot always be obtained in the public market in the fresh condition desirable, and is divided as follows:

- g 1. Roses and other plants to provide cut flowers and foliage for interior house decoration;
- g 2. Small fruits;
- g 3. Radishes, salad plants, Asparagus, Peas, etc.;
- g 4. Mint, Parsley, Sage, and other flavoring and garnishing plants for the kitchen,
- g 5. Cold-frame, wintering-pit, hot-beds, compost-bin, manure-tank, garden-shed and tool-closet.

BROOKLINE, MASS., 14th April, 1888.

Fred'k Law Olmsted.

forces well even earlier than the present date, and I imagine that it would be invaluable for market florists. It is one of the *Rosa polyantha* hybrids of which Ma Parqueritte and Anna Maria Montravel are other beautiful examples.

Among other noteworthy flowers were the new Cinerarias, shown by Mr. James, who for several years past has made the improvement of this flower the study of his life. He has changed starry flowers into perfectly circular flowers with overlapping florets, besides impressing into his "strain" new self-tints, and combinations of tints, in zones and stripes. Some critics hold that the improved Cineraria has lost the elegance and beauty of the old-fashioned Cineraria in the severely symmetrical flower. But the balance of opinion among florists is in their favor, and this strain of seeds always commands the highest prices, which is a fair test of popular favor. The very finest varieties are named, and, of course, are propagated from cuttings, though in some cases the sorts are perpetuated true from seed. There was a large gathering of these flowers on exhibition and of the three sorts certificated the finest was a pure white with purple centre, named Maria. Another, named Irene, had the colors purplish violet, carmine and white arranged in zones, and a third, named Favorite, rich carmine and white. If one could place one of these plants beside the original *Cineraria cruenta* of the Canary Islands, from which this garden race has descended, he could better appreciate the enormous strides that have been made in the improvement of the flower. The pure *C. cruenta*, from seed gathered in the Canaries, is in bloom just now in Kew Gardens, and the contrast of the florist's strain with it is remarkable.

One would think that a special feature would be made of forced shrubs at these early spring shows, but with the exception of a fine mass of forced white Lilac from a market florist, the old *Deutzia gracilis*, and a few specimens of *Laburnum*, and other shrubs, there was nothing remarkable in this way. The forced Lilacs were the admiration of every one, the plants being so fine and thickly hung with large dense clusters of pure white bloom. They came from Mr. Dorst, of Richmond, one of the market florists whose success in forcing Lilac is now well known. He is, in fact, one of the few florists who have proved that Lilacs can be forced profitably. Ever since October last he has sent almost daily supplies to Covent Garden. His flowers always look fresher than the imported bloom from France, and consequently fetch a higher price. The best variety he uses is Charles X., which in the ordinary flower season is purple, but when forced in the dark is pure white. Enormous quantities of Lilac plants are grown by this florist, and all are subjected to preparatory treatment in pots a year or so before wanted for forcing, so as to get them well rooted and with strong, well ripened wood. The bushes are pruned severely, leaving only the strongest growths, and then are gradually introduced into heat in batches, from October onwards. The forced supply lasts till past Easter, when it is in much demand.

W. Goldring.

London, March 22d, 1888.

Foreign Correspondence.

London Letter.

With the equinox our spring flower shows begin, the most important being that of the aristocratic Royal Botanic Society, Regents Park, on the 21st of March. This conservative body never dreams of innovation, never tolerates a change in the prize schedule, so that the masses of Hyacinths and Tulips, Azaleas and Cyclamens, repeat themselves at each spring exhibition. Nevertheless, hither throng crowds of the *élite* of London society. Forced Roses made an interesting feature, and none of the sorts shown seemed to win so many admirers as the new Lady Alice, which was even finer here than at South Kensington, and the judges awarded it a certificate of merit. The pretty little Mignonette Rose, with clusters of button-like rosettes of pale pink, was a much admired flower. It is extremely floriferous and

forcing Lilac is now well known. He is, in fact, one of the few florists who have proved that Lilacs can be forced profitably. Ever since October last he has sent almost daily supplies to Covent Garden. His flowers always look fresher than the imported bloom from France, and consequently fetch a higher price. The best variety he uses is Charles X., which in the ordinary flower season is purple, but when forced in the dark is pure white. Enormous quantities of Lilac plants are grown by this florist, and all are subjected to preparatory treatment in pots a year or so before wanted for forcing, so as to get them well rooted and with strong, well ripened wood. The bushes are pruned severely, leaving only the strongest growths, and then are gradually introduced into heat in batches, from October onwards. The forced supply lasts till past Easter, when it is in much demand.

New or Little Known Plants.

Hymenocallis humilis.*

THE so-called *Panpratium*s of the United States are represented in our illustration for this number. The true *Panpratium*s, however, are all natives of the Old World, and are characterized by having the tube of the flower considerably dilated upward, and therefore funnellform. The crown which unites the filaments is also usually lobed, and the cells of the fruit are several-seeded. The American species all belong to the genus *Hymenocallis*, which has the tube narrowly cylindrical and only two ovules in each cell of the ovary. They are found in marshes and on river banks in the southern Atlantic and Gulf States, mostly near the coast, though one species, which is supposed to be the same as the *H. rotata* of the coast, is found in Tennessee and Kentucky.

The figure here given shows one of two species which were discovered in Florida by Dr. Edward Palmer in 1874. *H. humilis* is a low and slender species, the smallest of the genus. The bulb appears to be attached to a rather thick rootstock, and sends up a few short narrow leaves and a short scape which bears a single flower. The linear segments are greenish, as are also the anthers, while the broadly funnellform truncate crown is white. The plant was found on the banks of the Indian River in flower early in March, but it has not been again collected. Dr. Palmer speaks of it as common in the grassy meadows near the river, a free bloomer, and very showy, and the most attractive plant found by him in that region. S. W.

Cultural Department.

Hybrid Aquilegias.

POSSIBLY no genus of plants more readily admits of a perfect hybridization between the different species than the *Aquilegia*. For this reason it is almost impossible to preserve the seedlings pure should the parent plant have grown near any other species. Even when separated, the pollen will be distributed through insect agency, and the new generation in almost every case will possess marked characters, differing from the species. Taking advantage of this peculiarity, hybridizers have produced some curious and beautiful strains, and the only difficulty in the way of its permanent usefulness is the trait alluded to, that of so easily departing from any fixed type.

About twenty-five years ago Dr. C. C. Parry, then engaged in studying the Flora of Colorado, happened upon *A. carulea*, Torr., and with the herbarium specimen sent the writer was a small packet of seeds which were carefully grown, and the plants served as the female parents in a remarkable series of experiments in hybridization with several other species. One of the most instructive and valuable crosses was from the pollen of the white form of *A. vulgaris*; the result being flowers identical in form with *A. carulea*, but pure snow-white in color.

In addition, as if to demonstrate the extent of its possibilities, two of the seedlings yielded perfectly double white blooms of the size and form of *A. carulea*, even retaining the peculiar long curved spurs of that species.

In the collection of seedlings were flowers of almost every imaginable tint, but all showing, in a marked degree, the influence of the *carulea* type. Subsequent efforts in the same direction with other species gave some interesting results, but none were more valuable than the above, unless we except a little bed of seedlings where the male parent was also our eastern species, *A. Canadensis*. The progeny in this case almost universally exhibited blooms showing various shades of red, but retaining all the other characters of the mother plant.

**H. HUMILIS*, Watson, *Proc. Am. Acad.*, xiv. 301. Bulb half an inch thick or more, upon a rootstock, covered by the broad sheathing bases of the leaves, which are four to six inches long by about two lines broad; scape scarcely equaling the leaves, one-flowered; segments of the spathe narrowly linear; flowers greenish, the tube fifteen lines long and shorter than the linear segments of the perianth; crown short, not narrowed at base, truncate between the erect filaments, which are a third shorter than the perianth and style; anthers greenish; ovary oblong, becoming an inch long in fruit.

Fig. 23.—*Hymenocallis humilis*.

A few showy hybrids were produced by crossing *A. formosa* and *A. chrysantha* with *A. carulea*, but the result did not prove so satisfactory as the foregoing, the colors being undecided, and the form, as a rule, greatly inferior to the parents. The development and fixing of new forms in flowers, as practiced on the numerous seed-farms in Europe, fully demonstrate, that by a systematic course of selection for a series of years, almost any peculiarity of color or form may be perpetuated from seeds and made to retain its idiosyncrasies thereafter. Whether this has been attempted with *Aquilegia* hybrids I do not know, although the numerous and very distinct colors of *A. vulgaris* will come true to name almost invariably. Division of the root was attempted and for several years the finest of these forms were retained, but finally all passed out of existence. Josiah Hoopes.

Rhus cotinoides.—Three years ago a small plant of this rare species was set in our nursery, where the ground is good and the situation well sheltered. It has grown vigorously, and made a single stemmed, well branched specimen, eight feet high. But it has been protected with barrels in winter. Last winter we gathered and tied the branches together and to a

long stake, and over these set three barrels, bottomless and headless, one on top of the other, and kept in place by being lashed between three long stout stakes. When uncovered, about the 1st of April, the branches were living to the tips, and nowhere does the tree show the least sign of injury from the winter. It has now been transplanted to a permanent position, as an isolated specimen, on the lawn, and consequently was cut in severely. It has not yet blossomed with us. But its handsome foliage and the bright red tinge of its leaf stalks and venation render it a desirable plant, even without flowers.

"It is in Alabama a small, wide branching tree, nine to ten metres in height, with a trunk sometimes 0.30 metre in diameter; on limestone benches from 700 to 900 feet elevation, in dense forests of Oak, Ash, Maple, etc.; local and very rare; not rediscovered in Arkansas or the Indian territory, in Alabama nearly exterminated."

Our specimen has been grown in an open sunny exposure and has not shown the least injury from full sunshine. W. F.

Heuchera sanguinea.—This new and handsome introduction from Mexico is likely to become the most popular of the genus as at present known. All Heucheras have elegant foliage. *H. pubescens* is generally grown for this reason alone. Last fall, with a view to increase our stock of *H. sanguinea*, which was limited to one small plant, all the crowns were cut off close to the rootstock. Placed in sand in a cool pit they rooted easily. We thus obtained a dozen plants which have bloomed persistently nearly all winter. We have also a number of seedlings, and, if we are fortunate enough to save them, in the course of time clumps in sufficient quantity can be obtained for forcing, like *Astible Japonica*, for winter blooming. The plants are in 4-inch pots, and have been grown in a night temperature of 40° to 45°. The flower stems are wiry, and self-supporting, blooming from 3 to 5 inches of their length, in a one-sided racemose cyme of red, tubular flowers of considerable substance, which have the excellent quality of being handsome in bud, and of lasting two or three weeks in a cool house. T. D. Hatfield.

Myosotis dissitiflora splendens is a variety of a very beautiful perennial Forget-me-not with flowers fully double the size of the common species (*M. palustris*). They are pink or shaded with pink when first open, but soon change into a beautiful clear blue. This plant is not quite hardy, but is well worth the protection of a cold-frame in winter. If seed is sown in June or July, the young plants will be strong enough by autumn to come through the winter safely, and can be transplanted into the open border, where they will bloom profusely during the month of May. Plants taken from the frame in February or March, and introduced into moderate heat, bloom freely in a few weeks, and a pan of this plant in flower is one of the most beautiful objects imaginable. This plant was sent to this country several years ago by Herr Leichtlin. S.

Sempervivums.—These form pretty and appropriate patches and mats about the stones in the rockery. They like an open and comparatively sunless situation, as on the northern slopes, but very much dislike to be shaded overhead by trees, shrubs or other plants. Most of the species are quite hardy. *Sempervivum globiferum*, *S. montanum*, *S. tomentosum*, *S. triste*, *S. calcareum*, *S. soboliferum*, *S. arenarium*, and some of the varieties of *S. tectorum*, are as good as any. The prettiest, perhaps, is the white cobweb *S. tomentosum*; *S. triste* is dark crimson, and *S. calcareum*—often, but erroneously, called *S. Californicum*—is a little tender. None of the Cape of Good Hope species are hardy. Now is a good time to transplant them; use the small or middle-sized heads only, as the large ones will bloom in a month or two, then die off and leave the place ragged.

"Dutch" Bulbs, such as Hyacinths, Tulips and Narcissus, that have been forced, should be stored close together in some lightly shaded place out-of-doors and kept watered so long as the leaves remain green. When the leaves die off stop watering altogether, shake out and gather the bulbs, keeping each kind by itself, and keep them in-doors till next August or September, when they may be planted thickly in rows in the garden. Next spring they may yield a few flowers, but of poor quality. The Tulips, after a few years, may recover their original strength, but the Hyacinths will only produce second-rate spikes at best. They are of no use whatever for forcing a second time.

Lilium candidum, if forced this year, should be planted out or thrown away, as to force the same bulb again next year would

be labor lost. But *L. longiflorum* and its varieties may be grown along and forced year after year and do well every season. Keep them well watered and in vigorous growth as long as the leaves stay green, then dry them off and keep them perfectly dry, but still in the earth in the pots, till next fall, when re-pot them, keeping the large bulbs in pots by themselves, and the small ones in pots by themselves, and carefully preserve every little bulblet found along the joints of the underground stems. In the *Harrisii* form most all these little bulbs, even in three or four inch pots, will bloom next spring.

Spring Flowers.—Many of our earliest flowering plants grow well in shady places. They start into growth early and bloom before the trees begin to shade them. Their growth is rapid, and before midsummer they have completed their season's work and gone to rest. Among these are Anemones, Violets, Twin-leaf, Bloodroot, Winter Aconite, Trilliums, Rue Anemones, Spring Orobolus, Pulmonaria, Lungwort, and many bulbous plants. At the same time we must bear in mind that Moss Pink, Rock Cress, Aubretia, evergreen Candytuft, and a good many others, if grown in shady places, will dwindle and die out after awhile. A safe rule to observe is, grow the short-lived deciduous kinds in shady places, and the evergreens mostly in sunny exposures.

Cutting Asparagus.—It is the practice of most gardeners to cut the large shoots of Asparagus only and leave the weaker ones to grow for the purpose of making strong roots and therefore strong shoots next year. A better custom is that adopted by Long Island gardeners, who cut everything clean every day. When the plants are all allowed to grow after the cutting season is over the strong plants assert themselves, overshadow the weaker ones and set the buds for next year's crop. This gives a larger percentage of strong buds every year. S.

Andromeda floribunda is now in good bloom. While it succeeds well in moist ground and on the north side of a wooded belt, it seems to dislike any open, sunny exposure or dry ground. *A. Japonica* is far more accommodating, but as it flowers so early, it is of little use in the North as a flowering shrub.

Pansies.—If these are to be kept in good bloom for a long time, they should be watered copiously and kept moderately thin by pulling out the poorest plants. After the middle of May a lath shading placed over, but a few feet above the beds, will help them considerably. The Bugnot, Cassier and Improved Trimardeau strains are as fine as any. H. F.

Effect of the Winter on Evergreens.

THE past winter was not unusually severe. During the summer we had abundant rain, and the ground was well soaked before frost set in; trees and shrubs made capital growth and the wood ripened up well. There was fine open working weather till the middle of December, and about the end of the month some rough cold weather. January began with wind and rain, but after New Year's, and till the middle of the month, there was fine, but somewhat cool weather; on the 16th there were 19° of frost, and from that time till the end of March we have had the most trying weather—cold, wet, stormy, changeable, icy—that I have any record of or remember. But while we had zero weather two or three nights, only once did the temperature fall as low as 3° below zero. At some one time during each of the four preceding winters the temperature has fallen to 6° below zero, but never for more than one night at a time, and usually only once, never more than twice the same season. But our trees suffer a good deal from ice storms. There is often a drizzling rain, and 6° to 10° of frost at the same time; this coats the trees completely with ice, and the branches break under the load. If a bright or warm day succeeds this icing, trees escape pretty well, but should it freeze harder, and a brisk north-west wind set in, a good deal of damage is done by the branches lashing against each other and breaking. Every succeeding year it becomes more and more apparent that in order to have the many beautiful trees and shrubs that will thrive in our climate, in perfection, we must afford them shelter. Wherever the trees have been well sheltered, there all that we would expect to be hardy have wintered well, but wherever there is insufficient shelter, there even hardy trees have suffered. It is not the intensity of the cold so much as the biting winds that injure trees and shrubs.

Pinus mitis has a yellow, unhappy look, but otherwise

the Pines are all right so far as the effects of winter are concerned.

Among Firs, *Abies grandis* has, as usual, got scorched a little; in fact, too much to allow this to be regarded as a reliable species here. One of the Oregon Douglas Firs in a more exposed place than the others has its leaves browned a very little, but not enough to hurt its wood in the least. Others of the Oregon form are not injured in the least. And the Colorado Mountain form, planted in bleak exposures enough, bear no mark of injury whatever. Nordman's, Cilician, Cephalonian, Veitch's, Spanish, and other Firs are uninjured.

No injury is observable among the Spruces. The more we know of the Colorado Blue Spruce the better it appears; its hardihood and capacity to resist severe winter winds seem to be greater than those of our White Spruce. Among Hemlock Spruces, the Japanese *Tsuga Sieboldiana*, so far as we have tried it—and there are fine large specimens here—is a hardier and more manageable tree than the common American species,

more shelter, it is unscathed. Two good sized plants of *Osmanthus illicifolius* formerly grown in tubs, wintered in a shed, and plunged outside in summer, were left out to die last fall. Not only have they survived the winter, but they never looked better than they do now, although close to them the wind scorched a Lawson's Cypress.

Scotch Broom is hurt a little. European Furze where covered with a lath shading and cedar branches is quite safe, but all the tips of the shoots that protruded beyond the protecting material, were killed. The hardy Orange tree (*Limonia trifoliata*), of which there is a small plant here, was wintered under a box filled with dry oak-leaves. It seems all right, but I think it would have been better to have omitted the leaves, as they gathered damp about it. *Phillyrea Vilmoreana* under a box covering has wintered perfectly; *Daphniphyllum glaucescens*, covered in the same way, has also kept well, but lost its upper leaves, and a large plant of *Veronica Traversii* under a box has been killed. *Berberis Japonica* under a lath shading

A Mesquite Forest in Arizona.

All the Retinosporas have wintered well, but the March blizzard spread them a good deal; *R. pisifera* and its varieties suffered most. The Golden Arbor Vitæ (*Thuja orientalis* var.) suffered in the same way. *Thuiopsis dolabrata*, in a moist, sheltered and partially shaded place, is as bright and green and healthy as it can be. Lawson's Cypress, in sheltered ground, is as healthy as any Arbor Vitæ, but wherever its head rose high enough to catch the wind, it was burned. The Sitka Cypress (*Chamaecyparis Nutkaensis*) has wintered well. This plant often behaves strangely here; sometimes one or several plants will die off unaccountably, while others growing along side of, or among them, will not betray any sign of weakness whatever. *Sequoia gigantea* and *Cryptomeria Japonica* have wintered well. All the Arbor Vitæ and Junipers are unscathed, so too are the Yews. Muslin is used to protect the Dovaston Yews, but in one instance where no protection whatever was used the plant is just as sound as those protected. A muslin protection is used around Deodars, *Podocarpus*, *Cephalotaxus*, *Cunninghamia*, and *Phorinina serrulata*, and they all have wintered perfectly—all except the Deodars, a few of the points of whose branches were hurt by rubbing against the cloth. On high, dry ground, where the wind had a sweep at it, the American Holly was browned a little; a few yards off, where a larger plant had

has wintered well. *B. Darwinii* has been killed to the ground, *B. stenophylla*, where protected by a board covering has survived, and where unprotected it has died. *Olearia Haastii*, mulched with leaves and under a lath screen, has been killed to the ground. Spanish Laurel, covered over with barrels (one above the other), has wintered fairly well—that is, the wood is all living, but the plants will lose a good many of their leaves.

Evergreen Rhododendrons never wintered better, and they are well set with flower buds, and promise a good crop of flowers. And besides the large-growing Rhododendrons, such dwarf evergreen ones as *R. ferruginum*, *ovatum*, *myrtifolium* and *Wilsonianum* have wintered well, although *R. ferruginum* has suffered somewhat. *Rhododendron punctatum* lives very well with us. *Azalea amœna* is as perfect as it can be. *Andromeda Japonica* is hardy enough, but as it blooms so early is not of much use as a flowering shrub in this climate. It is not the severity of winter, but the warm sunshine, dry atmosphere and drought of summer, that make *Andromeda floribunda*, in perfection, so great a stranger in these gardens. W. F.

Glen Cove.

"The great secret of good landscape gardening consists in the accurate preservation of the character of every scene, whether the character be originally there or created in it."—*Uvedale Price, "Essay on the Picturesque," London, 1796.*

Notes from the Arnold Arboretum.

THE Arnold Arboretum is a Museum of woody plants,—a great garden in which are being introduced, studied and arranged hardy trees and shrubs from all parts of the world; and which is to be equipped with a dendrological museum, a herbarium and a library.

The establishment is not old, but its nurseries already contain a very large collection of plants; and its influence, gained through the publications of its officers, and by its distribution of new or little known plants, is already considerable; and there is hardly an important collection of plants, in the United States or in Europe, which has not been enriched by contributions from the Arnold Arboretum. Its local influence is very considerable, and the gardens and grounds in and about Boston afford abundant proof of the interest awakened in arboriculture and of the practical advantage which a community can derive from a public establishment of this character.

The final planting of the type-collection of trees in the Arboretum has been considerably delayed by extensive and elaborate road-making, although the typical species of the most important genera, like the Pines, Larches, Spruces, Firs, Chestnuts, Oaks, Walnuts, Hickories, Beeches, Birches, Elms, Ashes, etc., are now permanently arranged and planted. The collection of hardy shrubs is extensive and important, containing about twelve hundred species and well marked varieties, among which there are very few garden hybrids or varieties. This collection is arranged in thirty-seven parallel beds each ten feet wide and two hundred and twenty-five feet long. The genera are arranged in the order adopted by Bentham and Hooker in their "*Genera Plantarum*," and the species are arranged geographically so far as it is practicable to do so, first the North American, then the European, and then the Asiatic plants. The collection is particularly rich in North American shrubs, many of which have been here first introduced into cultivation, and it contains many Chinese and Japanese plants, which, if from northern latitudes, generally do well here. Many genera are well represented; of *Rosa*, for example, there are about sixty species and many natural varieties, of *Berberis* thirty species or more, with some varieties, and of many others a proportionally large number of species.

The proper determination and labelling of the plants in the collection is a serious and difficult labor. Large numbers of plants are sent to the Arboretum every year from other botanical establishments or nurseries. Many of these plants are incorrectly named, and very often the same species or variety comes from half a dozen different places under as many names. All additions as soon as they bloom are verified or determined, and specimens prepared for the herbarium. After their identity has been settled, duplicates are removed; and the collection as it now stands is fairly well classified. Numerous additions, however, are still to be made.

It is proposed to publish in GARDEN AND FOREST, from week to week during the coming season, notes concerning such new, little known, or specially desirable plants in the collections of the Arboretum as may appear worthy of record.

Arnold Arboretum.

The Forest.

The Forest Vegetation of Northern Mexico.—III.

Prosopis juliflora, DC., Mesquit. —No tree carrying through the entire summer so much foliage has greater power to endure arid conditions than the Mesquit. (See illustration, p. 116.) Its leaflets, though numerous, are small, and are wrapped in a thick and close epidermis, which prevents rapid loss of their moisture. Hence it is to be found on the most arid tracts of sand and driest mesas of the plateau region. It is strictly a denizen of plains and valleys, never being seen amongst the growths of hills and mountains. Whilst in the rich and deep soil of the bottoms of valleys of less elevation, as those of Sonora notably, it grows to the stature of a large tree of great value, and forms the heaviest forests of such districts, in the drier situations mentioned, in order to adapt itself to the conditions of its environment, it takes the form of a shrub, widely branching beneath the soil, and rising from two to ten feet only above it. If standing amongst drifting sands, these gather in hillocks amidst such broad clumps of bushes, and heap themselves

higher year by year, as the branches push upward for light and air, until the amount of wood which forms underground in thickened branches and roots is surprisingly large. A similar accumulation of wood in the roots takes place when the Mesquit stands in the more stable soil of mesas and grassy plains, and its branches are occasionally cut away for firewood. It is the gathering of these subterranean stores of fuel that has given rise to the saying that in these regions men have to dig for their wood.

Within the State of Chihuahua it is in a few valleys only, and there growing scattered, that the Mesquit deserves the name of small tree. On the deeper bottom-lands of the Laguna country, through which runs the boundary between the States of Coahuila and Durango, it attains a trunk diameter of eight or ten inches, forms dense growths, and is exclusively cut for railroad ties. In the fertile valleys and more humid climate to the south and east of the State of Zacatecas it is a common tree, and is encouraged to grow in grain fields even, where its falling pods, in shape and size resembling those of the white field Bean, pulpy, sweet and nutritious, are harvested with care as food for man and beast. On account of its fruit the Mesquit possesses great value in the more desert districts. The pods begin to mature before the midsummer rains start the grass, and the half-famished herds are attracted to the bushes by the rich morsels they offer.

Growing with the shrubby Mesquit of the plains and valleys, itself armed at the nodes of its twigs with straight, sharp thorns an inch or more in length, are several other ligneous species of low stature nearly all abundantly furnished with thorns or hooked spines, so that passage through such growths either on foot or in the saddle is difficult and vexatious. Of most frequent occurrence, perhaps, certainly one of the most hateful, is *Celtis pallida*, Torr., which grows in broad clumps six to ten feet high, and forms, with its numerous and dense, often intricately tangled branches, impenetrable thickets. Hardly more dreadful than this or less common is *Mimosa biuncifera*, Benth., standing three to six feet high in widely branching clumps, and laying hold of one passing it with a hundred sharp and strong hooks. *Acacia Greggii*, Gray, the Cat's-claw Mesquit, here less common than the last, and but a shrub, is a similar annoyance. So, too, *Acacia Rameriana*, Schlecht, *Microrhamnus ericoides*, Gray, one to six feet high, and *Condalia spathulata*, Gray, var., six or eight feet, have exceedingly small leaves, and bear a thorn at the end of every branchlet, while *Koberlinia spinosa*, Zucc., is entirely leafless, and its branches are nothing but an aggregation of large thorns. In dry and sandy soil this plant grows but a foot or two high and spreads over broad patches; in valleys of the plateau it is commonly an erect bush; and on the low plains of Sonora I have seen it reaching a stature of fifteen or twenty feet, with a trunk diameter of six to eight inches. A Cactus, *Opuntia arborescens*, Engelm., on the plains five to ten feet high, but seen by Wislizenus in the Laguna country thirty or forty, its surface covered with myriads of needle-like spines and minute barbed points, presents, however, a climax of horrors to him who falls into its widespread arms. Amidst this chaparral the traveler acquires an instinctive dread of contact with any bush; and, if in the saddle, finds that his horse disobeys the rein that would guide him near one. C. G. Pringle.

Wood from the American White Pine, taken from old trees, is held by some authorities to be very durable because it is filled with resin. But this theory seems baseless. The heart-wood of a tree which I examined in Wisconsin contained 6.96 per cent. of solid resin in 100 parts, by weight, of absolutely dried wood substance. A Bavarian tree examined for comparison contained 6.66 per cent. The hot weather of America during the summer season may account for the small difference.

It is a well known fact that the wood of trees with very little resin, like the different species of *Juniperus*, *Sequoia*, *Cupressus* and *Taxodium*, is hardly surpassed in durability by that of any Pine-tree, which contains the highest amount of resin.

Comparing the White Pine with other European and a few American Conifers, I find the following results in regard to specific gravity and resinosity of the wood:

	Specific Gravity (Water 100.)	Per cent. of resin in 100 parts (by weight of dry wood.)
(1.) Long-leaved pine (<i>Pinus palustris</i>), sent to Europe as pitch-pine - - -	78	11.1
(2.) Larch, grown in Tyrol and known as the best and most durable of all European Conifers - - - - -	62	2.8
(3.) Wood of the same tree grown in the milder climate of the plains - - -	55	4.8
(4.) Common European pine (<i>Pinus sylvestris</i>), 113 years old - - - - -	48	5.
(5.) Common European pine (<i>Pinus sylvestris</i>), 235 years old - - - - -	47	4.9
(6.) Red pine (<i>Pinus resinosa</i>), grown in Minnesota - - - - -	41	6.
(7.) European spruce (<i>Picea excelsa</i>), - - -	41	1.6
(8.) " fir (<i>Abies pectinata</i>), - - -	39	1.
(9.) White pine (grown in America), 130 years old - - - - -	39	7.5
(10.) White pine (grown in Bavaria), 80 years old - - - - -	38	6.7

If we arrange the different trees according to the amount of resin found in their heart-wood we have the following order:

- (1.) *Pinus palustris* (as representing the section with 3 needles in one sheath).
- (2.) " *Strobus* - - - - - 5 " " "
- (3.) " *sylvestris* and *resinosa* - 2 " " "
- (4.) The Larch (representing the genus *Larix*).
- (5.) " Spruce " " " *Picea*).
- (6.) " Fir " " " *Abies*).

There cannot be the slightest doubt that the wood of the European Larch is far more durable than that of the European Pine and of the White Pine; still the amount of resin is hardly half as great in a Larch as in a Pine; even the wood of European Spruce is superior in durability to that of the White Pine. From this fact we are bound to say that the specific gravity or the substances that give to the heart-wood its color, are more important factors in determining the durability of a coniferous wood than the amount of resin. I think that the order of resinosity, viz.: *Pinus*, *Larix*, *Picea*, *Abies*, holds good not only for the European, but also for the American representatives of these genera.

H. Mayr.

Correspondence.

To the Editor of GARDEN AND FOREST:

I have been consulted recently by one of our largest dealers in flowers for an inflammation of the skin of the hands and face. The appearances which these parts presented indicated a *dermatitis venenata* of an eczematous type, and the patient expressed the opinion also that the inflammation had been caused by contact with some "poisonous" plant in his shop. He stated, moreover, that some of his assistants were affected in a similar way. The trouble manifested itself in all of them for the first time within a few weeks, and in his own case there had been three distinct recurrences of it within that period. His impression was that it had begun about the time that he had been handling large quantities of *Acacia pubescens* and *Primula obconica*, and he suspected one of these plants to be the cause of the inflammation.

I visited the shop, and found one of the salesmen presenting a similar disorder of the face and hands. The former was red, somewhat swollen, and irritable, and the latter exhibited a papular eruption. Another salesman stated that his face had been irritated, but it presented slight visible changes. There were several other employees in the establishment, whose skins were unaffected. I was told by some of them that it was a well-known trick in green-houses to shake a plant of *Acacia pubescens* over a green workman to excite an itching of the skin. *Primula obconica* was the only plant sold for the first time this season, and large quantities of this had been handled. I made a list of the plants which were then, or had been during the preceding month, for sale in the shop. They were:

- | | |
|---|--------------|
| <i>Acacia pubescens</i> . | Calceolaria. |
| Amaryllis, two varieties. | Calendula. |
| Anemone, Roman (<i>A. hortensis</i>). | Calla. |
| Azaleas. | Camellia. |
| Bouvardia. | Cineraria. |
| | Coreopsis. |

- Cyclamen.
- Cypripedium insigne*.
- " *Harrisii*.
- Cytisus.
- Daisy (*Bellis*).
- Erica.
- Ferns.
- Foliage plants.
- Freesia.
- Galax (leaves).
- Hyacinths.
- Hydrangeas.
- Jonquils.
- Lilium longiflorum*.
- " *candidum*.
- " *Harrisii*.

- Lily-of-Valley.
- Marguerite (*Chrysanthemum frutescens*).
- Mignonette.
- Narcissus.
- Nasturtium.
- Pansy.
- Pink.
- Polyanthus.
- Primulas.
- Roses.
- Smilax.
- Spiraea Japonica*.
- Tulips.
- Violets.
- Wall Flowers.

In my work on "Dermatitis Venenata," recently published, I give a list of eighty-six genera of plants, one or more species of which have been known, on good authority, to produce some degree of inflammation of the skin by contact, but in the collection above named there was but one species which finds a place in my list, viz., *Tropaolum majus*, or Garden Nasturtium. This I have known, in a few instances, to give rise to a severe inflammation of the skin of persons handling it, although it is ordinarily innocuous. It had been always handled, however, by all the persons affected in this instance with impunity. The only other plants above named, which are closely allied to species known to be "poisonous," are the Anemone, *Cypripedium* and Marguerite. Several of the Anemones, especially *A. nemorosa*, *A. patens*, and *A. hortensis*, possess irritative properties, and are even capable of vesicating the skin, but I have no knowledge of such action on the part of that in question. I know, on the authority of the late Professor Babcock, a distinguished botanist of Chicago, that our native *Cypripedium pubescens* is capable of producing as severe inflammation of the skin as *Rhus Toxicodendron*. The French Daisy, or Marguerite, is also, so far as I know, innocent, but its relationship to *Leucanthemum vulgare* and *Maruta cotula*, our White-weeds, makes it a possible object of suspicion.

There can be no doubt, in my opinion, that the cutaneous affection in these cases was of an artificial character, and that the exciting cause is to be sought among the plants recently handled in this extensive establishment. If it be some one of these lately introduced into cultivation and the public market, it is important that it should be discovered. It was suggested as a possible explanation by the proprietor, my patient, that some of the fertilizers used about low-growing plants, as Violets, etc., might have accumulated upon the leaves, and thus be transferred to the hands in making up bunches for sale, or that some of the mildews upon the foliage might, perhaps, be irritating when handled. *Ustilago hypodites*, parasitic upon *Arundo donax*, is a frequent cause of cutaneous inflammation among the workers in this Reed in France, but I am acquainted with no other fungus with such properties.

As it seems probable that the offender in this case is some new plant, I wrote to Professor Goodale asking him if he had known the suspected Acacia or Primula to cause such irritation. He replies:

"Our gardeners say that they have not experienced any trouble from *A. pubescens* or *P. obconica*, but that there is a plant, as yet undetected, which has lately given them a good deal of irritation."

It is with the hope that some cultivator of, or dealer in, flowers may be able to throw light upon the matter, that I send this communication to GARDEN AND FOREST.

Harvard Medical School, Boston.

James C. White.

To the Editor of GARDEN AND FOREST:

Sir.—You will, perhaps, be interested to hear that by far the most beautiful of the southern California shade trees is the Pepper tree. Its graceful form, delicate foliage, feathery sprays of white blossoms, and long pendant clusters of red berries, all present in profusion at every season of the year, make a most effective feature in nearly all the streets and parks of Los Angeles. Its growth is phenomenally rapid and attains great height and breadth.

The shade, though not dense, is exceedingly pleasant, not only by reason of the lovely arabesque of tracery reflected upon the hot yellow soil, but also by the pungently resinous odor which it exhales, and which is at once refreshing, stimulating and soothing to the lungs. Nature seems to have provided in great abundance this "healing balm," as the antidote for the irritating effect of the finely powdered, almost impalpable adobe dust that infests the air of California for the greater

portion of the year. The Pepper tree makes no litter of cast-off leaves, entertains no insects on trunk, branch or leaf, and its light foliage, being in constant motion, shakes off the least particle of dust; while all its neighbors are thickly coated with soil, its shining, sweetly scented boughs are always glossy green.

It grows readily from the seed, and shapes itself perfectly without the aid of the pruning hook.

R. A.

[The so-called Pepper tree (*Schinus Molle*) is a beautiful small tree, a native of Chili and some parts of Brazil, and is related to our Sumachs. It is now very generally planted in Australia, southern Europe and other warm, dry regions of the world.—ED.]

To the Editor of GARDEN AND FOREST:

Sir.—I learn from your journal that in the "Handbuch der Coniferen Benennung," *Wellingtonia* is retained as a genus for *Sequoia*. I once asked Professor Gray if, when he was in England, he called *Sequoia Wellingtonia*? "No," he replied, very earnestly. "It is too bad that a name prompted by narrow national feeling should be allowed to supersede an older botanical name." Is it too late to accomplish anything in this matter by remonstrance?

Cambridge, Mass.

Katherine Parsons.

[European botanists, of course, speak of our Big Tree as *Sequoia*, but the name *Wellingtonia* is now so universally adopted and is clung to with such tenacity, especially in Great Britain, by all nurserymen and other cultivators, that nothing short of a miracle will ever cause it to be discarded in favor of *Sequoia*.—ED.]

To the Editor of GARDEN AND FOREST:

Sir.—Your pleasant note concerning the Dog-wood with rose-colored flowers which Mark Catesby had growing in his Virginia garden a century and a half ago, reminds me of a tree in "Bear Camp," which has red flowers. Let me add that I have found in what is known as Big Gum Bottom, a new station for *Rhododendron Vascyi*. Hundreds of thousands of plants are scattered over an area of at least a square mile. They are of all sizes and are loaded with flower buds.

F. E. Boynton.

Macon Co., N. C., April 10th.

Versailles et les Trianons, par Paul Bosq. Illustré. Paris, Henri Laurens. (*Bibliothèque d'Histoire et d'Art*.)

French writers have a peculiar gift for picturesque and vivid description, as well as for recounting the facts of history with a touch so light that the record reads like a romance. Versailles and the life which there was led during the most brilliant epoch in the annals of France, offered a congenial theme to a pen of the truly Gallic sort. Monsieur Bosq has proved himself the owner of such a pen, and, moreover, has gracefully interwoven with his own words copious extracts from famous writers of earlier generations. The result is a book small in size and sparkling in tone, which, nevertheless, contains a large amount of information, and gives us a better idea of the former aspect of Versailles and of the scenes which have passed there than we could obtain by much laborious searching in a multitude of more serious-seeming volumes.

The readers of this Journal, it may be supposed, will take an especial interest in the descriptions of the great park of Versailles—the most famous park of modern times—and of the smaller ones which surround the Great and the Little Trianon. These descriptions are, of course, untechnical, but they are clear and interesting, and take us briefly through the history of the great works of which they speak. One fact which will surprise many readers is that the great park in front of the palace of Versailles was not the creation of Le Nôtre, with whose name it is so inseparably connected, but was laid out by Lemercier and planted by Boyceau during the reign of Louis XIII., and merely enlarged and remodeled by Le Nôtre when Louis XIV. made Versailles his principal residence. The first task which this monarch undertook was the remodeling of the park, and from 1664 to 1669 he occupied himself with little else. It is impossible here to repeat the account which M. Bosq gives of the work accomplished in these years; but one or two facts may be cited to give an idea of its magnitude. Nothing was left of the original design of the park except a few of the principal lines. Its borders had been extended until an English visitor could speak of it as a "province in itself." Ninety-five sculptors were employed to people it with statues. It had

fourteen hundred jets of water distributed among many fountains of immense size and lavish sculptured decoration. Trees of the largest growth had been brought in incredible numbers from various parts of Europe. Thousands of Orange trees stood in pots of costliest porcelain. The great Canal was 5.134 feet in length and 380 in breadth, and ended in a piece of water 608 feet square. Groves, trellises, "green parlors," labyrinths, and wide, formally outlined stretches of turf succeeded one another in bewildering variety and on the most colossal scale. And when the great fountains played "the whole world came to gaze." Nor when the park was finished was the work upon it done, for it was continually altered, part by part, until three almost entire reconstructions could be counted during the lifetime of Louis XIV. Under Louis XV. new and equally great changes were made, but during his later years this king abandoned the great palace and park for the Trianon; under Louis XVI. it fell into deplorable neglect, and the Revolution ruined it. Napoleon did much to restore the park, however, and between the years 1860 and 1881 it was replanted, part by part.

The palace called the Great Trianon was built, to please Madame de Montespan, upon the site of a village of that name which was razed to make room for it. Louis XIV. pulled it down and reconstructed it, and in his later years gave much attention to its magnificent gardens and took especial pleasure in nocturnal promenades in gondolas on its canal. Louis XV., taken with a sudden passing fancy for gardening, made it the scene of many agricultural and horticultural experiments; and his gardener, Claude Richard, did real service to the world by first growing in the gardens of the Great Trianon many plants which are now common all over Europe. It was he, says M. Bosq, who first cultivated what the French call "*plantes de la terre de bruyère*" and the English "American plants"—Azaleas, Rhododendrons, Andromedas, and other peat-loving plants. In 1759 Louis XV. added to his horticultural establishment a botanical garden, and placed it under the charge of Bernard de Jussieu, who pleased his master by asking nothing of him, "not even re-imbusement for his outlays."

With the *Petit Trianon* the name of Marie Antoinette is inseparably connected; and it is a name which will be long remembered by historians of the landscape gardener's art, for in her time the first "English garden" in France was laid out in this lovely spot. It is still one of the finest examples of this school of gardening in Europe, and—a fact which M. Bosq does not note—it is of especial interest to American visitors. The elder Michaux, one of the earliest systematic explorers of the Flora of America, traveled under commission from Louis XVI., and the plants he sent home as valuable novelties were cultivated in the "English garden" of the queen. Her gay existence in this garden was soon cut short in blood and fire by the Revolution, but many fine specimens of American trees still bear witness to Michaux's energy and to the fact that the most pleasure-loving monarchs may produce lasting beneficial results while striving merely to gratify their own passing tastes and fancies.

Periodical Literature.

THE February number of *Petermann's Mittheilungen* contains an interesting article by Dr. von Lendenfeld upon "The Influence of Deforesting upon the Rainfall of Australia." The author confesses that his investigations have not been carried on long enough or over a wide enough area to warrant him in claiming scientific value for his conclusions. Yet he seems to think himself justified in believing that opposite effects follow in Europe and in Australia upon the cutting off of forests. In Europe the struggle for life between different kinds of vegetation means a struggle for light; in Australia it means a struggle for moisture. The trees of Australia, having adapted themselves to the exigencies of a dry climate, send forth their roots very widely and deeply, and so wholly absorb all the moisture which exists that no grass will grow beneath them. Nor do they, like European trees, give back by evaporation a large part of what they take—as is conspicuously shown in the case of the Eucalyptus, which perpetually turns the edges of its leaves towards the sun and closes its pores during the hottest part of the day. If, says Dr. von Lendenfeld, the forests of central Europe were all destroyed, the annual rainfall would be diminished by one-quarter and vegetation in general would suffer proportionately. From this opinion many scientific observers will dissent. But whether Dr. von Lendenfeld is right or wrong in holding it, does not affect his assertion with regard to Australia—the assertion that when forests are cut there, the immediate effect is a rapid increase in the minor forms of vegetation. The roots of the trees, re-

maining in the soil, form little canals through which water penetrates the hard ground, and grass springs up and flourishes so that certain tracts in New South Wales can now support ten times as many sheep as before their trees were cut.

No less than 341 species, varieties and hybrids are included in the list of Cypripediums published in a recent issue of *Le Moniteur d'Horticulture*, and now issued as a separate publication. The parentage of hybrids is given and species with annual leaves are distinguished.

Recent Plant Portraits.

Gardener's Chronicle, March 24th.

UTRICULARIA LONGIFOLIA (showing a case of proliferation).

HOLOTHRIX LINDLEANA.

Hooker's *Icones Plantarum*.

SATYRIUM PRINCEPS, *t.* 1729; a handsome species from Port Elizabeth, with showy carmine flowers.

TABEBUIA LONGIPES, *t.* 1738.

ADINOTINUS SINENSIS, *t.* 1740; the representative of a new genus of the Honeysuckle Family, with digitate foliage of a Horse-Chestnut and the flowers of a Guelder Rose. It is from central China and should be hardy and an interesting addition to garden shrubs.

DECUMARIA SINENSIS, *t.* 1741; is also a native of central China and should make a handsome hardy garden creeper, with its obovate leaves and heads of fragrant white flowers. Much interest is attached to the plant as a second representative of a genus known heretofore only in our Southern States.

HAMAMELIS MOLLIS, *t.* 1742; a new Witch-hazel from central China.

CHRYSOSPLENIUM MACROPHYLLUM, *t.* 1744.

ABUTILON SINENSE, *t.* 1750; a native of south-west China; a shrub or low tree, with beautiful yellow flowers.

Botanical Magazine, April.

NYMPHÆA KEWENSIS, *t.* 6988; a very handsome hybrid raised in the Royal Garden in 1885 by impregnating the white flowered *N. Lotus* with the pollen of *N. Devonensis*, itself a hybrid. The flowers are described as nine inches in diameter and as remaining open for several hours after noon.

BRODLEA HOWELLII, *t.* 6989; a pretty white flowered species discovered a few years ago in Washington Territory by the collector whose name it bears.

MASDEVALLIA GIBBEROSA, *t.* 6990; a curious little species from New Grenada; of no horticultural value.

CANTLEYA LUTEA, *t.* 6991.

ABIES NORDMANNIANA, *t.* 6992; "*A. Nordmanniana* belongs to a group of five closely allied European and west Asiatic Silver Firs, the limits of which are not yet well defined. Of these the type is *A. pectinata*, the common Silver Fir, which extends from the centre of France eastward to middle Russia, and reappears in Macedonia and Greece, extending to Anatolia in the extreme east of Asia Minor, and according to Ledebour, also in the Caucasian districts of Imperetia and Ossatia. *A. Apollinis*, with its varieties *Panachaica* and *Regina Amalia*, is confined to the mountains of Greece and Macedonia. *A. Cephalonica* is more restricted still, being found only in the small island whose name it bears. Both of these last are considered as forms of *A. pectinata* by Heldreich, the most competent authority, by far, on Greek botany. *A. Cilicica* is the most Southern species, being confined to the Taurus and Anti-Taurus Mountains in ancient Cilicia, and to the Lebanon; it is the only Levantine species, and differs remarkably from the above, and from the following, in the retrorsely hooked angles of the scales. Lastly, there is *A. Nordmanniana*, to which the geographical limits assigned by Boissier are all the mountains towards the east and south-east shores of the Black Sea, including the south-western spurs of the Caucasus. . . . The nearest ally of all these species is the Afghan and Himalayan *A. Webbiana*, which approaches *A. Nordmanniana* more nearly than any of the more western species.

"*A. Nordmanniana* is a noble forest tree, attaining 150 feet in height, with a trunk six feet in diameter; it inhabits elevations of 2,000 feet and upwards, growing with species of *Corylus*, *Carpinus*, *Cornus*, *Philadelphus* and other European trees."

♂. D. Hooker.

Public Works.

Central Park, New York.—A section of the park along its Fifth Avenue boundary, and between 102d and 110th streets, originally a part of Mount St. Vincent Convent grounds, has remained undeveloped because the city did not get possession

of it at the outset. The whole district was set apart for office and nursery purposes, and the conservatory attached to the convent was allowed to stand until the buildings burned down. For twenty years the ground has been devoted to the experimental growth of plants, and a number of comparatively rare and tender trees and shrubs have been collected here in a somewhat sheltered position. The Park Board has determined to begin the permanent improvement of this area, on the recommendation of Mr. Vaux, the Landscape Architect of the Department, and Superintendent Parsons. The collection of plants that have already succeeded will be extended, and other choice trees and shrubs which will thrive in this protected amphitheatre will be added. It is fortunate for the city, and for all who appreciate thoroughly good landscape work, that Mr. Vaux is again in a position of authority in all matters which touch the design of the park.

Retail Flower Markets.

NEW YORK, *April 27th.*

The trade in flowers is very good, especially with Broadway florists. The supply is short and the average quality poor. Paul Neyron continues to hold the lead among hybrid Roses. Baroness Rothschild follows next, and then comes American Beauty. The finest of these Roses bring 75 cts. each, and the second grade cost 40 and 50 cts. Puritans are in good demand, but are scarce. They are steady at 50 cts. each. La France, Catherine Mermet and The Bride sell for \$2 a dozen. Catherine Mermets are poor in color and very ragged. There are not enough first-rate Jacqueminots to meet the request. They cost \$2.50 and \$3 a dozen. Tulips of first quality, Daffodils and Lilies-of-the-Valley bring \$1 a dozen. Lilacs are \$1 a bunch. The white variety is strong and full. Scarlet Carnations are abundant and well grown. They cost from 35 to 50 cts. a dozen. Grace Wilder and Buttercups are inferior, and may be bought for 25 cts. a dozen. Both *Lilium longiflorum* and Callas bring \$3 a dozen. Violets are small and unsatisfactory at prices unchanged. Smilax is very scarce, and in demand at 50 cts. a yard. *Asparagus tenuissimus* costs 50 and 75 cts. a yard. The filling of window-boxes and jardinières for court-yards makes busy days for gardeners. Pansies, Forget-me-nots, Daisies and Lobelias are favorite flowers for window-boxes. Vines are more used in their arrangement this spring.

PHILADELPHIA, *April 27th.*

Unusually cold weather has kept up a steady demand for all kinds of flowers of first quality, and it has also held flowers in good condition later than in ordinary seasons. Some notable weddings and dinners have helped to hold up prices by the profusion with which the finest flowers were used for decoration. These facts account for the firmness of the market, which has ranged during the week at the prices last quoted. Trailing Arbutus is very plentiful, and sells at 10 cts. to 25 cts. a bunch. This diversity of prices is not due to a difference of quality in the stock, but to the different locations where sales are made. On Tuesday an amateur in Rose culture bought all the fine Roses that were on sale and added them to his own collection for a private exhibition. His own Roses are grown in a house more than 100 feet long, specially constructed, and with every recent appliance for the most successful cultivation of Roses. Another market incident of the week was a single order for more than 1,000 heads of the beautiful pale blue Forget-me-not. This favorite is now at its best, the flowers being cut from plants that have been kept in cold-frames all winter. With warmer weather and brighter sunshine it will become seedy.

BOSTON, *April 27th.*

The supply of Roses has materially decreased during the past week, and there is now a fair demand for all good stock that is offered. One of the most popular of the new Roses, Ulrich Brüner, is seen occasionally, and it sells well. In color it is remarkably bright. Jacqueminots and Hybrids are quite scarce, good blooms of the latter selling for \$6 to \$8 per dozen. The best Jacqueminots bring \$4 per dozen. Carnations are rather small, the usual result of warmer and brighter weather. They cost about 50 cts. a dozen. Violets are scarce at \$1.50 to \$2 a hundred, and Pansies plenty at \$1 a hundred. Among the prettiest flowers seen here at this time of the year are the Primroses. These come in all shades of lemon, chrome yellow, bronze and brown. They are beautifully marked and edged, and some of the lighter colored ones are deliciously fragrant. A small bunch costs 50 cts. There is still an abundance of Lilies-of-the-Valley and Tulips, with a fair stock of Daffodils and Poet's Narcissus. One dollar a dozen is the standard price for these until they bloom out-of-doors. Lilies of all varieties are also abundant at moderate prices. Among the novelties are some white Asters which an out-of-town grower has succeeded in forcing, and a few single Sunflowers. Really good Smilax cannot be obtained at any price. Asparagus, which would make such an admirable substitute for Smilax, seems to win favor but slowly, and the only green used in large quantities is Ferns, the hardy native kinds being used for edges and background of all baskets and designs, and Maiden-hair Ferns for general finish and effect.

GARDEN AND FOREST.

The Use and Abuse of Public Pleasure Grounds.

THE daily papers of this city have recently mentioned the fact that a speculator has applied to the Park Board for permission to erect in the parks "kiosks" to contain machines "that will weigh visitors for one cent and drinking water machines that when a cent is dropped in them will deliver a glass of ice water to the thirsty." It is hardly needful to inquire whether the Board intends to give ear to this enterprising person—we think we can count with assurance upon the fact that it will make short work with his proposal. But the mere fact that such proposals can still be made in any hopeful spirit, that there are still individuals who think they can exploit our public pleasure grounds in the interests of their own pockets, calls for a word of condemnation. Of course all proposals of this sort are made solely in the hope of personal profit. It would be ridiculous to suppose that they were intended to meet any genuine public need. The public, indeed, has a right to ask that it shall be able to drink when thirsty; but if there is any park or portion of a park where this demand is not already met, it should be met by the erection of drinking fountains of proper architectural character, and no fee, however small, should be charged for their use. And although many idlers would doubtless drop their pennies in a weighing machine should they come across it in some corner of a park, the impulse which would prompt thereto is certainly not one which has a right to respectful consideration. Even if there were no other reason to object to the erection of unnecessary structures, however small, in our parks, reason enough would be found in the obligation to impress upon the less thoughtful part of the public for what purposes parks are created and in what spirit they should be enjoyed. They are not places of amusement in the sense that they should contain facilities for exciting curiosity, for spending money, or for idling away an hour in the pursuit of such gratifications as a country fair ground affords. They are places in which to seek fresh air and sunshine, healthful exercise or needed rest, and that re-

freshment of mind and body and that gratification of the sense for beauty which the contemplation of Nature affords. They are, indeed, places for recreation, but in the primitive sense of the word, not in the sense which is most commonly accepted to-day—places for the re-creation of the physical and the spiritual man. It is important that this lesson should be impressed upon the people, and there is no way of impressing it so potent as rigorously to exclude from our parks all features which tend to lead their thoughts and wishes in a wrong direction. When a park is large enough, places should, of course, be set apart for the sports and healthful out-door amusements of children and young people; buildings should be supplied in which food and drink may be had; temporary shelters should be erected in inconspicuous spots; and musical performances may very well be given from time to time—they draw the people into the park, gratify an intellectual craving, and assist the happy influence of Nature herself. But more should not be done in these directions than can be done without injuring the character of a large park as a scene of natural beauty and a place especially devoted to the enjoyment of this beauty; and nothing whatever should be done in the way of gratifying the instincts of those lounging adults who seek in a park the same sort of gratification that they seek in the street or the fair-ground. To erect in the Central Park weighing machines of any kind or drinking fountains which work by a trick, would be to run as distinctly counter to the true purposes for which it was created as to build the road for fast driving, of which there has recently been so much said. The actual injury done would, of course, not be a thousandth part as great, but the spirit in which it was done would be essentially the same. And what is true of the Central Park is just as true of all parks, no matter how small they may be or what may be the character of the population which chiefly frequents them. A weighing machine ought no more to be allowed in Tompkins Square than in the centre of the Mall.

But if the exclusion of these and all other possible devices for filling the pockets of speculators and diverting the attention of the public from the beauties of Nature, is to be recommended for the sake of the growth of the public in intelligence and appreciative power, it is just as strongly to be recommended for the sake of the beauty of our parks intrinsically considered. So many things are absolutely needed in them which disturb their repose and injure their beauty, and it is so hard to obtain these in as inoffensive a form, even, as they might be made to wear, that it is exasperating indeed to think of the possibility of their number being increased by wholly useless, worthless, profitless additions. It is hard to get even a needed drinking fountain, seat or shelter so constructed and so placed that it shall not appear a blot upon the scene. How, then, shall any one dare propose to put the hideous cast iron "kiosks" of the private speculator in a public pleasure ground, where, if allowed at all, they certainly would be put in the most conspicuous places possible—in the places where they would do the greatest possible amount of injury alike to the mood and spirit of the public and to the beauty of the park itself?

Why We Do Not Buy Growing Plants.

WE spoke recently of the difference between American dwellers in cities and those of European lands in the matter of using growing plants for the adornment of the home. As was then said, we cannot help regretting, not that so much is spent here for cut flowers, but that so little is spent for more lasting forms of beauty. There is more than one fact to be noted, however, in explanation of our seeming indifference to growing plants.

We do not mean the fact that such plants are not so freely and attractively offered for sale in our cities as they are abroad; if there were to be a demand for them a supply would no doubt be forthcoming. We mean, in the first place, the difference in certain customs of domestic life

which exist between ourselves and the French and Germans. In France and Germany women of the middle class go daily to the markets themselves, and women of the upper class send their cooks or housemaids; and neither the mistress nor the *bonne* is ashamed to be seen carrying home her big market-basket and her white-papered plant. But with us the master of the house does the marketing on his way to business; or orders are given in writing; or, if the mistress makes marketing a part of her daily shopping-task, she is neither in the dress nor the mood to carry home even the smallest flower-pot. Moreover, while abroad the *commissionnaire* stands waiting on every street-corner to take home for a few cents anything one wants to send, such transportation is much more difficult to get in American cities, and is much more expensive even if it can be obtained. Undoubtedly it is largely for these reasons that, while cut flowers are bought in such quantities on our streets by persons of moderate means, growing plants are seldom purchased by them.

But, it may be said, plants are sold abroad not only in the markets, but from house to house. In London, for example, the wagon of the flower-vender is as familiar a sight as is the wagon of the fruit-seller with us; from him flowering plants may be almost if not quite as cheaply purchased as from the market-man; and the result appears not only inside the London house, but outside. Every balcony in the long, dingy perspective of a London street is ablaze in spring and summer with Roses and Petunias, with Calceolarias and Geraniums; and the visitor thinks with dissatisfaction of the contrast presented by our own streets at the same season, when a few hotels and club-houses show laudable attempts to enliven the prospect with greenery and flowers, but when private houses are almost altogether devoid of such adornment.

Here again, however, the customs of domestic life explain the contrast, at least to some extent. The wealthy Englishman goes to town just when the wealthy American is going to the country; and he wants to make his home attractive just when the American is drawing down his blinds, boarding up his front-door, and doing his best to give the city the aspect of a plague-stricken, abandoned place. And although, naturally, the majority of people pass almost all the weeks of the year in town, whether the wealthy neighbor is at home or away, just as naturally he follows this neighbor's example. It is "the season" for all New Yorkers when it is the season for the rich to be at home; and they care most to make their homes beautiful in winter just as the middle-class Londoner cares most to make his beautiful in summer. No doubt a good deal of enthusiastic amateur gardening goes on for private gratification in the American city back-yard in summer; but to adorn the front of his home from public-spirited motives would seem to an American a futile act when there was no one in town to be gratified by it. This feeling, we allow, is natural. But, like many natural feelings, it is mistaken and unfortunate. The time when "nobody" is in town is just the time when the multitudinous individuals who are in town are in the mood to enjoy every bit of greenness, every hint and suggestion of natural beauty, which may present itself. Such individuals should then be especially bent upon doing their best to gratify each other. And the richer folk who are out of town, living in their own gardens and among great Nature's greater gardens by the seashore or upon the hills—it is surely the time when these should think a little of what they can do for human beings less favored than themselves. Few city homes are left without a care-taker in summer, and few are unvisited from time to time by the master himself. It would cost very little to fill the lower window-sills of such houses with boxes of vines and flowering plants, and it would take very little trouble to keep them fresh and brilliant all summer. And if every absent householder spent this little, how great would be the increase of pleasure for the multitudes of weary spirits to whom a week's outing must represent a summer vacation! The little money spent in this way would

be but a small mite spent on true charity as set against the great sums which the giver annually expends upon his own and his family's pleasure. And if any one doubts whether a really beautiful result can be accomplished with window-boxes filled with simple hardy plants, there are fortunately one or two New York houses to which he may look to convict him of error. Let him look, for instance, this coming summer, at the great house on the south-west corner of Madison Avenue and Thirty-eighth Street—closed and barred like its neighbors, but beautiful, and we may truly say, charitable, with wreathing vines and flowers—and, if it is what it has been in former seasons, he will be willing to make a considerable detour in his walks down-town for the delight of daily passing it.

To the Owners of Woodlands.

THE Pennsylvania Forestry Association is doing good and valuable work in teaching the people of that State to take care of their forests. *Forest Leaves*, the organ of the Association, is full of information about forests, trees and tree-culture, and with more frequent and regular publication would be a model of its kind.

The clear and forcible recommendations which this Association makes in one of its recent circulars are applicable to every owner of a forest or of a piece of woodland; and we are glad of the opportunity to reproduce them for the benefit of our readers. The Association "wants every farmer, every owner of woodland, to know—

"That his wood-lot contains a valuable crop, which it will pay him, not only to cut down and slaughter, but to manage and utilize judiciously;

"That it is possible to utilize the old trees in such a manner that a new, valuable crop is produced instead of the inferior crop, which now so often takes the place of the virgin forest after indiscriminate cutting;

"That as an intelligent manager and husbandman, he would do better to see to a natural reproduction of his wood-lot, to cut with regard to the spontaneous young growth, rather than to clear indiscriminately;

"That the time has come when forest destruction must give way to forest management; for timber is becoming more valuable every year, as it grows scarcer in the country at large;

"That in the woodlands in proper proportion lie, to a large extent, the conditions of a favorable climate and successful agriculture;

"That upon forest growth depend healthfulness and equableness of climate;

"That the forest breaks the force and tempers the fury of the northern, and cools and moistens the breath of the southern wind;

"That by its own cooler and moister atmosphere in summer and warmer atmosphere in winter, it tends to equalize temperature and humidity over the intervening fields;

"That while the open, treeless, heated prairie prevents the fall of rain, allowing moisture-laden clouds to pass over it undrained, we must thank our forest-clad hills and mountains for our more frequent, more gentle, more useful showers; and, above all,

"That the forest cover of the mountains preserves the even water flow in our springs, brooks and rivers, while its destruction, or even deterioration, increases the danger of floods, washes off the fertile soil, and then brings down unfertile soil into fertile valleys, lowers the water level, and, in general, throws out of balance the favorable conditions for agriculture;

"That while we advocate the cutting and using of the wood crop as we need it, we must not any longer, as we have done, squander and waste it; we must not clear where clearing produces danger to the surrounding country."

Leasing State Forest Lands.

THE bill empowering two of the Adirondack Commissioners to lease five-acre tracts of the State forest lands for terms of five years has been amended in the Senate to make the consent of the entire Board necessary for the confirmation of any lease. This is better, or rather it is less objectionable than the original bill; but if it is dangerous for the State to grant these unusual powers to two men, it certainly is neither safe nor wise to grant them to three men. No private individual has any claims upon the lands set apart by special enactment for public use. A refusal to give one the use of five acres for five years, or of a hundred acres for a hundred years, does not conflict with any of his rights as a citizen. A lease of any amount of this State Forest for any length of time to any person for his private use, is clearly a special privilege. If such privilege is granted to one man, another can claim it with equal force. The law will be an advertisement to every one to come and take possession of the spot that suits his particular fancy, until the people of the State will be warned off as trespassers from the most attractive portions of their own land. If the price is made low it will all be "located" in a few months. If a high price is demanded, just complaint will be made that the rich are favored as against their less prosperous neighbors.

The bill is vicious in its essence and its evils are not mitigated by any check or restraint upon what are its most dangerous tendencies. No restrictions against improper exercise of this power are provided, but the commissioners are invested with absolute powers in conveying away the State's right in its own lands. These officials are enabled, under this act, to lease and renew leases of tracts situated anywhere, to whomsoever they may elect, and upon whatever conditions they may prescribe. They are not required even to make the terms of such leases public. In short, they are released from all the restraints that experience has proved necessary for the safe administration of public trusts, so that the dangerous principle of permitting the alienation from the State of its control over its own lands is made still more dangerous in practice, by a neglect to prescribe the limitations and to set up the safeguards which ordinary prudence dictates in all cases where unusual powers are delegated to an agent.

One of the Commissioners has lately declared that he does not favor the principle of leasing, but that he wishes the right to grant leases to the two hundred persons who already have actual possession of portions of the State Forest in the North Woods and elsewhere. That is, he asks for the law to relieve himself of the trouble of deciding the question forced upon him by the presence of these squatters. The Commissioners shrink from the task of ejecting these worthy people, and they ask to be allowed therefore to confirm them in the possession of the land they have occupied because it suited them. But if they shrink from dealing with the hundreds now occupying the State Forest, they surely will be unable to stand before the thousands who will be demanding the same privilege under the new law. It is argued that the scheme can be tried a few years and if it proves unsatisfactory it can then be repealed. But if a Commission feels inadequate to treat with a few men who have possessed themselves of State land without authority, how can it hope to meet with proper spirit an army of lessees who hold the lands on a tenure legally granted by the Commission itself? Clearly such a law would add to the embarrassment of the Commission, not to speak of the increased labor it would entail and the temptations it would offer. It is a bad measure from every point of view and it should never become a law.

How the Bald Cypress Converts Lakes into Forests.

THE natural processes by which the earth we inhabit is torn down or built up are extremely interesting subjects of study. The comparative facilities for natural drainage determine more surely than any other agency

what the future condition of any territory will be. In hilly and mountainous countries the depressions would gain by surface wash what the elevations lose, but for the innumerable water courses that are continually carrying that wash to the sea. Where, however, the surface is nearly level and the water courses have but slight fall, the depressions receive nearly the entire wash occasioned by rainfall and the principal accession from the growth and decay of vegetation.

Of countries that are growing through the last named agencies no better example could be found than is furnished by the Florida peninsula. Its surface, with slight exceptions, is either level or gently undulating. The waters of Florida are clear, containing no earthy matter, and they have so slight a fall that the ocean tides affect them in places a hundred miles inland. A large portion of the rainfall, probably more than half, never reaches the running streams, but escapes by evaporation, or by percolation, to underground channels. In rainy seasons much of the country is overflowed, and in dry seasons the lakes become very shallow and the ponds dry.

A country in which there are such alternating conditions, is eminently suited to the growth of rank and diversified vegetation, both herbaceous and arborescent. In the hummocks and in the low pine woods, which are seldom visited by fire, the growth of vegetation continues almost the year round. Where such growth has progressed unchecked on uplands, the best lands for immediate cultivation are found, while the lowlands are still more valuable, if they can be drained. In the ponds a deposit of muck is being formed, which, when sufficiently elevated, will feed a different class of plants, from those that have contributed to its formation.

When we come to study this leveling process that is going on in the lowland of the South, and in Florida in particular, we are led to the conclusion that no agency has so much to do with it as the peculiar habit of growth of the Bald Cypress (*Taxodium distichum*). This tree is peculiarly adapted to the unstable soil found in ponds and alluvial river bottoms. It has a massive base, few and short branches and scanty foliage. Thus the centre of gravity is near the ground, and this, with the peculiar root growth, renders the uprooting of the tree by wind practically impossible.

The Cypress has a very broad base, which tapers rapidly into the main trunk. This is a characteristic of other trees found in like situations, notably the Tupelo (*Nyssa uniflora*), the Swamp Gum (*Nyssa aquatica*), the Swamp Ash (*Fraxinus platycarpa*), and the Swamp Privet (*Forestiera acuminata*). The Cypress is provided with additional means of maintaining its equilibrium. Where the situation favors a large growth (the Cypress sometimes measures ten feet in diameter as many feet from the ground), thin buttresses spread out from the base in all directions. This feature lends to a great Cypress swamp an almost labyrinthine appearance, especially in dry seasons, when the bases of the trees are left bare. The Cypress has also a system of strong surface roots, by the interlocking of which neighboring trees give each other support.

The surface roots of the Cypress have the peculiar habit of giving out excrescences, which rise several feet from the surface, in the form of domes, turrets and arches, or in wrapping other objects with a vine-like growth. These excrescences—commonly called knees—are hollow and of spongy texture, and their growth hastens the time when the localities they now occupy will become too elevated to suit such forms of vegetation.

In the shallow lakes and ponds that abound in the low Pine woods of the South the Cypress does most effectual work as a land builder. Germinating on a miry margin or shoal spot, in a season of low water, the young tree becomes established, sends out its raft of roots to support its spindling top, and as it grows pushes upward knees, which serve to detain floating substances and to give support to such objects as are in condition for growth. In a dry

season—which may last for a year or more—a rank growth of sub-aquatic plants springs up. This dies down in the fall and the leaves and dead twigs of the Cypress are added to the matted herbage, which each spring offers better support for a succeeding growth.

This process of vegetation progressing around a shallow lake finally converts it into a winter or dry-weather pond. During heavy falls of rain soil is washed in from the surrounding slopes. As fast as spots become unfitted for water-loving plants other species take their place. If surrounded by Pine woods seeds of lowland Pines begin to spring up nearer and nearer the centre of the pond, and the long leaved Pines make a heavy deposit on the surface each year. If near a hummock, the Bays, Magnolias, Oaks, etc., may take possession. Thus by continual wearing down and building up, through such natural agencies, there is a constant approach to uniformity of surface. A marked change must take place during a century; a still greater change during a thousand years. This process is continually going on, and the Bald Cypress has played an important part in fitting the low country of the South for man's use.

A. H. Curtiss.

April in the Pine Barrrens.

THE low Pine-barrrens of southern New Jersey are always interesting, and even at this early season there is an awakened activity in plant life that can hardly be appreciated by those dwelling a few miles to the north. By way of compensation for its lack of bold, picturesque scenery, Nature has clothed these wild levels with a charm distinctively their own, and a journey of two or three miles from home will bring me to chosen spots where such a wealth of floral treasures awaits me as can scarcely be found in any other locality of the United States.

Among our earliest treasures is the little trailing evergreen, *Pyxidantha barbata*, which often begins to open its white and rose colored flowers as early as March, while the Trailing Arbutus blooms here a month earlier than in New England. These two lovely plants frequently run together, so that it is difficult to separate them.

The Partridge-berry and the aromatic Wintergreen, with their bright red berries and evergreen leaves, also help to cover the ground and make charming masses that we covet for our gardens. But I have never succeeded in making them feel at home and happy under cultivation—which, after all, should be a matter of small regret, for they never would appear as well with civilized surroundings as they do in these lowly and lonely places.

The small shrub *Cassandra calyculata* we find in bloom near the Pyxie and the Arbutus. And a few steps beyond in the Cedar swamp, the stately *Helonias bullata* is throwing up its spikes of purplish flowers by the side of the Golden Club, while the Wind-flower is clustered thickly around an old decaying stump. What a rare gardener has been at work here! The stump itself is decorated all over with scarlet-cupped Lichens, while its decayed heart nourishes a thrifty clump of Blueberry, with pink buds just ready to burst into leaf, while beneath my feet is the lance-leaved White Violet with a delicate perfume not bestowed on our other species.

The aroma of these low woodlands in spring is delicious. The fragrance of the swaying Pines overhead, intermingled with the spicy breath of the Wax Myrtle and Sweet Fern, already waving its plummy catkins, together with odors of Sassafras and the more subtle fragrance of other shrubs, all combine to make a perfume that can only be produced in Nature's laboratory.

The deciduous trees are still leafless, and comparatively few of our plants are in bloom, yet there is an atmosphere of delicate color all about—on every twig and swelling bud, and on the lowly growth that carpets the earth. The Barrrens will be almost vivid with bright flowers by and by, but the place will hardly be more attractive than at this spring opening with its freshness, its modest beauty and its promise.

Vineland, April 20th.

Mary Treat.

The Meadows in Central Park.

SCENERY of a purely pastoral character is no doubt the most valuable element of a park within the limits of a great city like New York, for no stronger contrast to the constrained and artificial conditions of urban life can be imagined than meadow-like stretches of greensward which are not fenced in by rigid boundaries, but fade away in obscure and shadowy distance. Broad, open landscapes, with spacious skies, and the sense of enlargement and freedom which they bring, offer the most pleasing of contrasts to the hard confinement of city streets with their skyline of roofs and chimneys; the tranquillizing influence of soft, smooth, grassy surfaces is an unfailing refreshment from the wear and weariness, the strain and pressure of city life, with its strenuous effort and consuming ambition. The designers of Central Park plainly endeavored to embody, as much as possible within their limitations, and in a dignified way, without resorting to affectations or deceptions, the quiet, pastoral idea. Within the narrow area of the park the broadest scope of open meadow that could be secured was considerably less than thirty acres. But the bordering woods were so disposed as to leave the boundaries uncertain and mysterious, and the turf was made to flow into sunny alcoves and about promontories of foliage, until it was lost in hazy shadows which suggested indefinite extent of the same restful scenery. The view on page 125 is taken from a point overlooking the west meadow. The glimpse of distant turf seen under the branches of the group of trees in the centre, the opening in the wood border on the left, the skyline of trees in the distance, all suggest to the imagination a limitless extent of similar rural conditions. No object meets the eye of the observer to indicate that there is anything beyond but green pastures and tree-flecked meadows. It may be added incidentally that the illustration shows an example of exceptionally good grouping and thinning after the manner recommended by Mr. Olmsted in another column of this paper.

Foreign Correspondence.

London Letter.

LAST Tuesday the Royal Horticultural Society held its first meeting in its new quarters, and the occasion was interesting beyond expectation. The exhibition building is a stately structure, and the hall, which is of ample size, was crowded with a wonderful display. Apart from the Dutch bulbs, which by this time have become rather monotonous, noteworthy exhibits were the groups of Cyclamens, each plant carrying from sixty to eighty flowers; masses of the neat little Polyantha Roses, mentioned in a former letter; some remarkable new Tea Roses of Mr. Bennett's raising, particularly the variety called Princess of Wales, white suffused with yellow, and Lady Mary Fitzwilliam, a delicate pink. Of the numerous Orchids a plant of the famous white *Cælogyne cristata* was conspicuous for size and beauty. It measured two feet across and bore numerous long clusters of spotless flowers. This is still one of the rare and choice Orchids, and no doubt this individual plant would bring at auction from 100 to 150 guineas any day.

Among the new plants, certificates were awarded to the following:

Spathoglottis Kimballiana, named in compliment to one of your Orchid amateurs, was unquestionably the most important plant exhibited, being so very beautiful and so very distinct from all known Orchids. Its flowers may be compared with those of *Phalænopsis grandiflora* in size and form, but are of a pure canary yellow; in fact, some thought it was a yellow *Phalænopsis*. The flower is three inches in diameter, with broad sepals and petals, and its lip is adorned with a heavy blotch of rich reddish brown. The bulb is egg-shaped, and from this

proceeds the plaited or furrowed leaves about two feet long. The flower stems are from two feet to three feet high, surmounted by dense clusters of flowers, which expand in succession, two or three being open at one time. It was imported by Sander & Co., St. Albans, last year, and the description given at the sale of its rare beauty is more than confirmed by this plant, which is the first that has been seen.

Phalænopsis John Seden, a new hybrid between *P. grandiflora* and *P. Luddemanniana*, was shown for the first time by its raisers, Messrs. Veitch & Sons. This, too, is a beauty, its flowers being different from those of any other *Phalænopsis*. They are as large as those of *P. grandiflora*; the petals and sepals being pure white, copiously spotted and freckled with rosy purple, with violet and yellow on the lip. The vigorous growth of Luddemann's species is transmitted to the progeny, which is

nette was the best pink variety of this class, but the present novelty eclipses it far and away in color, being several shades darker and brighter, and the flowers are produced in larger clusters. The Polyantha Roses have been neglected, but they will fast rise in favor now that varieties are produced with rich delicate colors.

The White Lilac, Marie Lemoine, is one of the best varieties of *Syringa vulgaris* I know. The flowers shown were, of course, forced, the clusters were very large and dense, and the flowers of unusual size and snow white. It was certificated chiefly on account of its great value for forcing into early bloom, but, no doubt, it would be equally fine in the open shrubbery. The best White Lilacs we have besides this are *grandiflora alba* and *Marie Legraye*, but I think *Marie Lemoine* is finer than these even.

William Goldring.

London, March 31st.

The Meadows in Central Park.

fortunate. It is as pretty as the other new hybrid, *F. L. Ames*, and certainly is more remarkable, and if it possesses the free flowering character of *Luddemanniana*, it will make a valuable plant.

Dendrobium crassinode superbum won the unanimous approbation of the committee on account of the large size and glowing color of the flowers which thickly wreathed every stem. At first sight one would think it identical with Barber's variety, but the flowers are decidedly larger, and the bright rose-purple color, instead of being confined to the tips of the sepals and petals, runs half way down, and is in beautiful contrast with the whiteness of the other parts and the golden-blotched labellum. This makes the third variety of *D. crassinode* that has been named, the others being *Barberianum* and *album*, the latter having white petals.

Gloire de Polyantha Rose.—The charming little Polyantha Roses are now becoming better known and more popular, and this new sort, raised by Guillot of Lyons, and shown by Paul of Cheshunt, is, perhaps, the best yet produced. Until this sort came out one called *Migno-*

New or Little Known Plants.

Brodiaea Bridgesii.*

THIS is a characteristic representative of a large group of umbelliferous liliaceous plants peculiar to western North and South America, and especially abundant in California. They differ from *Allium*, a genus which is found in all northern temperate regions, and is also very abundant in the western United States, in the absence of alliaceous odor, in springing from a solid corm instead of a coated bulb, in the less spathaceous character of the bracts which subtend the umbel, and in the character of the ovary. The flowers vary greatly in color and form, being often quite handsome, and are usually jointed upon the pedicels. The most prominent genus of this group is *Brodiaea*, which includes some 20 or 25 Californian species and a number of very little known South American ones.

* B. BRIDGESII, Watson, Proc. Am. Acad. xiv. 237. Scape a foot high or more, from a small bulb; pedicels 10 to 20, elongated; perianth blue, 12 to 15 lines long, funneliform, the narrow tube exceeding the lobes; stamens 6, in one row on the throat, the short and nearly equal filaments dilated downward; anthers linear; capsule ovate, much shorter than the style.

These are variously divided into 3 or 4 sections, to which twice as many generic names have been given by different authorities, based mainly upon the form of the flower and upon differences in the stamens, three of which are sometimes reduced to broad scales, while the filaments are often winged.

The present species belongs to the section *Trititeia* or *Seubertia*, characterized by having six stamens with naked filaments and anthers suspended by the middle, and the tube of the flower narrowed downward. It is one of the most showy species of the genus, the numerous large flowers being of a bright sky-blue color. Its home is in central California among the foothills of the Sierra Nevada. Most Californian bulbs of this sort need peculiar treatment, and are apt to give poor satisfaction in eastern gardens. Some of our florists who have had experience in their culture should tell us what methods have been found to give the best results.

Cultural Department.

Calceolarias.

FROM March till May the spotted or herbaceous Calceolarias are at their best in the green-house, and they make a magnificent display. Indeed, when massed together no flowers of the season equal them in brilliancy and profusion. By continued selection in recent years larger, more perfectly formed, more brilliantly colored and distinctly spotted flowers have been produced, and the habit of the plants has become so dense and stocky that flower stems now stand erect, unsupported by any stakes.

This year we have the International strain only, and among a hundred plants now in full bloom, in one of our green-houses, there is not so much as one stick or other support of any kind among them, but they all stand bolt upright by the sturdy vigor of their own limbs.

The main points to observe in growing Calceolarias are these: Do not sow the seed before the middle of June; throughout their early life keep them as cool as possible; shade from sunshine during their whole existence, but at the same time give them as much light as possible; don't allow them to get frozen; never let them get dry at the root; don't crowd them; keep them rigidly free from aphides, and when they are in bloom do not allow water in any way, even as "dew" from an over-moist atmosphere, to touch the flowers.

Sow the seed about the 21st of June, in a seed-pan filled two-thirds deep with drainage and then to the top with fine sandy soil. Put the seed-pan in a north-facing cold-frame, with sashes on to ward off rain, and ventilate to keep it cool, and shaded to prevent the earth in the pans getting dry too quickly. The seed, although very small, has great vitality, and generally most of it germinates in a fortnight. We soon prick off the seedlings into other pans, thence into two-and-one-half-inch pots, and afterwards repot them as their size and vigor demand, till they are in six or seven-inch pots, the sizes in which they bloom.

For soil use rich, porous, turfy loam rubbed (not sifted) fine, and some dry, old manure, also some leaf soil and sharp sand, and in all cases have the pots well drained. And although the soil should be moderately firm, particularly avoid such solid potting as would be necessary for Roses or Carnations.

Throughout their whole existence Calceolarias must be copiously supplied with water at the root; and after they are in their flowering pots and well-rooted, weak manure water may be given them frequently. But as their foliage is so succulent and closely bunched together, carefully avoid wetting the leaves, else they are apt to rot off at the neck.

We keep the plants outside in the cold-frame till November, when they are brought indoors to a cool green-house and set on stages quite near the glass. While a slight frost will not hurt them, it is better not to run the risk of any freezing whatever. Throughout the winter we keep the green-house as cool as is possible with safety, never letting it fall under 35° nor

Fig. 24.—*Brodiaea Bridgesii*.

rise above 50°. In favorable weather we ventilate freely and at the same time use a little fire heat to dispel damp.

If sown early and grown along vigorously Calceolarias may be had in bloom in January, and if sown in September their flowering period can be retarded till June, but after the warm weather of summer sets in it is a difficult matter to keep them in good condition. They are at their best in April.

They are more liable to be attacked by the green fly than are any other plants in cultivation, and in order to protect them from aphides we must use tobacco vapor and smoke unsparingly, and not so much as a cure as a preventive. While the young plants are in the cold-frames, tobacco stems should be placed under and among the pots; and in the green-house tobacco stems should always be laid on the hot-water pipes under the benches. The constant vapor from these wetted stems, and thorough smoking at intervals, are the best defense against insect attacks.

Calceolaria flowers do not last long after being cut, but for a

day or two they are very good; and as they are very easily injured by crushing they must be packed and carried carefully. But the plants in bloom can be used with admirable effect in room decorations.

Glen Cove.

William Falconer.

The Rock-Garden in Spring.

Iris Korolkowi, a comparatively recent introduction from Turkestan, is one of the earliest plants in flower in a New England rock-garden. It is a dwarf, bulbous and very hardy species a span high with narrow leaves and rich purple flowers, brightly marked on the falls with large, clear yellow blotches. With it, and a little earlier, bloom *Iris reticulata* and its variety *Krelargii*, charming little Caucasian plants, also with purple yellow blotched flowers. These appear with the Crocuses and Siberian Squills in the middle of April, and nearly a fortnight later than the earliest Snowdrops. Single Hepaticas have passed when these Irises are in bloom, but some of the double flowered varieties are later and last a long time in flower. Some of these have very dark blue, and others pink or clear white flowers. Few of the earlier flowering rock-plants are more beautiful. The Spring Snowflake (*Leucoium vernum*) is one of the great attractions in the rock-garden at this time. It is a dwarf species from central Europe, hardly more than six inches high, with large, drooping, bell-shaped, fragrant flowers, an inch and a half across, when expanded, and marked with a conspicuous spot of green and yellow at the tip of each segment. This is one of the most charming of all the plants of its class. Not less attractive and equally hardy is *Chionodoxa Lucilia*—one of the handsomest and most interesting of recent additions to the perfectly hardy spring flowering bulbs. *Chionodoxa* is formed from two Greek words meaning snow and glory, and refers to the fact that this plant flowers amid the melting snows of its mountain home. It is a native of Asia Minor and Crete, and was discovered by the Swiss botanist Boissier on the western Tmolus, above Bozath, at an elevation of 7,000 over the sea level. The leaves are three to six inches long at the flowering period, strap shaped and surmounted by a slender raceme of three to six or sometimes even twenty intensely blue flowers shading to white in the centre. These are fully an inch across when expanded. *Chionodoxa Lucilia* can be as easily grown and as readily increased as a Siberian Squill or any other spring flowering bulb. A few days later *Adonis vernalis*, one of the best and hardiest of dwarf plants, opens its splendid yellow flowers, and these in turn are followed by many others, which make the rockery the most interesting spot in a garden in April and early May. These plants are all perfectly hardy, they flourish and increase and improve year after year among the rocks or in any garden border, and year after year the unfolding of their flowers is a new surprise and a new delight which old acquaintance never dulls. C.

Fruits for Market and for Home Use.

A CORRESPONDENT, after alluding to some notes of mine on fruits for home use, inquires if such fruits are not good enough for the market? This is a novel way of putting the question, and the reply might be that they are often too good. We raise home fruits to eat and market fruits to sell. Very plainly the latter must reach the market in salable condition, and they must help by their appearance to sell themselves. For home use, flavor is the highest consideration. For market, it is less important than appearance, and to have a good appearance in the market a fruit must be firm enough to endure carrying. Again, a market fruit must be productive if the grower is to make a living. From this it may be seen that while a man who makes a business of fruit-growing sends to the market every day what he would never think of putting on his own table, it does not follow that he is dishonest or wicked. He is simply driven to this by the necessities of his calling and the demands of his customers.

The Cumberland Strawberry has size, beauty, earliness and quality, all valuable features in a market berry, but no one would think of growing it for that purpose, simply because it is too tender to stand transportation. The Manchester, Downing, May King, Jewell and many others are only fitted for near markets, for the reason that they ripen soon after coloring. The Sharpless, Atlantic and Davis are good market varieties, not only on account of their size, beauty, etc., but for their firmness and ability to stand long-distance carriage. Other varieties, like the Wilson, Crescent and Jersey Queen, color in advance of maturity, and are ripe in appearance while they

are yet solid. They bear transportation for long distances, and ripen on the way to market. It is this quality that has given the Wilson such a reputation, but no one would think of growing it for family use, except those who consider one Strawberry as good as another when smothered in sugar.

The Caroline, Orange, Clarke and such tender-fleshed Raspberries are utterly unfit for market on account of their delicacy. Such fruits will only bear transportation from the garden to the table. It is only the firmer sorts of red Raspberries that will answer at all as market varieties, and a wet spell at the ripening season plays havoc with the best of these. Firmness is the redeeming quality of the Black Caps. This fits them for long carriage, and being good keepers, they are admirable for market purposes.

To illustrate the value of appearance one only need place a Dana's Hovey or Seckel Pear on sale beside a Clairgeau or Kieffer. Ninety-nine buyers would select the big, handsome fruit before the knowing hundredth man would taste the luscious little ones. And so the whole list might be canvassed. In Grapes, for example, the early and good-looking Champion always brings good prices, but it is only fit to sell.

On the other hand, it must be admitted that market-growers do wrong in sending certain varieties of Grapes as soon as they color, but long before they are really ripe. The Ives is one of the kinds that wears a color of ripeness long before it is fit to eat. The objection to the Grape is not that it is of poor quality. It is really a good Grape when ripe, but growers take advantage of its appearance to palm off an unripe, and therefore unwholesome, fruit upon the unsuspecting buyer. Here is a plain case for interference by City Boards of Health. If growers will send them, and dealers will sell them, the law should step in to protect the people from danger. Tons of these Grapes are sold in this city every year. They not only threaten the health of consumers, but they injure the business of every honest grower. E. Williams.

Globe Artichokes.—Although these are common vegetables in most good gardens in Europe, they are not in general cultivation here. There is a growing demand for them, however, not only for fashion's sake, but many people are very fond of them. Our first Artichokes are cut about the 20th or 25th of June; they are abundant through July and August, and in moderate supply till the middle of October. As a change or extra dish, they are desirable at all times, but more especially after mildew destroys Peas—about the middle of July—and until Lima Beans come in about the first of August. Our plantation is in rows some 6 feet by 4 feet apart. The plants are not quite hardy, and in November they are cut over close to the ground and the tops removed. After the first sharp frost a large armful of dry forest leaves is placed over each plant, a little thatch is scattered over the leaves to keep them in place. Early in April this covering is removed, and between the 20th and 30th of April all the living plants begin to grow. Plants required for the June and July crop should not be interfered with; but if a few old plants are lifted, and each cut into two or more parts with a sharp spade, and these divisions are planted separately, they will yield fine heads in August and September. It is also well to break up and replant the Artichokes every second year, as it keeps them in vigorous condition. We also raise a few plants from seed every year. Sown in the green-house in February or March, and grown on vigorously in hot-beds till the middle of May, and then planted out, they yield fine heads in September and October. But if sown late, or the summer is unusually cold, they will not bloom at all the first year. The seeds retain their vitality for many years. In spring, after the plantation is made up, manure and fork the ground between the plants, and, if need be, intercrop with early Spinach or Lettuces. Towards the end of June the plants will have grown so much that they will meet each other and destroy any crop that may then be between them. Summer care consists in keeping them clean and cutting off every head just as soon as it is large enough to use. This has a tendency to prolong the crop. Sometimes the young shoots of Artichokes are bleached, being treated like Cardoons, and used as a substitute for these, but this dish meets with little favor. Large Green is the variety advertised by most seedsmen. But we get a good many varieties from seed, some good and some poor, so that the best must be selected and perpetuated by division. Those that have the thickest and fleshiest scales are the most desirable.

Rhododendron Countess of Haddington.—A good specimen of this fine plant was recently exhibited at the Massachusetts Horticultural Society by Mrs. F. B. Hayes, of Lexington. It is one of the first of the long series of hybrid Rhododendrons which

have been raised by crossing Asiatic species. Its parents were *R. ciliatum* and *R. Dalhousie*. The latter is a straggling shrub six or eight feet high, growing upon trunks of trees, with immense white tubular flowers, in open terminal umbellate heads, which, with the straggling habit, this hybrid inherits. The flowers, of which there are rarely more than two or three in each umbel, are two and a half to three and a half inches long, white, tinged with pink, and in shape not unlike those of *Lilium longiflorum*. This Rhododendron, which to persons who only know our native species hardly seems to be a Rhododendron at all, is an excellent cool green-house plant, which can be had in bloom at any time from March to May. It requires the same treatment as the Indian Azaleas, and its blooming period may be retarded in the same manner. The not very good habit and its slow growth are the only drawbacks to this plant, which should be more often seen than it is in American collections. S.

nearly a quarter of an acre of ground with its numerous distinct trunks and wide spreading top, and is an object of much interest to all visitors to this remote corner of the Florida peninsula.

The Florida Wild Fig, like many other species of this genus, is parasitic. Its seed germinates upon the trunks or branches of other trees, where they are dropped by birds. The roots of the Fig, as it grows, gradually extend down and around the trunk of its host, which sooner or later inevitably perishes in their vigorous embrace, and in time reach the earth, grow together, and form the first and principal trunk of the tree. Aërial roots are constantly developed from the branches, and after becoming fixed in the soil, grow into trunks, which often exceed the original stem in size; and this tree, like many of its kindred, the Banyans

The Wild Fig Tree of Florida.

Plant Notes.

The Wild Fig Tree of Florida.

OUR illustration on this page represents, it is safe to say, one of the most remarkable individual trees which can be found within the limits of the United States. It is a specimen of the wild Florida Fig (*Ficus aurea*), which grows in what is locally known as the "hunting ground," a rich, wooded hummock on the shores of Bay Biscayne, about ten miles west of the mouth of the Miami River, in the extreme southern part of Florida. This tree covers

of the East, thus gradually extends itself over a large area.

Two species of Fig are found growing spontaneously in the semi-tropical portions of Florida. Of these, *Ficus aurea* is the most common and by far the handsomest. It grows on many of the keys from Key West to Cape Florida, and extends up the east coast to the Indian River region, but it has not been detected on any part of the west coast. There are specimens of this species in the Kew Herbarium, from the island of New Providence (Brace 356), and it is probably to be found on the other Bahama Islands.

The Florida Fig is a large evergreen, or sub-evergreen tree, with a trunk sometimes three to four feet in diameter, with

light gray, very smooth bark, and coriaceous yellow-green leaves, three to four inches long and two inches broad. They are pointed at both ends, and are borne on stout petioles, which, as well as the prominent mid-ribs, are somewhat lighter colored than the rest of the leaf. The fruit is small and nearly round, about one-third of an inch in diameter, and sessile in the axils of the leaves. It is yellow as it approaches maturity, a character which probably led Nuttall to apply the name *aurea* to this species, but when perfectly ripe turns bright red.

The noble tree which stands in front of the United States barracks at Key West, and which all visitors to the island are taken to see, belongs to this species.

Ficus aurea was quite generally introduced into cultivation a few years ago, through the agency of the Arnold Arboretum. It is easily raised from seed, and at the north makes a hardy conservatory or house plant, although inferior for this purpose to the common Rubber-plant (*Ficus elastica*).

Our picture is from a photograph made by Mr. James M. Codman, to whom the readers of this journal are indebted for many of its most interesting illustrations. C. S. S.

Notes from the Arnold Arboretum.

THE earliest shrub in flower in the collection, with the exception of a few Willows and Alders, is *Erica carnea*. It was in full bloom by the 14th of April; and the season here this year is ten or twelve days later than the average. This is a dwarf species which inhabits the lower hills of the European mountain ranges from Switzerland to the Balkans. It rarely exceeds six inches in height, although in some localities it grows erect and much taller (*E. Mediterranea*). The flowers are bright, clear red, a quarter of an inch long, drooping, axillary and arranged in leafy racemes, terminal or just below the ends of the branches. This is one of the hardiest and most satisfactory of all the Heaths in this climate; and is indispensable in a rockery. It flourishes in a compost of peat mixed with a liberal amount of sand; and blooms not only earlier in the spring than other species, but again very late in the autumn. In a milder climate it continues in flower nearly all winter. A slight protection of pine branches thrown over it in winter protects it here from the scorching sun of February and March. A variety with white flowers is generally known in gardens as *E. herbacea*.

A few days later *Daphne Mezereum* was in bloom. This is a widely distributed shrub, common over nearly the whole of Europe and Russian Asia and extending to the Arctic regions. For centuries it has been a favorite garden plant in Europe, but is now too rarely seen in this country. It is an erect glabrous shrub, one to three feet high, with rigid, erect branches, each terminated with a tuft of narrow deciduous leaves. The flowers appear before the leaves, in numerous crowded clusters of two or three, along the shoots of the preceding year, and are succeeded by large red, handsome berries. This is a very hardy and perfectly satisfactory little shrub, which thrives in any good garden-soil. There is a variety with white flowers, and another which blooms in the autumn. The bark of the *Mezereum* has medical properties, and is collected in large quantities in some parts of Germany. It is now principally employed as an ingredient in the compound decoction of Sarsaparilla.

Cornus officinalis is in full bloom at the end of the third week of April. This is a Japanese species which, according to Siebold, reaches a height of 10 to 12 feet, and is greatly valued by the Japanese as an ornamental plant and for the medicinal qualities of its bark. An admirable colored plate (*t. 50*) of this plant is published in Siebold & Zuccarini's "*Flora Japonica*." It very closely resembles the well known Cornean Cherry (*Cornus mascula*), as Siebold himself points out, and it is probably merely an extreme geographical form of that species. It has the same small yellow precocious flowers produced in simple umbels from the axils of the leaves on the shoots of the previous year, and the same cuspidate-acuminate entire leaves, which, however, in the Japanese plant have tufts of thick rusty hairs in the axils of the primary veins. The fruit, as described by Siebold, seems identical with that of the Cornean Cherry. *Cornus officinalis* is a very hardy, fast growing shrub, chiefly valuable for its very early showy inflorescence.

Cornus mascula is also in bloom, its leafless branches wreathed in yellow. But this is such a well known plant that nothing need be said about it except that it is not appreciated

or planted half often enough in this country, and that the varieties with variegated leaves—great favorites with many nurserymen—do not bear our hot sun well and are not worth planting here. Forms now exist in French collections which vary from the type very considerably in the shape and color of the fruit. The most striking and interesting of these is one with clear, bright yellow drupes.

Andromeda Japonica, an evergreen species, the Japanese representative of our Alleghany *A. floribunda*, is in flower, or rather it would have been in flower several weeks ago had not the cold, as it does every year, destroyed nearly all its beautiful racemes of pure white bell-shaped flowers. This Japanese *Andromeda* is a perfectly hardy plant, hardier here even than its American congener, but it blooms too early and is not worth cultivating at the north as a flowering plant. At the south it might be expected to open its flowers in February and to become a most useful and attractive garden ornament. *Corema Conradi*, which is now well established in the Arboretum, is also in flower. This is one of the rarest of North American shrubs, being found only in a few isolated stations on the coast of New Jersey, Long Island, New England, and in Newfoundland. It is a diffusely branched, spreading little shrub only a few inches high with scattered or nearly whorled heath-like leaves and minute apetalous flowers in small terminal heads. Its interest is botanical rather than horticultural, although the male plant is handsome when in flower with its tufted purple filaments and brown anthers. This plant is rather impatient of cultivation, but it can be grown in sandy peat in full exposure to the sun and once established it spreads rapidly. Plants, however, when they are taken up on the seashore must be thoroughly rooted in pots in a frame or cool green-house before being planted in the border. It is hopeless to try to transplant it in any other way.

The Leatherwood (*Dirca palustris*) of our far northern woods, will interest the botanist rather than the gardener accustomed only to plants with showy and conspicuous flowers. It is one of the earliest shrubs to bloom and one of the easiest to cultivate. Its small yellow flowers in dense heads appear some time before the leaves. ♀.

The Forest.

The Forests of the Yellowstone National Park.

STANDING upon one of the high peaks in the north-western part of the Yellowstone National Park, the observer looks out upon an almost unbroken, undulating, dark green forest, stretching away to the eastward and southward. This timbered area, comprising the central and southern portions of the Park, is a high, rolling, volcanic plateau, with an average altitude of about 8,000 feet, except in the extreme south, where an altitude of 10,000 feet is reached. On the north-west it is flanked by the Gallatin Range, mainly sedimentary, and along the whole eastern border by the rugged volcanic peaks of the Absaraka or Yellowstone Range, both reaching altitudes of 11,000 feet. The continental divide crosses the Park and is generally broad, ill defined and heavily timbered throughout, with an altitude varying from 8,000 to 10,000 feet.

The mountain slopes over the region, where not too precipitous and rocky, are generally well clothed with timber up to 9,000 feet. Above this the country becomes more open, grassy parks mingled with groves of trees, until the timber line is reached, which may be roughly estimated at 9,600 feet on the peaks and somewhat higher on the elevated plateaus. The altitude of the Park, with its topographic features, make it one of the storm centres of the northern Rocky Mountains. It is one of our greatest natural reservoirs, including within its limits the head waters of the Yellowstone, Gallatin, Madison and Snake Rivers. The Park lies in the Rocky Mountain belt of coniferous forests, geographically termed the Interior Pacific, and which, trending north-westward, unites in Washington Territory with that of the Pacific coast, forming a broad belt which still farther north in British America merges into the north-west extension of the Atlantic forest.

The common and most widespread tree of the Park is the Black Pine (*Pinus Murrayana*). It is the only tree forming extensive forests, to the exclusion of other species. It reaches its greatest development on the drier plateaus,

between 7,000 and 8,000 feet, here forming at least ninety per cent. of the forest. It is not generally over two feet in diameter, with a height of 60 to 100 feet, and is found from the lowest altitudes up to 9,500 feet; over the lower and drier areas with the Douglas Fir (*Pseudotsuga Douglasii*), and in higher and more moist situations—with more or less Spruce and Fir. The young forests of Black Pine are composed of slender, extremely straight trees, growing so close together as to be almost impenetrable, and are known as Lodge Pole Pines, having been so used by the Indians. Probably sixty-five per cent. of the forest area is composed of the Black Pine.

The Rocky Mountain White Pine (*Pinus flexilis*) is a common tree over the dry gravelly ridges, from 7,500 feet upward, especially above 8,000 feet, although occurring frequently at much lower elevations.

Pinus albicaulis, another White Pine, is found associated with *P. flexilis*, but ranges higher, being found scattered or in bunches on rocky exposed ridges and summits at the upper limit of tree growth, but has been observed as low as 7,500 feet. The region of the Park is probably the most eastern and southern habitat of this species. It is abundant on the higher mountains of Park, Gallatin and Madison Counties, Montana, immediately north and north-west of the Park. To an ordinary observer it closely resembles *P. flexilis* in general habit and has here been confounded with it. The whiteness of the bark, which is a characteristic farther north and north-west, is hardly noticeable here, but the brown-purple young cones which fall to pieces at maturity, at once distinguish it from *P. flexilis*, the young cones of which are green and have persistent scales. These two species form about 10 per cent. of the forest area. The Yellow Pine (*Pinus ponderosa*) might be expected on some of the lower, drier areas, as it occurs in the Black Hills on the east, and on the west in Idaho and Montana, but it has not been observed.

The Douglas or Red Fir is found up to 9,000 feet, generally scattered over the drier grass ridges and slopes. It here does not compare in size with the magnificent specimens of the Pacific coast, although some trees observed had a diameter of five feet, but generally were stunted and unsound.

The Balsam (*Abies subalpina*) ranks next to the Black Pine in numbers and distribution. It is found throughout the Park in cool, moist situations, at low elevations on the northern slopes, and especially common on wet sub-alpine slopes and plateaus about the timber line, forming groves in the Park-like openings. On moist plateaus, above 8,000 feet, and the slopes and bottoms of deep cañons, are forests of this species and of Engelmann's Spruce, these two trees forming at least twenty-five per cent. of the forest area of the Park.

The Engelmann's Spruce is generally associated with the Balsam Fir. It is the finest tree of the Park, although not comparing in size with the specimens found in the extensive forests of this species, which occur further south in the central Rocky Mountain region. Still farther north it becomes rare and of small size. The White Spruce, which occurs in the Black Hills of Dakota and in Northern Montana, reaching its greatest development in the Flathead Region, probably does not occur within the Park. Some of the cones of *Picea Engelmanni* show a transition into those of *P. alba*. This fact is suggestive, occurring, as it does, in a region between that of that greatest development of *P. Engelmanni* on the south and *P. alba* on the north; although in north-west Montana, where both species occur, Professor Sargent has observed the same fact, but they are found "at different elevations, in different soils and never mingle."

The Red Cedar is occasionally seen along the lower, drier valleys. *Juniperus communis*, var. *alpina*, occurs on rocky slopes and more frequently about the hot spring areas. On moist slopes and along streams of the lower grass areas are often found groves of the Aspen (*Populus tremuloides*). Occasionally a Cottonwood (*Popu-*

lus angustifolia) will be met with in the same situations.

The bog and stream thickets are composed of some of the following shrubs: *Betula glandulosa*, *Salix desertorum*, var. *Wolfii*; *Salix glauca*, *Alnus incana*, var. *virescens*.

Of other species may be mentioned: *Salix longifolia*, *Betula occidentalis*, *Alnus viridis*, *Prunus demissa*, *Pyrus sambucifolia*, *Amelanchier alnifolia*, *Ceanothus velutinus*, *Rhamnus alnifolia*, *Acer glabrum*.

There are some areas of considerable extent throughout the Park which are not forest covered, and at lower elevations covered with a luxuriant growth of grass and more or less of Sage Brush. These comprise, perhaps, 220 of the 3,350 square miles of the Park. Add to this about 80 square miles for all minor areas, small parks, meadows, and regions above timber line, and 180 for lakes and ponds, we have a total of 480 square miles, or about fourteen per cent. of the area of the Park. We can, therefore, safely say that about eighty-six per cent. of it is forest covered.

"Which is the Better Way?"

To the Editor of GARDEN AND FOREST:

Sir.—In a recent contribution to your columns under the above heading the opinion is expressed that in a work of landscape gardening the best results will be secured when no trees are planted but such as it is essential to its design should attain mature character. The large parks of New York and Brooklyn present the strongest possible argument for this position, and no man can realize better than I do the danger of proceeding otherwise than as thus recommended.

Yet it may be questioned whether a passage may not here and there be found in these grounds, in which a moderate amount of thinning of densely planted groups has from time to time been secured, in which more refreshment is offered to town-worn men than could have been otherwise provided. And perhaps a few words of caution to young landscape gardeners not to follow the precept too literally may serve a good purpose.

If a client asks me how the very best results are to be obtained with liberal outlay on a given piece of ground, I may say nothing to him of nurse trees, such as are to be removed as a matter of course when their purpose has been served. I may begin my answer by reminding him that though we commonly speak as if trees of the same name were of identically the same nature, they do, in fact, vary one from another as they grow up, in form, color, habit, character, constitution and in the possession of vital force, quite as much as human beings of the same surname. There is a natural proclivity with some to a quiet, regular life, with others to comparative eccentricity; with some to robust, with others to delicate habits; with some to yield to enemies, with others to fight hard with them; with some to early decay, with others to long and vigorous lives. Hence, aside from the cultural advantages for young trees of close planting, "the very best results" are likely to be attained by planting two, three or four times as many trees of those of a common name, that are to have part in a group, as it is thought will ultimately be desirable to remain in it. In this case thinning is to be made afterwards by selecting from time to time that one of the number to be taken out that appears likely to contribute least to the value of the group (regarding the group, of course, as an element of a designed more comprehensive composition). Growing in this way the single tree that may be left after many years will not be asymmetrical a "specimen" as might have resulted from the planting of one tree only of the name, but the chances are that it will be a much more desirable tree for the place in which it stands. It will be larger, stronger, more truly representative. It will have a shape more like that of a tree that has triumphed in a contest of natural selection, and a shape better expressive of its incorporation with other trees similarly grown in the group in which it was originally designed that the individuality of all its trees should at last be merged.

And the young landscape gardener should not overlook the fact that if there is a liability to the miscarriage of a design in such cases through neglect of thinning, it cannot be reckoned with certainty that a miscarriage will always be avoided by planting no tree of any kind except where a tree of that kind can with advantage stand permanently.

Ten years after a place has been planted on the latter principle no two out of a hundred of its trees may yet have begun to grow into grouping connection one with another. None will, at best, be more than promising "specimens." All will not be that, for, through ice storms, cyclonic gusts, strokes of lightning, borers, climbing boys, runaway wagons, lingering diseases or the development of a cramped or a straggling habit of growth, some will be unpromising. The place will not have upon it a hundredth part of the whole body of foliage which, with a continued flourishing condition of all its trees, is to be eventually expected, for after ten years the bulk of foliage carried by most of our trees increases annually, for many years, at a very rapidly advancing rate. In a single year the leafage of a tree, under favorable circumstances, may double. If there have been disturbing circumstances in the landscape beyond the bounds of the property, such as may be caused by a rural cemetery or a fantastic villa with flaunting flower beds and iron fountains and statuary, they will not yet have been "planted out." Under these circumstances it is not improbable that those living on the place will have become impatient of its public, unfurnished and hobbledehoy character, and to get the better of it will fill in supplementary plantings, which will be quite as unfavorable to the realization of the design of the primary planting as the neglect of proper thinnings of a dense planting would have been.

To appreciate the liability of such a result one should have in mind what great blank spaces must be left between sapling trees if it is intended to give them room for anything like their possible full development. Two continuously flourishing Elms will eventually cross branches if planted a hundred feet apart. I have paced the shadow of one of a group of Oaks at noon-day which was a hundred and forty feet across.

As a liability to the miscarriage of a design in one way or the other can by no means be fully guarded against, the conclusion seems reasonable that a landscape artist no more than any other should be asked to school himself to have only standards in view that he can be sure will be appreciated and sustained by his clients and the successors of his clients. Perhaps the better "moral" is that in planting, as in all other operations of landscape gardening, what is the best way of proceeding is a question of time, place and circumstance. There should be no stereotyped work.

The subject cannot be dismissed without another word of caution.

In contending with the superstition that prevents the due thinning of plantations, I have found that the impression had sometimes been left on the minds of the inexperienced that under no circumstances is it good practice to plant trees so that when full grown their branches are at any point likely to meet and interlock. Every one who goes to Nature for instruction knows how she laughs at such a precept. As an example, consider a very common case in any region of old farms, where trees are seen that have grown from seedlings within a space of perhaps twenty feet on each side of a former fence. In a distance of fifty yards measured along the fence line there will be numbers of large trees, the trunks of which do not stand on an average more than ten feet apart. Their roots and branches spreading outwardly from the central line, these trees have had, on the whole, no serious lack of air, light or food, and their heads have grown into an unbroken body which could have been made more beautiful, if by any course of treatment, most assuredly not either by sparser planting or more trenchant thinning.

As to shrubs, no one can have failed to notice the value in landscape of low bodies of foliage of much denser growth than it is customary to have in view in any pleasure plantations. There will have been seen, for instance, in England, neglected hedges, chiefly of Hawthorn, that, a hundred years or more after planting, have spread into masses several yards in breadth. I have come upon such close about London as well as in remote rural districts, and I have never seen anything in park or garden more beautiful. In our South-western States there are to be seen similar, but broader, and, if possible, yet more admirable bodies of Cherokee Roses, with a sprinkling of other things, that the smallest bird could not make his way through; on our northern Atlantic coast broad patches of Bayberry, with stems considerably more than a hundred to the square yard; on the high Sierras acres of the Golden Chestnut equally dense; on the top of a North Carolina mountain, half a mile square, of Catawba Rhododendron growing so closely that the ground beneath it is as bare as if it had just been plowed, harrowed and rolled. No one seeing it can be disposed to ask if it would not be better worth seeing if it had been planted more scatteringly or been thinned out as often as branches came to interlock or to be bent upward.

There are many situations where trees would shut off a prospect, in which plantations of the character thus indicated would make a much better, overlookable foreground than shrubs standing in small groups and singly upon a body of turf kept by a lawn-mower.

Brookline, 15th April, 1888.

F. L. Olmsted.

To the Editor of GARDEN AND FOREST :

Sir.—I believe in American trees for American planting, as a rule. But our Apples, Apricots, Peaches, Pears, and most of our Plums, have come from other continents. And there is a nut tree which I have seen growing on the mountain sides and plateaus of the continent of Europe, as well as in Corsica and Sardinia, which furnishes an important article of subsistence to millions of people. I refer to the so-called Spanish Chestnut. The nut is ground into flour and made into bread, and the Hon. S. S. Cox, in his recent "Search for Winter Sunbeams," declares that the mountaineers of Corsica prepare their Chestnuts for the table in twenty different ways. Our native Chestnut flourishes from New England to Georgia, but its best nuts are comparatively little things. Why can we not grow the Spanish Chestnut as well as we have grown French Pears? On Washington Heights, Manhattan Island, I have picked half a peck of these nuts that had dropped from a tree twenty years after the seed was planted, and these nuts were as good as imported ones in every way. Farther North the summers may be too short to ripen the nuts before frost, but from the latitude of New York southward we might hope for a crop as certain as from our own trees. On soils where our native Chestnut flourishes an orchard of Spanish Chestnuts would be in bearing fifteen years from seed, and the crop would be much more valuable than the wheat crop, and would increase in value for many years. In California the so-called English Walnut, the Almond, and the Olive, have been introduced with profit. Would it not be worth while to try this European Chestnut on our own coast?

East Orange, N. J.

G. B. W.

[The cultivation of the Chestnut is an important and profitable industry in most of the countries of Southern Europe, and for centuries the improvement of the fruit, through careful selection, has been going on. The wild forms of the Old World Chestnut produce fruit no larger than our American Chestnuts, although selection and cultivation has now developed varieties three or four times as large.

This fact suggests the possibility of increasing by selection and cultivation the size of the fruit of the American Chestnut, which greatly excels all European varieties in sweetness and flavor, a possibility which should attract the attention of American horticulturists, who, in the improvement of our Chestnut, have an opportunity to increase the agricultural resources and the food supply of the Atlantic States. The Spanish Chestnut has hardly been sufficiently tested yet in any part of this country to justify its general introduction as an orchard tree. It is not very hardy at the North and often suffers in severe winters; in Virginia and in the more Southern Atlantic States, however, it should succeed as well as in Northern Italy; and this tree should certainly be more generally tested there than it has been heretofore. The Japanese form of the Chestnut promises to become a valuable addition to our ornamental, and, possibly, to our orchard trees. It is hardier than the European varieties, and although the fruit is smaller, it is sweeter and better flavored. The best varieties of the Spanish Chestnut can only be propagated by grafting, as seedlings are apt to revert to the wild form. We shall be glad to learn of the experience of our readers in the Middle and Southern States with this tree.—Ed.]

Recent Publications.

The Illustrated Dictionary of Gardening; A Practical and Scientific Encyclopædia of Horticulture for Gardeners and Botanists. Edited by George Nicholson. London; and in New York by Orange Judd & Co., 1887-88.

Three volumes of this work have now appeared, and the fourth and last may be expected in a few weeks. The earliest, and still the most famous, Dictionary of Gardening, is that written by Phillip Miller. It was published in London in 1731,

and ran through eight editions. No book about plants contains quainter expression or sounder instruction and advice. George Don published in London in 1831, "A General System of Gardening and Botany," as a new edition of Miller's Dictionary, but this is a book for botanists rather than for gardeners. Johnson's "Gardener's Dictionary" followed this in England, some years later, and for a long time maintained a standard position in horticultural literature. But the great improvements that have been made in horticultural methods, and the vast numbers of new plants which gardeners are called upon to cultivate in these days, make a new general treatise upon gardening and garden plants in the English language a necessity. The work which is now before us fully supplies the need, and surpasses all its predecessors in completeness, convenience of arrangement, and in the number of its illustrations.

The arrangement is alphabetical, and it contains the Latin names of all the genera of plants found in English gardens, with a short generic description, and under each genus, in smaller type, all its species in cultivation, arranged alphabetically, each, also, with a short description, an asterisk marking those species which are especially good or distinct. English names, of which a great number are given, and Latin synonyms, are referred to the Latin name of the plants to which they belong. Much space is given to florists' flowers and horticultural varieties, some important genera, like the Rose or the Chrysanthemum, occupying many pages, with detailed illustrated descriptions of all the best varieties. Insects injurious to garden plants are figured and described; and very carefully illustrated articles are devoted to all horticultural operations, like grafting, budding and pruning. An article upon the Cucumber contains descriptions, not only of all the best varieties, but descriptions and plans of the most approved glass-houses in which to grow them. A dozen pages are devoted to the Pear, and its best varieties, and the insects which are injurious to it, and other English fruits and vegetables, are treated in the same exhaustive manner. Most useful is the information found in this book relating to the derivation of the generic names of plants—information rarely given in works on botany, and not always easy to obtain.

Any plant, no doubt, can be cultivated successfully, if study and patience enough is given to its care, but some plants are so impatient of confinement, and some are so difficult to manage, that they have little value to the ordinary gardener. Amateurs want to know the defects and drawbacks in a plant in cultivation as well as its good qualities. They always hear enough about the latter before they buy, but very little about the former. And it is in books of this character that such information would naturally be looked for; but while it contains excellent suggestions for the cultivation of an immense number of plants, little or nothing is said in these volumes about the drawbacks to any particular species or variety, an omission which those amateurs who are at the mercy of glowing nursery-catalogue descriptions, will probably often have occasion to regret.

Mr. Nicholson has been assisted by Mr. J. Garrett, who has prepared those portions of the work relating to fruit and vegetable culture, florists' flowers and general gardening work; by his associate at Kew, Mr. W. Watson, and by Professor Trail, who has written the articles on fungi, insects, and the diseases of plants. He and his associates deserve the thanks and should receive the congratulations of the horticultural world. They have produced a work which is indispensable to all persons whose studies, business or pleasure bring them in contact with garden plants.

Notes on the Bald Cypress (Taxodium distichum), by N. S. Shaler. *Memoirs of the Museum of Comparative Zoölogy*, Vol. XVI., No. 1.

The functions performed by the peculiar woody growths or "knees" which spring from the roots of our southern Cypress have never been very clearly understood, but Professor Shaler has now collected a series of facts which seem to substantiate his theory that they are in some way connected with the process of aëration of the sap. The facts are these: The knees are not developed when the trees grow on high ground. (This is still more apparent in Mexico, where the same species, probably, or a second and very closely allied species, grows only on dry ground at a considerable distance above the water-level of the streams.) They are always developed when the roots are permanently covered with water. The "knees" rise above the permanent water-level and vary in height with that level. Finally the trees die, when from any accidental cause the water rises above the tops of the "knees." These facts certainly most "incontestably show that there is some necessary connection between them and the functions of the roots when the latter are permanently submerged."

There has always been some doubt how the seed of the *Taxodium*, falling in deep water, could germinate, and yet young trees are often found in the Cypress swamps, which never become dry, growing in several feet of water. Professor Shaler is inclined to believe that such trees are not seedlings, but that they have sprung from branches, blown down from neighboring trees, which have taken root.

Retail Flower Markets.

NEW YORK, May 5th.

Business throughout the city is quiet, funeral designs and steamer baskets being all that keep it alive. The introduction of fruit into floral designs for steamer gifts interferes with the florists' revenue. Flowers have improved in quality during the week, those from bulbous plants especially being much finer as their quantity has declined. The novelty in first-class shops is Moss Roses. They cost 50 cts. a spray of one half-opened bud and one green bud. Catherine Mermet Roses are prime, and cost \$2 a dozen, as do the Bride, La France and Madame Cusin. General Jacqueminots are superb in color, and of good texture; they bring from \$2 to \$4 a dozen. There are but few Papa Gontiers arriving; these cost the same as Bon Silenes—\$1 a dozen. Perles des Jardins and Niphotos are \$1.50 a dozen. The latter are of such size and beauty that they are almost as much sought as the Bride. Puritan Roses are finer than they have been at all this season; they sell for 50 cts. each or \$5 a dozen. American Beauties bring from \$5 to \$8 a dozen. Baroness Rothschild and Mabel Morrisons run small, but are exquisite in form and color; selected blooms may be bought for \$8 a dozen. Paul Neyrons do not arrive in as good form as last week, and Ulrich Brüner shows signs of holding its petals loosely. The average price for all Hybrids may be set down as \$5 a dozen for second choice and \$8 for selected stock. Lilac is choice at \$1.50 a bunch; Mignonette is 50 cts. a bunch of twenty-five sprays. Marguerites are 20 cts., Carnations 35 cts., and Forget-me-nots are 25 cts. a dozen; Heliotrope is 50 cts. a bunch, Callas 20 cts. each, Gardenias 25 cts. each. Trailing Arbutus of delightful color and fragrance appears from Long Island and is 50 cts. a bunch. Violets grow poorer and scarcer; they are from 75 cts. to \$1.25 a bunch. Meadow Cowslips (*Calltha palustris*) from New Jersey marshes are sold in quantities on the chief thoroughfares for 5 cts. a bunch. Daffodils, Lily-of-the-Valley and Tulips cost from 75 cts. to \$1 a dozen. Smilax is somewhat more plentiful as the demand relaxes; it remains as last quoted, as does *Asparagus tenuissimus*.

PHILADELPHIA, May 5th.

Owing to the extremely warm weather, flowers were abundant everywhere early in the week. The only scarcity was of white Carnations and Lilac. It is between seasons for the last. Frequently it is in bloom here out-of-doors at this date. Last year a supply was obtained from Washington between the times when the stock for forcing was exhausted and that out-of-doors had not commenced to bloom. The warm weather also had a tendency to clobber the demand for flowers, but the returning coolness has braced up the market considerably. May usually brings a break in prices here, but this year very few flowers are blooming in the open air. Next week we may with confidence expect to report lower prices for nearly every class of flowers. Some of the dwarf Cannas are destined to be used for cut flower purposes hereafter. They are easily forced, and will add a new feature to floral decorations. Some of the spotted varieties are extremely showy, and flowering, as they do, when only two and a half to three feet high, they will not occupy much space in comparison with the older varieties. Smilax is becoming more plentiful and better in quality.

BOSTON, May 5th.

Mayflowers everywhere. The always welcome Arbutus is now in the height of its season, and its popularity. The flower stores give it the cold shoulder, but there is no scarcity on the street corners and it forms for the time being the universal corsage bouquet, while the violet quietly drops to the rear and will soon disappear for the season. There are still some violets to be had, but they are small and pinched looking. A few of the true English Violet are offered. These are only seen in the spring. The stems are too short, but the rich dark blue color and unequalled fragrance make them popular in spite of the short stems. These sell for 50 cts. a small bunch. The flower shops are filled now with grand specimens of *Hydrangea Otaksa*. Plants three feet high and three feet across sell from \$8.00 to \$12.00. With a little care their beauty will last from one to two months in an ordinary dwelling-house. Neat plants of moderate size bearing several heads of flowers, cost from \$3.00 to \$5.00 each. But few first-class Roses are seen, and they bring winter prices. The best Hybrids, such as Baroness Rothschild, Puritan and Mabel Morrison, are worth from \$6.00 to \$8.00 per dozen blooms, and American Beauty, when first-class, sells with them. Catherine Mermet, Marshall Niel and La France are worth from \$2.50 to \$4.00, according to quality. Lily-of-the-Valley is in better demand and the quality offered is uniformly good. Price, \$1.00 per dozen sprays. There are still many forced Tulips and Narcissus in the market, but a few more warm days will bring the outdoor crop in. Till then the price of these is 75 cts. to \$1.00 per dozen. Harris's Lilies on long stems are abundant and are sold as low as \$1.50 per dozen. Mignonette has become a standard flower. Sprays of the large varieties sell readily for \$1.00 per dozen. Among the novelties offered are some fine blooms of double Ranunculus.

The Improvement of School Grounds.

THE ordinary surroundings of an American public school-house are not attractive. Rarely are they shaded or turfed; more rarely is any attempt made to make the dusty ground of the traditional school-yard, or its trampled and muddy surface, even neat and pleasant to the eye. A good deal of money is generally expended in surrounding the school-lot with an imposing and generally hideous and inappropriate fence, and then the external decoration of the building is considered complete.

The discussion which this condition of things has given rise to in the columns of some of our contemporaries are suggestive of what may be accomplished in rural improvements of this character, and should bring about a much needed reform in the treatment of school-grounds throughout the country. A series of illustrations, showing a number of small country school-houses before and after the improvement of the grounds, which appeared in a recent issue of *Popular Gardening*, should be in the hands of every country school-board and every country school-teacher in the United States. Few people realize what a change in the appearance of a building the expenditure of a few dollars in planting trees and shrubs about it, and in improving the lines of its approach, can make. This these illustrations admirably show. Such simple improvements can be made to exert something more than an æsthetic and civilizing influence upon a body of school-children. They can be made to play a direct and important part in their practical instruction. The people of this country are singularly ignorant about trees, their real characters, their mode and manner of growth, their uses, and their names even. How many intelligent and well-educated men or women are there in this country who can distinguish the different Maples which they see in their daily walks, or know by sight the different Hickories, or Oaks, or Pines? Many persons who consider themselves accomplished botanists, know Ferns, and even Grasses, perhaps, or Mosses, or some of the

other lower plants, much better than they know the trees which surround them. Appreciation comes with knowledge, and until our people learn about our trees—their value, their qualities and uses, the history of their lives, their distribution and relationship to the trees of the rest of the world—they will neither really appreciate nor value them, or learn to care for and protect them. If there is ever in the United States a stable, successful and popular system of forest control and forest management, applicable alike to the forests of the State and to the humble wood-lot of the smallest farmer, it will rest upon a basis of knowledge of trees and their importance to the community, commenced in the primary schools.

If our cities and villages are ever properly adorned with well selected trees, well planted and well protected, this will be brought about through an appreciation of trees born of seed planted in country school-houses. The smallest school-grounds in the humblest community can be made to contribute to the knowledge and the subsequent love of trees. There is no school-lot so small that a place cannot be found in it for one or two trees or shrubs; and with a little care and judgment in selection, most country school-yards might contain representatives of the important trees and shrubs, and some of the lesser plants, peculiar to their immediate vicinity. Native trees should be selected for this purpose, not only because they are the best for the purpose, but because a child should first learn about the trees which he meets in his every-day life, and therefore most readily impressed upon his memory. School-yard trees should be correctly and conspicuously labeled with the English and the botanical names, in order that the name may become associated with the tree in the child's mind; and every teacher should be able to give some simple instruction, not only in regard to the characters and uses of the trees which surround the school-house, but of other trees as well.

Lessons of this simple character—object lessons in Nature—learned without an effort in early childhood, are never forgotten, and, sooner or later, bear good fruit and open the way to many delightful and lasting pleasures which most Americans are now deprived of through lack of proper early training.

School grounds in cities and large towns where land is expensive and the number of scholars large, are rarely suitable for this purpose, but the parks and squares of such cities, if properly used by teachers, can be made of much greater educational value than they are at present. Classes can always be taken into public grounds and the nature of the trees and plants which they contain explained.

That teachers and pupils alike may get the greatest advantage from the opportunities which most of our cities offer for object teaching of this nature, the trees and other important plants in public grounds should be correctly and legibly named. The whole community, and not the children and their teachers alone, derive a benefit and much real pleasure from this practice.

The trees on the Common and Public Garden in Boston have been very generally and successfully labeled; and the same thing has been attempted on a smaller scale in the Central Park in this city and in the Capitol grounds in Washington.

It might be extended with advantage to all the public grounds in the country.

Villas and Their Doorways.

WHEN the building of a detached suburban house is contemplated—whether it be a simple cottage or a more ambitious villa—the first point to be decided is, of course, the position of the house as regards distance from the street. Cases are rare in which the configuration of the ground determines this question; most often it depends merely upon the size of the lot and the taste of the owner. In former days the house was usually placed quite near the

street, such lawns and gardens as it might have lying in the rear—as we see, for instance, in the most dignified streets of Salem and of countless smaller New England towns. To-day the more usual custom is to set the house well back from the street, leaving room in front for a lawn with trees and shrubs, and in the rear for a flower or fruit garden, and often a stable. Such an arrangement, consistently followed, is certainly the best as regards the general aspect of the street, giving it width and dignity and a pleasing combination of natural with architectural features. And it is probably best, too, as regards the comfort and pleasure of the average owner; for while it removes his windows from the immediate neighborhood of the street, it permits him still to take a contemplative part in the life of the street over a foreground green and pleasant to the eye; and this privilege is more valued by the average American than, for example, by the average Englishman, while he has not the Englishman's feeling that to enjoy his own private share of Nature's beauty he must carefully seclude it from the eyes of others.

We may accept this arrangement, then, as the typical one for an American villa, and pass to the consideration of a question which deals with a matter almost as important as the position of the house itself. This is the question, Where should the main doorway of the house be placed? And it is so important because upon the answer to it will depend not only the plan of the house itself, but, to a great degree, the plan and effect of the grounds as well. From the architect's point of view it may almost always seem uncontestedly best to put the entrance in the front of the house, for, especially in small and simple buildings, he must depend upon it as one of the chief features in his design. Yet even at the sacrifice of a certain portion of architectural effect it may often be better to place it in a less conspicuous position.

A gravel or asphalt walk, intrinsically considered, is not a pleasing feature. It is simply a useful feature which should not be introduced unless necessity compels, and should always be kept as inconspicuous as convenience will allow. Whether it be straight or sinuous its action is the same—it cuts up the ground into two parts; and too much thought and skill cannot be expended in lessening the injury to unity and breadth of effect which this fact implies. If the space available for a lawn between the house and the street is narrow, it is all the greater pity to cut it up with lines of gravel; and if it is wide, then it is still a pity to sacrifice the chance for beautiful gardening effects which it affords. Place the main doorway in the front of the house, and a path must, of course, give direct access to the street; and if horses are kept, the impulse will be to make the path a driveway, although the broader the line of gravel, the more serious, of course, is the injury to the lawn. It can hardly be disputed that unless grounds are so extensive as to merit the name of a country-place rather than of villa-grounds, a driveway should never be allowed to pass through them on the side towards the street. Whether the outlook is inward from the street or outward from the windows, it will injure the effect more seriously than any other feature that is likely to be desired.

When horses are kept and a stable stands in the rear of the house, it is decidedly desirable, therefore, that the main doorway should be placed in the side of the house. Then all the drive required will be a single stretch, entering the grounds near their outermost angle and passing the door on the way to the stable. It need hardly be pointed out how much less offensive is such a drive than the one we often see even in very small grounds—cutting through their whole extent on the street side and then encircling the house to reach the stable, and often having an additional curve and an additional gateway to allow of entering and leaving the grounds without going into the stable-yard to turn.

If there is no stable, but the necessity of having a direct carriage-approach is nevertheless felt, the same arrangement commends itself, of course, for the same reasons. But

in such a case the necessity in question is much more apt to be fanciful than real. A short walk to the carriage is seldom uncomfortable, even to the feet, except in winter; and a narrow board walk temporarily laid down over the asphalt or gravel will cheaply do away with the greater part of the inconvenience that winter brings. Unless he keeps horses in a stable on the place, or unless there is an invalid in the family whose comfort must be the first consideration, an owner who cares at all for the beauty of his grounds will sacrifice his carriage-approach without a pang.

Yet even if it is sacrificed there are still good reasons why the entrance should perhaps not be in the front of the house. If it is there, we repeat, a walk is still required, and the narrowest will still be a disfigurement to the lawn—and the smaller the lawn, the greater the disfigurement. The space to be traversed from door to street will not be perceptibly lengthened by placing the door in the side of the house. No injury to the plan of the interior need result from the fact—for even if the door admits not to an old-fashioned narrow entry, but to a hall which is used as a living-room, a little ingenuity will suffice to make some of the windows of this hall command the front prospect. Again, unless the grounds are of much more than average breadth, the front of a villa is the best place for loggias or piazzas for the use of the family in summer; and such features are better adapted to their purpose when disconnected from the entrance and protected from the immediate access of visitors, while by carefully planting near the street-line and the piazza, and carefully designing the piazza itself, it will often be possible to secure a due degree of privacy as regards passers in the street.

We do not say that there may not often be good reasons for choosing the front instead of the side of a villa as the place for the main doorway when a carriage-approach thereto is not required, or that architectural effect intrinsically considered has not always a right to much attention. What we have wished to point out is that with small grounds the side of the house is decidedly the better place for the door when a carriage-approach must be combined with it, and that in all cases it will be well to consider its position carefully before the architect begins his design.

The Attack on City Hall Park.

The project to erect a huge Municipal Building in City Hall Park has been temporarily arrested by the interference of the State Legislature. Even if the new building would have any architectural merit, which is an improbable supposition, it would appear that any scheme to overshadow and belittle the old City Hall, which has a beauty of its own, not to speak of its age and associations, would find little favor. But apart from this, the project, which is by no means dead, is here spoken of as another illustration of the danger that constantly menaces parks, and every other open space, in our rapidly growing cities.

As land becomes expensive every foot not covered with brick and mortar seems wasted, and the pressure to encroach upon it, and "improve" it in some way, is almost irresistible. Here in New York, which has a smaller acreage of public ground in proportion to its size and population than any other considerable city in the civilized world, it might be supposed that a few rods of greensward and a cluster of trees would be appreciated and protected. But what was St. John's Park a few years ago has been covered up by a huge freight station. The Battery, beautiful for situation, and a priceless blessing to the thronging population about it, has been invaded by a railroad, which never rests from its effort to extend its tracks and condemn a still larger portion of it to ruin. From the City Hall Square itself a section has been already taken for Mr. Tweed's Court House and another for the Post Office, and now comes the present threat to absorb the greater fraction of what remains.

Some of the very men who are active in this project to obliterate City Hall Park, secured but a year ago the passage of an act to authorize the expenditure of a million dollars a year to construct new parks in the thickly peopled wards of the city. But if ever these new parks transform a tenement house district into an inviting neighborhood, they, in turn, must begin the same struggle for life which the older ones have been making for so many years, and with so little hope. No urban park is safe until public sentiment is educated up to a controlling belief that breathing space in a city is quite as essential to the mental, moral and physical health of its people as building space, and that the very best use to which a certain portion of its territory can be put, is to cover it with greensward and keep buildings off of it.

The *Revue Horticole* calls attention to the value of the oil yielded by the seed of the "Oil tree" of China and Japan, *Aleurites cordata*, or perhaps more correctly *Elæocca cordata*. This tree resembles in habit and in foliage the common Fig tree. The fruit is a capsule the size of an Orange, formed of several cells, each containing a large thick-shelled seed. These seeds contain an active purgative principle, and are not edible. They contain, however, forty per cent. of their weight of a clear, colorless, limpid oil, possessing remarkable siccative properties. This oil is used largely in China and Japan in the manufacture of lacquers, in making water-proof cloths, and in painting buildings and for lights. An Oil tree five or six years old may be expected, it appears, to produce an average annual crop of from 300 to 400 pounds of seed. It thrives on dry, sandy, rocky soil, and has been found to succeed in some parts of southern France, where, and in Algiers, its more general cultivation is now urged. Experiments with this tree should be made in California, and as it is found in the northern Island of Nippon, it may be expected to be hardy in many parts of the United States.

The principal flowers, especially the different varieties of Roses, in some of the florists' windows in Boston, are now conspicuously labeled. This adds much interest to these displays, and gives them a real educational value. It is a habit which might be adopted with advantage in other cities.

Tubercles on Leguminous Roots.

IT is generally believed that leguminous crops tend to increase the nitrogenous matters in the soil. It is also known that tubercles, often as large as peas and sometimes larger, are frequently formed on the roots of Beans, Peas, Clover and many other Leguminosæ, and the question has been asked whether there is any relation between the formation of the tubercles and the increased amount of nitrogen in the soil. Although the tubercles were observed long ago by Malpighi, it was not until the researches of Woronin, published in 1866, that any definite account of their structure was given. Woronin found in the cells of the Lupin-tubercles small bodies which he thought were bacteria, or something like them, and he regarded the tubercles as diseased structures. The views of Woronin were accepted at the time, but recently the subject has been studied by a number of botanists, and the results published have been so at variance with one another, that one is still perplexed to decide whether the tubercles are really the result of disease caused by some parasitic growth or whether they are normal developments of the roots.

Without speaking in detail of the many articles on the subject which have appeared within the last five years, it may be said that hardly a year ago a well known writer, in reviewing recent observations on the nature of the tubercles, stated that we could now consider it proved that the bodies which Woronin supposed to be bacteria are in fact not bacteria, but bacteroids or bodies of a nitrogenous charac-

ter which serve as reservoirs of the surplus nitrogenous material stored up by the plant. Hence, regarding the tubercles as normally produced organs loaded with albuminoids, it would be easy to understand how a soil might be enriched, as far as its nitrogenous composition is concerned, by the growth of leguminous crops.

Unfortunately, however, the question, which a year ago was supposed to be so satisfactorily settled, is now once more brought into the list of disputed questions. Prof. H. Marshall Ward, in a paper on the tubercular swellings on the roots of *Vicia Faba*, gives a clear and accurate account of the tubercles which he thinks are morbid growths and not normal reservoirs. Besides the bodies resembling bacteria, there are hyphæ or threads of a somewhat peculiar structure found passing through the cells in the interior of the tubercles, and it is his opinion that they enter the tubercles through the root-hairs on the surface. Although it is not certain how the bacteria-like bodies are formed, Prof. Ward is inclined to regard them as more like some of the yeast plants than bacteria and it may be that they are produced by budding from the tips of the hyphæ. At any rate, several facts indicate that the tubercles are not normal structures, but are produced by contagion due to germs or spores in the soil. Plants grown carefully in soils which have been heated so that all germs have been killed do not produce tubercles nor do plants grown in chemically pure fluids. Tubercles may be produced on plants grown in water-cultures by placing pieces of old tubercles on the young roots. The subject is a difficult one to study. Admitting that the origin of the bacteria-like bodies still requires investigation, it can safely be said that the tubercles are not normal structures. The peculiar threads or hyphæ can be seen by any observer, and, as they pass through from one cell to another, it is far more likely that they are parasites than that they are the cell contents modified in some way. It may be, as some have supposed, that the bacteria-like bodies have no connection with the hyphæ. That question seems to us still open, although the parasitic origin of the tubercles seems established.

W. G. Farlow.

We learn with great regret of the death of the Councillor of State, Dr. Pancic, at Belgrade, in Servia, at over seventy years of age. This distinguished scholar, who was widely esteemed, and was especially beloved for the charm of his personal qualities, devoted his life to botanical and zoölogical investigations in his native country, and achieved most noteworthy results in these lines of study. His was the enviable lot of being able to combine patriotism with science, and to develop his activity on wholly unexplored ground. His name is connected with the botanical opening of Servia, and will always be associated in the most honorable manner with the history of that country. Among the trees which he discovered it suffices to mention *Picea Omorika*, a very beautiful and characteristic species of Spruce. To the last years of his life belongs a most interesting discovery in dendrology—that of the Cherry-Laurel (*Prunus Lauro-Cerasus*),—for which Pancic first fixed a European habitat in the Servian Balkans, thereby determining for this shrub, which until then had been known only in Asia Minor, a much wider geographical range.

Botanical literature owes to Dr. Pancic a number of works, the subject of which is mainly the Flora of his native land, but which deal also, in part, with that of Bulgaria and Montenegro. Dr. Pancic lived in the most favorable circumstances. The natural science of a whole country seemed to a great extent to be embodied in him alone. He was King Milan's teacher, and enjoyed to the end of his life the entire confidence of this prince, as well as in equal degree the respect and admiration of his fellow-countrymen. He took a special interest in directing the Botanical Garden at Belgrade, which was founded but a short time ago, and is now under the practical control of a most competent young specialist, Garden-Inspector Bornmueller.

Berlin.

C. Bolle.

A Well-arranged Flower Border.

THE illustration we publish on page 137 shows another portion of the artificially formed pond, on a country place near Boston, which was pictured and described in the first number of GARDEN AND FOREST. The point to which we would now call particular attention is the flower border in the foreground, which extends much further to the spectator's left than the photographer was able to follow it, skirting the edge of the pond for a considerable distance.

In the earlier weeks of June this border offers a splendid sight and fills the air with a delicious fragrance; for then the hardy Azaleas, with which it is chiefly planted, are in bloom, showing many tints of orange, yellow, pink and white, which contrast and blend with each other in a way that might well tempt an artist's brush.* Yet this is not the only season when this border is beautiful and fragrant; for it has been planted so that a succession of flowers follow one another throughout the entire summer. Among the Azaleas hundreds of bulbs have been planted, which bloom in spring when the foliage of the Azaleas is still thin and delicate enough to permit their lowlier loveliness to appear; and the border of the pond is fringed with the great peltate California Saxifrage, the tall flower-spikes of which—two feet in height—appear in very early spring before the big, broad leaves expand. Then, rising well above the Azaleas, are groups of Lilies, pleasing to the eye in their slim, though flowerless, grace, even in the earlier weeks of summer, and ready to bring forth their flowers when the Azaleas have done blooming. The tall spikes which are conspicuous in the immediate foreground belong to the finest of our native Lilies—the Turk's Cap Lily (*Lilium superbum*). The dark clump further in the distance is a clump of the *L. umbellatum* of Japan; and the Japanese *L. lancifolium*, with its spotted blossoms, is also represented, as well as the white Japanese and the common Tiger Lily. Nor are these all the plants which mingle in this border. When the Azaleas are in bloom blue and yellow Irises are also in bloom along the water's edge; in August the delicate blossoms of the *Sabbatia* appear profusely; and in autumn days there is the Cardinal Flower and the Galtonia, with its tall spikes of white, bell-shaped, Hyacinth-like blossoms.

It is needless, we believe, to explain the superiority of planting of this sort to that most commonly seen. What is most often seen is a border filled with one kind of flower alone, or if with a succession of flowers, one that involves continual transplantings and rearrangements. But here, by a wise choice of materials, the border is enabled to take care of itself from one end of summer to the other. Here there is no need to dig up the bulbs when they have flowered, under penalty of a dreary display of withering leaves; they may be left to mature in peace against another season, the decay of their leaves being hidden by the luxuriance of the other plants. It is the same with the Lilies; and as none of the plants selected require protection in winter, the border renews its beauty summer after summer, and week by week during each summer, with but little care from man.

A word may be added with regard to the meadow that forms the distance in our picture. Its clumps of trees have been carefully arranged, but the grass is left to grow long, and, filled with Buttercups and Daisies, makes a soft and harmonious background for the brilliant border as we approach it, and is in happy contrast with the carefully kept lawns on the other side of the pond near the house.

'Laying out grounds, as it is called, may be considered as a liberal art, in some sort like poetry and painting; and its object, like that of all the liberal arts, is, or ought to be, to move the affections under the control of good sense; that is, of the best and wisest. Speaking with more precision, it is to assist Nature in moving the affections, and surely, as I have said, the affections of those who have the deepest perception of the beauty of Nature, who have the most valuable feelings—that is, the most permanent, the most independent, the most ennobling, connected with Nature and human life. No liberal art aims merely at the gratification of an individual or a class; the painter or poet is degraded in proportion as he does so; the true servants of the Arts pay homage to the human kind as impersonated in unwarped and enlightened minds. If this be so when we are merely putting together words or colors, how much more ought the feeling to prevail when we are in the midst of the realities of things; of the beauty and harmony, of the joy and happiness of living creatures; of men and

children, of birds and beasts, of hills and streams, and trees and flowers; with the changes of night and day, evening and morning, summer and winter; and all their unwearied actions and energies, as benign in the spirit that animates them, as they are beautiful and grand in that form and clothing which is given to them for the delight of our senses."

Wordsworth.—Letter to Beaumont.

Foreign Correspondence.

The Kew Arboretum.—IV.

THE genus *Quercus* is represented in the Kew Arboretum by upwards of two hundred species and named varieties. The common British Oak (*Q. pedunculata*) heads the list as far as variability is concerned, with about forty-five forms; of the other segregate of the Linnean *Q. Robur* (*Q. sessiliflora*) we have about a dozen. In a wild state the latter is much the rarer of the two, both in Britain, and, apparently, on the continent of Europe as well. Judging from the evidence afforded by trees found deep down in peat bogs, etc., in various widely separated localities, *Q. sessiliflora* was at one time a much more common tree; at present, circumstances seem to point conclusively to the fact that the species is in reality dying out. I use the word species advisedly, for the general aspect of the typical plant is so different from that of *Q. pedunculata*, that the two may be readily recognized, when growing together, even at a distance. Besides for arboricultural purposes, and to avoid too cumbersome a nomenclature, it is better to treat the two as distinct.

There are some half a hundred American Oaks—many, of course, forms which have originated under cultivation—and among them twenty-two of the species enumerated by Professor Sargent in his Catalogue of the Forest Trees of North America. Upwards of thirty hail from Asia and about seventy from Europe and North Africa. The last number of course includes the two British Oaks and their forms mentioned at the beginning of this article.

Remarkably fine examples of the Scarlet Oak (*Q. coccinea*), the Red Oak (*Q. rubra*) and the Willow Oak (*Q. Phellos*) exist in different parts of the Arboretum, but in common with all the other American biennial-fruited Oaks, few bear acorns, although the trees grow luxuriantly and are perfectly hardy. Of the Willow Oak I have never seen flowers produced at Kew; the other two whose names are above given flower annually but rarely ripen fruits; the foliage, however, as well as that of the Pin Oak (*Q. palustris*), the Yellow-barked Oak (*Q. tinctoria*), the Shingle or Laurel Oak (*Q. imbricaria*), assumes generally a brilliant color before the fall, and so enables non-traveled tree-lovers to form some idea of the brilliant effects described so enthusiastically by writers familiar with the forests of the United States. The whole group of the White Oaks is unsatisfactory at Kew, and so far as I have been able to ascertain from personal inspection, on the continent of Europe as well. Some conditions necessary for the trees are evidently lacking, for all present a stunted, unhappy aspect.

The Evergreen or Holm Oak (*Q. Ilex*), of Southern Europe, thrives well and attains a large size; during some winters huge branches are broken off by the weight of snow. The Live Oak (*Q. virens*) does not at present exist in the Kew Arboretum, and plants so named, in other English establishments which I have had an opportunity of seeing, are merely forms of the very variable *Q. Ilex*. Probably, however, the Virginian Live Oak may be growing in the Southwest of England. One of the most handsome of the European Oaks is *Q. conferta*, or, as it is usually called in gardens and nurseries, *Q. Pannonica*. This is a native of Servia, Croatia, Transylvania, etc., and in Kotschy's magnificent work, "*Die Eichen Europa's und des Orients*," he tells us that its timber is very durable, woodwork of it found in the Transylvanian mines which have not been worked since Roman times presenting the appearance, notwithstanding its great age, of newly-felled timber. In a

* An article in GARDEN AND FOREST, March 21st, 1888, speaks of the most valuable varieties of hardy Azaleas and of their needs in cultivation.

young state at any rate, the growth of *Q. conferta* is more rapid than that of our indigenous species.

For several years a specimen of the curious shrubby oak (*Q. reticulata*) from Southern Arizona and Mexico, withstood, in a somewhat sheltered spot it is true, the rigors of our English climate, but having braved the hard winter of 1879-80, it gave up the struggle to exist during the equally trying one of 1880-81. None of the characteristic Himalayan Oaks are hardy at Kew and some of the Japanese ones do not succeed. Several, however, from the latter country, do well and are perfectly hardy. *Q. acuta*—a handsome, very variable species with thick evergreen leaves—perhaps better known under the name of *Q. Buergeri*, comes under the latter category. On the other hand,

almost entirely shed as the young ones are bursting their buds—forms of the Turkey Oak (*Q. Cerris*), do wonderfully well at Kew. The Lucombe and Fulham Oaks are two of the best of these; practically they may be regarded as identical, for the differences between them are very slight. In his "*Arboreum et Frulicetum Britannicum*" Loudon says: "The age and origin of the Fulham Oak are unknown; but Mr. Smithers, an old man who has been employed in the Fulham nursery from his youth, and who remembers the tree above forty-five years, says that it always went by the name of the Fulham Oak, and that he understood it to have been raised there from seed. We have examined the tree at its collar, and down to its main roots, several feet under ground; and, from the uniform texture, and thick

A Well-arranged Flower Border.

Q. dentata of Thunberg (*Q. Daimyo* of gardens) is apt to suffer severely during an exceptionally hard winter; this species is, however, well worth a place in any collection of ornamental trees on account of its noble leaves—one I measured some four years ago, in the Isleworth Arboretum of Messrs. Charles Lee & Son being no less than eighteen inches in length, with a width, at the broadest part, of ten inches. *Q. dentata* is also especially interesting by reason of its being one of the food plants of a Chinese silkworm, a long account of which is contained in the "Commercial Reports from Her Majesty's Consuls in China and Japan, 1865."

The evergreen, or rather sub-evergreen—for the old leaves, although remaining on the tree throughout the winter, are

corky character of the bark, we feel satisfied that it is not a grafted tree." A few years ago, however, before Messrs. Osborne's nursery was broken up, I saw this same tree, and shoots of *Quercus pedunculata* were springing from the trunk, proving that the specimen was a grafted one and that in spite of his careful examination Loudon was deceived. Another Oak, figured and described by Dr. Masters in the *Gardeners' Chronicle*, series ii., vol. xiv. p. 715, under the name of *Q. glandulifera* of Blume, is, I have little doubt, a curious hybrid of which the Turkey Oak is one of the parents. At any rate, it is not the typical Japanese plant described originally under the name of *Q. glandulifera* by Blume.

George Nicholson.

London Letter.

CAMELIAS are backward this season, but among those now in full beauty at Veitch's nurseries none can eclipse the variety C. M. Hovey, for which, I believe, we are indebted to one of your Boston nurserymen. The perfect form of the flower, its charming, soft, rosy carmine color and large size make it one of the most admired of Camellias, and of its color it is peerless. Camellias are not so popular here as they were formerly, because they have been supplanted by Roses since the early forcing of these flowers has become so well understood. People like the exquisite, if somewhat stiff and artificial, form of double Camellias, and are delighted with their soft colors, but lacking perfume, they can never rival the Rose. In Paul's nurseries at Waltham Cross, where, of course, the Rose reigns supreme, there is one of the finest collections of Camellias in this country. A lofty and spacious house 100 feet long is devoted entirely to the huge specimens which make at this season a magnificent display. On going through the house the other day I jotted down a few of the sorts which to me were most conspicuous and the most beautiful. Of whites none was superior to old Double White. More of this old sort are grown and more sold than of any other, it being indispensable in every green-house. Another good white is Ninfa Egeria, more floriferous than Alba plena, and not so large, but quite as double. Innocenza fimbriata and Alba elegantissima are likewise very fine white. The more brilliant colors (crimson and reds) are best represented by Imbricata Mathotiana, Manara, Benneyi Coquettina and Auguste Delfosse. The lovely pinks and delicate rose tints are favorites with every one, and I singled out Marchioness of Exeter, L'Avenir, Principessa Aldobrandini and Lady Hume's Blush as the finest then in bloom. There were numbers of sorts with striped and flaked petals; but as I am not an admirer of such bizarre flowers, I did not stop to take their names. The foregoing sorts named are undoubtedly the pick in their respective colors out of a collection numbering some hundreds of sorts: I have no doubt but that the Camellia with you is as much appreciated as here, and certainly there is no finer evergreen shrub for planting out in a green-house for cutting from.

Orchids are here becoming so popular that some amateurs have begun to make specialties of certain genera of the family. The Cyripediums are for the moment the popular favorites, and many growers keep scarcely any other kind, and devote several large houses exclusively to them. Now that its hybrids have become so numerous, an amateur may spend a small fortune in acquiring a full collection of this genus alone. The quaint form of the flowers of all the Lady's Slipper Orchids, their subtle, though quiet coloring, together with their evergreen foliage, which is often very handsomely marked, combine to render them highly popular. I have seen advance proofs of a new illustrated work on the genus Cyripedium, which will be issued shortly by M. Godefroy-Lebeuf, of Argen-teuil, France. The colored plates are splendid examples of the chromo-lithographer's art, and the letter-press is written by Mr. N. E. Brown, of the Royal Herbarium, Kew, who has made a special study of the genus. The text will be rendered in Latin, French and English, so that altogether it will be the finest monograph of Cyripedium that has yet been issued. During the last ten years wonderful strides have been made in hybridizing Orchids, and especially Cyripediums, which seem to lend themselves to the process with exceptional facility; but while there are numbers of really magnificent hybrids, it must also be mentioned that many of them are worthless as ornamental plants, and in not a few instances they are ugly. The wonderful new *C. Rothschildianum*, which Messrs. Sander have quite recently imported, is making a great stir. It is described as eclipsing the handsome *C. Stonei*, but as I have not yet seen it I shall reserve my opinion.

London, April 5th.

New or Little Known Plants.

Hymenocallis Palmeri.*

THIS second species of *Hymenocallis* from Florida was found by Dr. Palmer in the neighborhood of Biscayan Bay in the extreme southern part of the State. In its general character it is much like the *H. humilis* already

*H. PALMERI, Watson, *Proc. Am. Acad.*, xiv. 301. Bulb small, narrowly oblong, with thick roots; leaves with short sheaths, a foot long by three lines wide or less; scape nearly as high, one-flowered, the segments of the spathe very narrow; perianth white, the tube about equaling the segments, which are three and one-half or four inches long by a line wide; crown fifteen lines deep, acuminate lobed between the erect filaments; anthers greenish; ovary oblong-ovate.

figured, but is taller and larger flowered. The bulb is smaller, with thick roots, and the leaves and slender scape are nearly a foot high. The tube and the very narrow segments of the perianth of the solitary white flower are each three or four inches long, and the border of the deep funnelliform crown is acuminate lobed between the filaments. It was found growing in sandy soil in low grassy bottoms near the beach, blooming in May.

The marshes and river banks of Florida doubtless yet hold many novelties to repay the search of the observant explorer of the plant life of that State. These species of *Hymenocallis*, the *Nymphaea flava* and the *Zephyranthes Treatii* are specimens of what may still be expected. The Orchids also, the Palms, and the Tillandsias of the forests are by no means well known, and it may be said with truth that while exploration there may be attended with its difficulties, there is probably no part of our country that gives better promise of reward in the way of new and interesting species.

S. W.

Plant Notes.

Rocky Mountain Cyripediums.

UNDER *Cyripedium fasciculatum*, in a late number, the general statement was made that "none of these [the eastern species] range as far west as the Rocky Mountains, . . . within the limits of the United States." This was intended to express our present knowledge of the range of the species. In British America the species with a small yellow sac, *C. parviflorum*, extends through the Saskatchewan region to Manitoba and into the mountains. It may possibly enter north-western Montana and have been confounded with the western *C. montanum*, the only very obvious difference between the species being the color of the lip, which cannot always be determined in dried specimens. That region, drained by Clark's Fork, is the extreme eastern limit of the Pacific flora, and *C. montanum* is found there. But *C. parviflorum* has not certainly been found in the mountains south of the boundary, so far as I know. The larger flowered yellow species, *C. pubescens*, is known to occur in north-eastern Colorado, in the valley of the Platte, at least, and probably within the mountains, and this much of exception should have been made to the above statement.

It appears now that a still more decided exception must be made, as a note has just been received from Mr. W. F. Flint, of Winchester, N. H., giving an interesting account of his having found in 1878 a *Cyripedium*, which he took to be *C. parviflorum*, in the Uncompahgre valley in south-western Colorado. This is upon the western side of the Continental Divide, as the waters of the Uncompahgre find their way into the Colorado River. These *Cyripediums* were growing in considerable numbers upon the river bank about a quarter of a mile north of the Los Pinos Agency buildings. Unfortunately, no specimens were preserved, and as the valley is now occupied by white settlers, this particular locality for the plant may be destroyed. But it must occur elsewhere in that region, and it is hoped that specimens will yet come to hand for its more definite determination.

S. W.

Merendera Caucasia, var. *Ruthenica*.—This is one of our newer and most beautiful spring-flowering bulbs, and deserves to be largely grown. It is a native of Transylvania, very hardy and comes very early into flower, blooming, according to climate, from the middle of February to the end of March. The flowers which appear a little before the Squill-like, narrow foliage are of the size of a large Crocus and of a brilliant rosy-crimson-purple color, somewhat like our Meadow-saffron, but deeper and brighter. Good bulbs produce from 4 to 6 flowers, and when grown in clumps or patches on rock-work or in a sunny border they make a charming sight about this tiresome time of year.

Baden-Baden, April 1.

Cultural Department.

The Gladiolus.

Fig. 25.—*Hymenocallis Palmeri*.

A Hybrid Poplar—*Populus Steiniana*.—Mr. Bornmüller, the Inspector of the Botanic Garden at Belgrade, figures and describes in the last number of the *Gartenflora* a Poplar found by him on the western coast of the Black Sea, near Varna. The young branches are described as hoary when young, afterwards glabrous; buds hoary, petiole compressed; leaves hoary beneath when young, subsequently glabrous, deltoideo-triangular, acuminate, lobed, toothed. The flowers and fruit are not known. The tree is named in honor of Mr. Stein, of the Botanic Garden, Breslau.—*Gardener's Chronicle*.

FEW plants are so easily managed and none will give greater satisfaction in proportion to time, labor and money expended, than the Gladiolus. It dislikes a stiff, clayey soil, but will thrive in almost any other; its preference being for one of a moist, sandy nature, or light loam. For the best results, both in flowers or bulbs, fresh soil—that is, sod ground, with the turf nicely turned under to decay—is most desirable. This should have, after plowing, a surface dressing of well-rotted manure, well harrowed in. In light soil the bulbs should be planted four or five inches deep; in heavy loam two inches of covering will be sufficient.

Successive plantings on the same ground should be avoided, and the locality of the bed should be changed so as not to return to the same spot for at least three years. It is the better plan to make the ground very rich for a desired crop this year and plant Gladiolus on it the next. This plan cannot be well carried out in small gardens, but practice should conform to it as nearly as possible.

The time for planting is the first consideration in Gladiolus culture and its importance is almost wholly overlooked. In spring-time we rush into gardening with the first favorable weather and try to do all our planting at once, but a succession of flowers is what the amateur should aim at. This applies to all plants in the flower

garden, but with more force to the Gladiolus than to almost any other, because the flowers that one bulb will produce are so quickly gone that a succession can only be kept up by repeated plantings. The spring fever in gardening creates a desire to have everything at the earliest possible moment, whether seasonable or not, and early planting of the Gladiolus brings the flowers in the very hot, dry weather of our mid-summer, when in its natural habitat it flowers in the rainy season. For perfect flowers a moist atmosphere is necessary; to that end the bulbs should be planted from the first to the middle of July, and they will then come into flower about the first of October, when the days are cool and the evening air moist. Any given variety coming into flower at that time will give spikes of blooms much larger and stronger and the colors will be far better than if the same are produced in mid-summer. A succession of bloom may be kept up from July until frost by planting every two weeks, commencing as soon as the ground is in a suitable condition to work.

Selection is a matter of taste. As a rule we should grow such as increase moderately fast and are conspicuous for positive colors, well defined markings, and for long well formed spikes. Having secured such a stock, it may be increased to any extent by growing the small bulbs or bulblets that form at the base of the new bulb. These are produced in greater or less quantities on different varieties. Some will average a hundred per year, others scarcely any. The light colors have less vitality, as a rule, than the dark ones, and consequently do not rapidly reproduce. This will in a great measure account for the marked difference in the prices of the named sorts; it will also account

for the rapid increase of the more common varieties and the sudden disappearance of those greatly prized. Choice varieties are usually short lived, and the only way to keep up the stock is by bulblets, while the more common ones will rapidly increase by division. Old bulbs of some of our best named varieties will not produce good flowers, if, indeed, they produce any; this is particularly the case with Shakespeare and Ophir. They invariably give their finest spikes the second or third year from bulblets. Consequently the bulblets of all favorite sorts should be saved and planted each spring,

at least in sufficient quantities to furnish the desired number of flowering bulbs. Should it be necessary to throw away any through fear of over production, always discard the oldest stock.

The question is frequently asked, "Do the varieties sport or return to the original type, or do the white and yellow forms put on the scarlet?" To all such queries the answer must be an emphatic "No." "But then," continues the querist, "how is it that flowers are now all red? The first year or two of my growing them my collection was the best I could obtain, now they are not worth planting." The reason is simple; none but those with the strongest vitality have increased, the others have died.

The bulblets may be sown in early spring in any convenient out-of-the-way place in the garden, if the soil and situation is good, such as would yield a good crop of potatoes; they will, with proper attention, make bulbs that will flower the second season. The first season they will require but little room. Make the drills the same as for beet seed, and about two inches deep; sow the bulblets so thickly that they will touch each other, as they do much better than if sown thinly. No further

Picea Ajanensis, Fischer.—This very beautiful Spruce-fir, which has been introduced into our collections under the name of *P. Alcockiana*, Carr. (*Abies Alcoquiana*, Veitch), thus confounding it with another species, is perhaps second only in ornamental value to the Rocky Mountain *P. pungens*, Engelm. Nearly all of the specimens of so-called *P. Alcockiana* now in cultivation in the United States, are really this species, which may easily be detected by its pale yellowish tinted bark, flattish, very glaucous leaves, twisted at the base on the side branches, and small, or sometimes large, oblong cones with undulated deeply notched scales. It is reported to be a much smaller tree than *P. Alcockiana*, generally growing from 25 to 50 feet high, while the latter attains the height of from 90 to 120 feet.

P. Alcockiana is closely related to *P. obovata*, and *P. Ajanensis* is so nearly allied to *P. Menziesii* of our north-west coast, as to be almost indistinguishable from it in its botanical characters. Indeed, the late Dr. Engelmann considered at one time, that it was a mere form of the latter, but subsequent study enabled him to pronounce it specifically distinct; and Dr. Masters has recorded that it differs from the American species "in its flatter, less deeply keeled, and blunter leaves."

Santa Ritas Foot-hills, with *Quercus oblongifolia*.—See page 142.

work will be necessary, than to keep the ground clean and loose, until it is time to store the bulbs, in the autumn.

There are few pleasures in gardening equal to that which comes from raising *Gladiolus* from seed. The certainty of getting some remarkably fine varieties cannot be questioned; and it is equally certain that there will be some quite the reverse. Upon the whole, when the seed is saved from the best flowers, there will be many new combinations of form and color, and but few plants that need be discarded. The prevailing opinion that it is difficult to raise new and choice varieties from seed is erroneous.

It is no more trouble to raise *Gladiolus* from seed than to raise the most common vegetable. With the simplest garden culture there is an almost absolute certainty of success, if care in the selection of seed has been exercised. Prepare your bed in spring as for any hardy annual; the soil should be made fine and comparatively rich; sow the seed in drills, at a convenient distance apart to be worked with a hoe; cover to the depth of one inch; keep the soil light and clean; take up the bulbs after the first frost; store during the winter in a dry cellar or room, free from frost, but not warm; plant the bulbs again in the spring following, and the next summer very many of them will flower. As a rule, the more choice flowers will be found among the latest to bloom.

C. L. Allen.

In growth, it is rather slow at first in comparison with other species, but after having become fully established its development is rapid and satisfactory. It cannot perhaps be called a very graceful tree, as the arrangement of the branches is somewhat stiff and formal, but the picturesqueness of its habit is much enhanced by the decidedly unique commingling of the dark shining green and silver of its foliage. This peculiarity is noticeable at all times, as the rigidity of the leaves displays the charming glaucousness so characteristic of this species, even when in a state of rest. When standing in a group of other Conifers, especially those with dark tinted foliage, the contrast is exceedingly striking and rich. Its hardiness in the Northern States, even when small, is unquestioned, and although it requires a deep rich alluvial soil to accelerate growth and develop its beauty, it will succeed in almost any situation where other Spruces will thrive. *Fosiah Hoopes.*

Psychotria jasminiflora, or, as it is more commonly known in gardens, *Gloneria jasminiflora*, is a beautiful Brazilian shrub, with handsome evergreen foliage and pure white, fragrant, tubular flowers, produced in terminal corymbose panicles. It was discovered by Libon in the province of St. Catharine, in southern Brazil, as long ago as 1860, and is very well figured in the *Botanical Magazine*, t. 6454. It is not a difficult plant to

cultivate, and thrives and flowers freely during February and March in a warm green-house or stove, if potted in a compost of fibrous peat, leaf mould and silver sand, and grown on rapidly in summer in heat and abundant moisture. Like many other beautiful winter blooming stove-plants, it is too rarely seen in American collections. A fine specimen was shown by Mr. Hunnewell at the recent exhibition of the Massachusetts Horticultural Society.

Rhododendron Dauricum sempervirens is the earliest of all the *Rhododendrons* in flower. It is an erect, very hardy shrub, with small evergreen leaves and rose-colored flowers, single, or in twos and threes, on the end of the branches. In ordinary seasons it flowers in New England early in April, often before the snow has disappeared. S.

Tulipa Kesselringii was the earliest of the Tulips in flower in the New England rock-garden, where it was blooming freely during the last days of April. This is a dwarf and very hardy species, discovered a few years ago in Turkestan by Dr. Albert Regel, and distributed from the St. Petersburg Garden. The leaves are glaucous, lance-strap shaped, about six inches long, and crowded at the base of the stem. The flower-stem is short, four to eight inches long, and bears a bright, clear yellow flower, one and one-half to two inches long, the outer segments at first slightly flushed with red and green on the back. It is a very handsome and desirable species, recalling in habit and in the color of the flowers the Greek Tulip (*T. Orphanidea*), although belonging to a quite distinct group of the genus. *Tulipa Kesselringii* appears in some garden catalogues as *T. Hoeltzeri*. It will thrive in any good, well-drained garden soil.

Primula rosea, protected in a cold-frame, is in full bloom on the 1st of May. This is one of the loveliest of all the *Primulas*, and deserves a place in every garden where spring flowers are cultivated. It is a dwarf, compact Alpine plant, with tufted leaves, only a few inches high, and intensely brilliant colored rosy-pink flowers, nearly an inch across and with a conspicuous yellow eye. The stout, low flower stems are four to ten flowered. *Primula rosea* is a native of the snowy ravines of the western Himalayas, Kashnir and Afghanistan, where it is found at an elevation of ten to twelve thousand feet above the sea. Its hardiness has not yet been established here, but it is well worth the protection of a frame in winter, from which it can be transplanted in April to flower in the rock-garden or in the open border. It would not be easy to find among early flowering hardy plants a more striking and beautiful object than a mass of this Primrose.

Primula cortusoides, in its Japanese form known as var. *amana*, and sometimes as var. *Sieboldii*, is perfectly hardy here, and although not yet in flower, is now pushing up its crown of leaves vigorously. It is a handsome plant with ovate, cordate, dark green leaves, with many lobed margins, tall, slender scapes, and mauve or lilac colored flowers. It is often cultivated and much prized by the Japanese.

The Bloodroot (*Sanguinaria Canadensis*), a native of our northern woods and an excellent rock-plant in cultivation, is also in bloom now. The pure white, star-shaped, handsome, solitary flowers appear before the leaves, which are large, rounded and palmately lobed, and make an attractive and conspicuous mass of green throughout the summer.

Boston, May 1st.

C.

Streptosolen Jamesoni.—This plant deserves all that "W. F." says about it (page 33), but the fault that gardeners find with it here is its somewhat straggling habit of growth. But perhaps we grow it here in too high a temperature. A cooler treatment would probably induce a more compact growth. I have never seen it so fine as when Cannell of Swanley showed it a few years ago for the first time. Though an old plant with several of those who were at the show, the profusely flowered specimens, brilliant like balls of fire, took many by surprise. I think "W. F.'s" treatment in plunging out-of-doors in summer is the secret of success.

Aquilegia longissima, the new Columbine that Mr. Sereno Watson describes at page 31, may be a fine plant, but from the description I imagine that it is too much like the common yellow *A. chrysantha*. *A. Skinneri* is no good out-of-doors with us here, beautiful though it be. *A. Canadensis* is the best red Columbine for borders, but it is a trouble to keep it pure. So readily does it hybridize with *A. chrysantha* and our common *A. vulgaris*, that if seedlings are raised and they come up self-sown everywhere they are sure to be hybrids if the three kinds grow within reasonable distance of each other. You probably

have the race of beautiful hybrid Columbines that Mr. Douglas, one of our most noted gardeners, raised a few years ago. He said he intercrossed *A. corulea*, *A. chrysantha*, *A. Canadensis* and others, the result being a charming race of varieties with large, long-spurred flowers of every shade of tint possible to find in *Aquilegias*. They have now found their way into most good gardens, and being hardy and giving no trouble to grow well, they are favorites.

Parry's Lily.—That note from Mr. Pringle concerning the habitat of *Lilium Parryi* is most valuable, as it gives us just the information we wanted as regards the conditions best suited to this lovely Lily under culture. Hitherto it has been considered rather a delicate kind, but during the last two or three seasons some growers have apparently hit upon the treatment the plant likes, and the finest specimens I saw of it last summer were growing in a damp spot in peaty soil, in such a place as Mr. Pringle says it grows wild. Like *L. Canadense*, *L. pardalinum* and other of your native Lilies, I think that *L. Parryi* needs moist treatment and partial shade such as that afforded by a thin wood.

Narcissus in Water.—The beautiful illustration given on page 44, showing a *Narcissus Polyanthus* in water, is a revelation to most people in England. The majority of those to whom I showed the picture were unaware that *Narcissus Polyanthus* could be grown so finely in water, and no doubt the experiment will be tried before long by not a few. It is by bringing these somewhat out-of-the-way methods of flower-culture into notice by good illustrations that the best interests of progressive gardening are served.

W. Goldring.

The Forest.

The Forest Vegetation of North Mexico.—IV.

TO come now to the dry mountain ranges which rise at intervals from the plains to an elevation of 6,000 to 8,000 feet, between the Sierra Madre, which is the eastern verge of the plateau, far more favored as respects rain-fall, and comparatively rich in the number of its arborescent species, and the other Sierra Madre, or Cordilleras, of the western verge, we find *Pinus Chihuahuana*, *Engelm.*, pre-eminent in value among their sparse and stunted growths. In that fringe of the forests of the Cordilleras, which spreads out for a few miles upon the plains at their eastern base, I have seen this species developed into a noble tree, three feet or more in diameter, and sixty or seventy feet in height; but on these mountains its diameter is commonly less than twelve or fifteen inches, and its height less than forty feet. Of slow growth here, and showing more or less of dead branches or their stumps, with its sooty bark and its burden of old persisting cones, its aspect is unthrifty and melancholy.

To the building of Chihuahua, and other towns and villages, and the scattered homes of rich and poor throughout that region, this Pine must have contributed largely. The small amount of wood used in the construction of a Mexican house is astonishing to an American; yet none but cliff dwellings are possible without a little wood. The walls are composed entirely of earth and stone, and the floor may be of earth or tiles; but for the few doors and windows a little sawed lumber must be had; and, to support the heavy covering of earth, straight and strong timbers about eight inches in diameter (vegás) are indispensable, though they must be brought on the backs of mules and donkeys from mountains 50 or 100 miles distant. Just such timbers, straight, strong, and light for transportation, when disbarbed and seasoned, this Pine supplies; and there is hardly a mountain crest or slope to which the *peon* and his donkey could climb, that has not been searched to procure the vast number required. For the other lumber needed the trunks of the larger specimens in cañons have been sawed in the mountains with whipsaws.

Juniperus occidentalis, *Hook.*, var. *conjungens*, *Engelm.*, Juniper, is a common species of these ranges, and ranks next to the last in importance among their non-deciduous species. With a diameter of eight or ten inches in its

best development on the broader summits or in cañons, it supplies timbers for supports in mines, which well resist decay.

By far the most abundant trees, however, are Oaks, represented by two species, *Quercus Emoryi*, Torr., and *Quercus grisea*, Leibm., both evergreen, the former predominating about the base and in the lower cañons, the latter on the drier slopes and summits. Growing where they find more room and light than moisture, they branch low and form broad heads, and make very meagre annual growths. Old age overtakes them by the time they have reached a diameter of twelve or sixteen inches, and the axeman usually finds them hollow and defective. Their wood is brittle, knotty and contorted, of little value except as fuel, of which it supplies by far the larger part used in the country. Cut into short lengths, and split if large, it is bound by ropes to the backs of donkeys, a good wheelbarrow load on either side, and thus carried from mountain heights and steep to ox-carts at the base, or more often quite to the distant town.

Quercus oblongifolia, Torr., a species similar in character and quality to *Q. grisea*, is, so far as I have explored, comparatively scarce. (See illustration, page 140.) I suspect its range is mainly on the Pacific slope, with its centre of distribution in southern Arizona or Sonora; while *Q. grisea* is of most extensive distribution—from southern Colorado southward as far, certainly, as the State of Michoacan.

Quercus undulata, Torr., var. *breviloba*, Engelm., also resembling *Q. grisea*, seems to be a smaller tree than that, to be less common, and to grow on lower hills.

Quercus undulata, Torr., var. *pungens*, Engelm., is but a shrub forming thickets in cañons.

The ash, *Fraxinus cuspidata*, Torr., usually considered a frutescent species, I have seen in deep cañons attaining arborescent dimensions—a diameter of six or eight inches and height of twenty feet. On account of its large panicles of white flowers and their exquisite, pervading fragrance, it is worthy of being brought into cultivation wherever practicable.

A few other arborescent species occur on those ranges visited by me, but as they are stragglers merely from other districts this is not the place to describe them.

C. G. Pringle.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—Let me add to your lists of Rhododendrons the names of the varieties that have proved hardy on Long Island. Album, Album elegans, Album grandiflorum, Bicolor, Blandum, Caracacus, Charles Bagley, Charles Dickens, Cælestinum, Candidissimum, Everestianum, Gloriosum (Parsons), Grandiflorum, Glennyannum, H. W. Sargent, Lady Armstrong, Lee's Pallida, Mrs. Milner, Perspicuum, Purpureum elegans, Purpureum grandiflorum, Speciosum, Roseum elegans, Roseum superbum.

The following are American seedlings: Abraham Lincoln, Aurora, Bertie Parsons, Dr. Torrey, Flushing, General Grant, Henry Probasco, Maximum superbum, Purpureum crispum, Roseum luteum.

There are others, like Blandyanum, which do well only when protected from the north and west wind, and others which are still on trial. The American seedlings are exceptionally hardy; it would be useless to speculate upon the cause.

It is difficult to understand why certain varieties should be hardy in Boston and not here and why the converse also prevails, unless one knows the environment, and the shelter, not of covering, but of adjacent plantations. Then too the manner of growing has much to do with it. Those grown in peat except in wet places have not the vigor which will endure cold. Mulching may modify the injury, but in the dry weather of American summers peat is very injurious. Our own garden soil is light loam and during thirty years we have found this the best. After full trial we have avoided peat as we would noxious insects.

While thus asserting that good free garden soil is the best adapted to the Rhododendron, and while always striving to give our plantations open exposure, I readily admit that on the borders of ponds or in heavy adhesive clay, peat or sand ma-

be useful. I would not, however, place them in such positions while I recollect that the native habitat of the Rhododendron is less in valleys than on the sides of hills and mountains.

Your remark that a limestone soil is injurious is doubtless true, but that should never be an obstacle to their culture when leaf mould or other good material is easily obtained.

The sorts we mention doubtless owe their immunity to the fact of their being grafted plants as well as being grown without peat. Propagation by layers is still practiced in Europe, where old methods are persistently adhered to, but if we examine carefully the cause of the weakness of the layer will be manifest. A layer is put in the ground, slowly forms a callus, then slowly throws out its feeble rootlets, and, after long and severe efforts, makes a root ball which will go in a tumbler. In grafting, a scion is put upon a vigorous stock of *R. Ponticum* and then grows into vigorous life with a far better root-support than the best *R. Catawbiense* can give and which will fill a half peck measure before the layer root will fill the tumbler.

Layers also sprout in several branches from the ground and may be useful for thickets. In grafted plants the whole strength springs into one central shoot. One advantage of grafting them is that we may use the more vigorous root and open bark of *R. Ponticum* as a stock. A stock of *R. Catawbiense* or *R. Maximum* would be outgrown by the scion.

The weaker the constitution of a variety, the more difficult it is to make it thrive on its own roots; it requires the support of a stronger stock. Even strong varieties are improved by being grafted. This is illustrated by General Grant, which originally had very small trusses, while plants grafted from it have good sized ones.

Properly prepared, the stock of *R. Ponticum* rarely suckers with us. If it did we should not be deterred from grafting any more than the grower of Pear trees is deterred from grafting or budding because Pear stocks will sucker.

The preceding remarks apply also to the Ghent Azalea. Twenty-five years ago we had *Azalea coccinea* from layers and cuttings. In that time they have never grown over 1½ foot high and always flowered poorly, while the plants grafted from them made in five or six years more than the same height of healthy wood.

In 1873 we received from Belgium 3,000 Azaleas in 300 varieties; the grafted plants alone proved good; the layered plants were worthless and dwindled away. The same experience and rule applies to Magnolias, Camellias and Chinese Azaleas.

Many years ago and after repeated experiments we came to the conclusion that for this country layering was the worst mode of propagation that could be adopted. Subsequent experience after grafting over 200,000 Rhododendrons and proportionate quantities of other plants has thoroughly confirmed us and we now rarely use layering for any plant.

Flushing, N. Y.

Sam'l B. Parsons.

[We have never seen Rhododendrons successfully grown on a limestone soil, but have known of many failures where the utmost care was exercised and every expedient to overcome its deleterious effects tried. That peat is injurious in a Rhododendron bed is contrary to general experience.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—I was glad to see the article in your issue of April 18th calling attention to the success of the Japanese in landscape gardening. The subject is of extreme interest to all who care for art in connection with gardening, and I trust that some day you will be able to treat it more extensively and accurately than has yet been done by any European writer. Meanwhile perhaps the following extract from a German book—Reinhold's "*Japan und die Japanesen*"—may be welcomed by your readers.

"I do not know any other nation which has such a love for nature and its beauties as the Japanese. Scarcely a house is to be seen without a garden, in the laying out and keeping up of which no pains are spared. But as in most cases the space for gardens is very limited in the cities, the Japanese take great delight in miniature creations which, however, are very different from those one finds in China. The Chinaman's taste runs to the unnatural. His plastic representations are not copies, but caricatures of nature, and to our ideas are most repulsive. He lavishes time, money and labor on such constructions and finds satisfaction in having created something that harmonizes as little as possible with nature. His dwarf trees, artificial rocks and miniature landscapes therefore attract our attention to be sure, but not because they are beautiful—merely because they are curious. A criterion of their

æsthetic value appears in the fact that we never have the desire to copy or possess them, or even to gaze upon them for any length of time. Quite the contrary is the case with Japanese productions of this kind. Here we see the same dwarf trees, the same imitative groups of rocks, the same grottoes, lakes and landscapes; but even at first sight we are captivated by the fact that we find nature in them all. We are especially surprised by the completeness of the copy. We see that such things could be produced only by the most refined and subtle taste. Not only is nature imitated with painstaking fidelity to her smallest details, but in these artificial creations even her more romantic beauties are portrayed. As in their painting the Japanese labor under the same disadvantage as the Chinese in ignoring the rules of perspective, it astonishes us all the more to see that in their gardens every law of this science is obeyed and that we are unable to discover even the smallest transgression. Occasionally a garden of this sort will scarcely occupy an area of more than thirty or forty square feet, but in itself it is a finished whole which not only satisfies but delights the eye and heart by its faultless beauty. Forgetting that it is a product of art, we are transported to a Lilliputian world such as our childish fancy loved to seek in fairy-tales.

"In consequence of its mountainous surface Japan is very rich in the beauties of nature, and the variety of its flora increases them in no small degree. The hedges and bushes are brilliant with Camellias and Azaleas; tree-like Rhododendrons cover the hill-sides; the feathery leaves of the Bamboo wave in the wind alongside of the wide-spreading branches of the sacred Fir-tree; and by the dark Japanese Palms (*Rhapis*, *Chamærops*, *Cycas*) glow the red leaves of the Maple or the rich greens of the Waxtree (?). Wherever there is a beautiful view we may count with certainty upon finding a convent, a temple or a tea-house. They prove, however, that a Japanese resorts to miniature creations only when he is obliged to forego nature herself. Wherever she surrounds him he can enjoy her without constraint. There he neither imitates her features nor strives to force them into other shapes, but is quite satisfied with her natural aspect. Therefore we never find artificial gardens or parks where nature has created their like."

It need only be added, as was remarked in your article already referred to, that although when nature is beautiful the Japanese does not resort to artificial arrangements of any kind, he nevertheless always tries to develop nature's intentions to the full, to remove all discordant details, and to heighten by gentle care the native character of the spot. So beautifully and unobtrusively is this done, that the eye of the tourist may well be deceived into thinking that man has done nothing, where in fact he is daily doing much. E. G. G.

To the Editor of GARDEN AND FOREST :

Sir.—Can you inform me why it is that horses and cattle can eat with impunity the shoots and leaves of the "Poison Ivy"? It is a well known fact that they are particularly fond of this plant.

Tiverton, R. I.

Nanequacut.

[It is not at all uncommon for animals to eat with impunity some vegetable poisons which are fatal to man, as there are some animal poisons fatal to cattle and not injurious to man. No instance is recorded of the poisonous action of *Rhus* upon the lower animals, at least among Mammalia. Dr. Bigelow refers to an account of bees being killed by swarming upon *R. venenata*, and it is stated that insects never attack the Japanese Varnish-tree. References to this immunity of the lower animals will be found in Professor James C. White's recent publication upon the action of external irritants upon the skin. What is more strange is the complete immunity of many individuals of mankind from the action of all the poisonous species of *Rhus*, who can chew the plants and rub them upon the skin without the slightest irritative effect, whilst the mere passage along a road bordered by the plants is sufficient to provoke a severe inflammation of the skin in others.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—Allow me to take exception to Mr. Dana's wholesale condemnation of the Norway Spruce, in his pleasant letter on Conifers. It is indeed a somewhat stiff and prudish tree, and has been doubtless over-planted in the way of making decorative

green tufts about too many homesteads. But in fullness of age, when it shows a great array of fleecy, pendent branchlets, and of tawny cones, it has a majesty of its own. Moreover, scarce one of our native Conifers, when mature, keeps such vigor in its lower limbs; thus insuring, for single planting, a pyramidal piling up from the very turf of a tower of evergreen. Our black and white Spruces, our Balsams, our Pines (the Scotch Pine even more noticeably), are apt to show a beggarly array of lower limbs, and to put all their forces into the tops, when they come to fruiting age. Again, the Norway Spruce takes the shears very kindly for hedge purposes, or for screens; its dwarf varieties are particularly amenable to the moulding clips of any gardener or householder who may have topiary whims to indulge. But most of all is this old favorite to be commended, I think, for its hardiness—its sturdiness—and its every-day farm utilities. It will bear rough handling; is easy of removal; it stands drought; it makes the quickest and best of wind shelters; its insect deprecators are of the fewest; it does not break down under press of ice or snow, as the White Pine and Hemlock are somewhat prone to do.

Edgewood, Conn.

Donald G. Mitchell.

[The trouble is that the Norway Spruce in this country rarely if ever reaches "fullness of age" in a healthy condition.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—Professor Penhallow's notes on the Snowberry and its relationship and resemblance in flavor to the Gaultheria reminds me to say that I have known the berries of Gaultheria used in the same way as a conserve. In the southern counties of the Maryland and Delaware peninsula the Gaultheria is very abundant in the black, swampy spots called "savannahs," and the berries are largely sold under their Indian name, "Yopon."

Recent Publications.

C. F. HOLDER'S *Living Lights, A Popular Account of Phosphorescent Animals and Vegetables* (Chas. Scribner's Sons, New York), is chiefly taken up with an account of the animals in which light-producing phenomena have been observed, such phenomena being more frequent and more conspicuous in the animal than in the vegetable world. But two chapters are devoted to luminous fungi and to plants and flowers which, at least under certain conditions, have been seen to emit light. As long ago as 1762 the daughter of Linnæus observed, during a twilight hour, a "lightning-like phosphorescence" about the flowers of the Nasturtium, and stated also that when she approached the flowers of the White Dictamnus with a light "they appeared to ignite, without, however, injury to them." Many scientific men at that time threw doubt or ridicule upon her statements, but they have since been confirmed by hundreds of observers, and, as a correspondent of GARDEN AND FOREST recently set forth, the inflammable nature of the emanations from *Dictamnus Fraxinella* is well known to-day. Not only the Nasturtium, but the Poppy, the Sunflower, the Garden Marigold, the Orange Lily (*L. bulbiferum*) and the French and African Marigolds (*Tagetes patula* and *T. erecta*) have been seen to emit flashes which have "the exact appearance of summer lightning in miniature," and are probably, in fact, electrical in their nature. The nature of the phosphorescence so frequently observed in decaying wood and also in many fungous growths produced in caves and mines has never, according to Mr. Holden, been accurately determined. But the flame which is emitted when *Dictamnus* is brought into contact with a light, has nothing electrical and nothing inexplicable about it. Dr. Hahn wrote in 1857 that he "held a lighted match close to an open flower [of the White Dictamnus], but without result; in bringing, however, the match close to some other blossoms, it approached a nearly faded one, and suddenly was seen a reddish, crackling, strongly shooting flame, which left a powerful aromatic smell, and did not injure the peduncle. Since then I have repeated the experiment during several seasons; and even during cold, wet summers it always succeeded, thus clearly proving that it is not influenced by the state of the weather. In doing so, I observed the following results which fully explain the phenomenon. On the pedicels and peduncles are a number of minute reddish-brown glands, secreting etheric oil. These glands are but little developed when the flowers begin to open, and they are fully grown shortly after the blossoms begin to fade, shriveling up when the fruit begins to form. For this reason the experiment can succeed only at a limited period when the flowers are fading.

The radius is uninjured, being too green to take fire, and because the flame runs along almost as quick as lightning, becoming extinguished at the top, and diffusing a powerful incense-like smell." At the close of a hot, dry day the oil is, of course, drawn from these glands in larger quantities than at other times, and then we may count upon the possibility of igniting it in the atmosphere, even though the match be held at some distance above the plant.

Bulletin of Miscellaneous Information. Royal Gardens, Kew. No. 15. March, 1888. Eyre & Spottiswoode, London. Two-pence a Number.

The object of this useful publication is to bring within reach of every one interested in plants, in a cheap and accessible form, the mass of valuable information which is always accumulating in the Kew establishment.

The last number contains an article on *Forsteronia* Rubber, the product of *Forsteronia gracilis* of British Guiana, "a large twining plant, the stem of which trails on the floor of the forest, snake-like, and the head spreads over the tops of the highest trees above." The good quality of the samples of rubber yielded by this plant indicates that it would be a promising commercial undertaking to collect it if the plant is found in sufficient quantities. Another article is on Patchouli, a well-known Eastern scent distilled from the leaves of *Pogostemon Patchouli*, and familiar as the odor connected with India shawls. The Patchouli plant is a native of the East Indian Islands, where the leaves form a considerable article of commerce. The present number contains also articles on west African Indigo plants; on the Vanilla, and the advantages of undertaking its extensive cultivation in the West Indies and other tropical countries where this Orchid is not indigenous. Directions for its cultivation and minute instructions for artificial fertilization of the flowers (illustrated), an operation which will always be necessary in countries where the peculiar insect which deposits the pollen upon the stigma of the Vanilla flower is not found, add to the value of this article. There are articles on *Streblus* paper, made in Siam from the bark of *Streblus asper*, a tree widely distributed through India, Ceylon and tropical Asia, and closely related to the well-known Paper Mulberry; and on *Usera* Fibre, the product of a Natal plant (*Usera tenax*), and, finally, on various samples of tea grown in Jamaica, in Madagascar, and in Natal, where experiments in tea-growing on a considerable scale are now being made.

Public Works.

Historic trees and shrubs for Central Park.—More than twenty years ago Mr. James Hogg began to plant in his grounds at Eighty-fourth Street and the East River the novelties which his brother Thomas Hogg was then sending from Japan. At one time there were collected here more than 300 species and varieties of trees, shrubs and herbaceous plants, mostly from Japan and China. Most of these were the first specimens of their kind to reach this country and many of them were received here some time before their introduction into Europe. Some years ago Mr. Hogg disposed of the place, and the trees and shrubs have been somewhat neglected, and yet the collection has continued to be a most interesting one. But the time has come when the space must be covered with buildings and through the efforts of Mr. Hogg the trees and shrubs were presented to the New York Park Department and most of them have been carefully removed to the north-eastern part of Central Park, where extensive improvements are in progress. Among the trees are fifteen varieties of the Japanese Maple which are specially interesting as first importations. The first *Magnolia hypoleuca* was too large for removal and efforts will be made to protect it where it stands. A Japanese *Styrax* of extraordinary size and a remarkable Tree Peony with large single purple flowers are among the other treasures.

Small Parks for Philadelphia.—A noteworthy meeting was held on Wednesday evening of last week at Association Hall, Philadelphia, under the auspices of the City Parks Association, to aid the movement in favor of creating at once seven small parks in various parts of the city, and ultimately to increase this number to a score at least. Ex-Governor Hoyt presided, and Mr. Herbert Welsh, as Secretary, read a strong memorial, which is to be presented to the Councils. Stirring addresses were made by President Smith, of the Common Council; Charles Emory Smith, of *The Press*; Col. A. K. McClure, of *The Times*; Professor Rothrock, Rev. Dr. M. Connell, Drs. White and Ashhurst, so that all the phases of the question—political, economic, sanitary, social, scientific and moral—

were presented with unusual ability. The objects of the new Association commend themselves to the sympathy and active support of all public-spirited men and women.

Retail Flower Markets.

NEW YORK, May 12th.

The supply of cut flowers is very heavy and the quality is generally poor, particularly that of Hybrid Roses. Paul Neyrons sell at from 40 to 75 cts., and Baroness Rothschilds from 35 to 75 cts. each. It is only in fashionable localities that 75 cts. is charged for a selected Hybrid Rose. On Broadway and Fifth Avenue florists struggle to keep up prices to a reasonable figure, but on side streets good flowers may be bought for nearly half price. The average run of General Jacqueminot Roses may be had for 15 cts. each, but selected ones cost 40 cts. American Beauties range from 20 to 50 cts. They are not as much in favor as General Jacqueminots. Puritans cost from 35 to 40 cts. Moss Roses sell for 50 cts. a spray on Broadway and for 25 cts. a spray on Sixth Avenue. Bride and Catherine Mermet Roses cost \$2 a dozen. La France brings from \$2 to \$4 a dozen. Papa Gontier and Souvenir d'Un Ami cost \$1 a dozen. Perles des Jardin and Niphetos the same, and Bon Silenes from 60 to 75 cts. a dozen, while Mde. Cuisins bring \$1.25 a dozen. Tulips are becoming scarce. They are from out-of-door beds, and the majority of them are spotted—the effects of the blizzard. They cost 75 cts. a dozen, the same as good Lilies-of-the-Valley. Roman Hyacinths have disappeared. Pansies are 25 cts. a dozen, and are extremely handsome. Southern Lilacs are selling for 15 and 20 cts. a spray. Carnations cost 35 cts. a dozen, excepting the Buttercup variety, which brings 50 cts. There are a few Dutch Hyacinths to be had for \$1 a dozen. Gladioluses are 25 cts. a spike. Daffodils cost 75 cts. a dozen, fine Forget-me-nots are 35 cts. a dozen, and Mignonette ranges from 35 to 75 cts. a dozen. There is considerable of the white variety in market, but it does not sell as readily as other sorts. Callas bring \$2, and blooms of *Lilium longiflorum* \$2.50 a dozen. Sweet Alyssum and Auricula are appearing in floral shops. Small clusters of each cost 10 cts. Violets are from 75 cts. to \$1 a hundred, and poor. Smilax is 40 cts. a string, or from 25 to 30 cts. a yard. *Asparagus tenuissimus* brings 75 cts. a string.

PHILADELPHIA, May 12th.

"Spring flowers," which are called for very frequently—more so, perhaps, than anything else, excepting, perhaps, Roses—are nearly all cut from cold-frames or out-of-doors now. Their season will soon be past. The prices keep up surprisingly. Choice Tulips bring \$1 a dozen readily; these are varieties which are too expensive for forcing. The rarer kinds of Trumpet Narcissus, such as Horsefield's, Empress, and occasionally a few flowers of "Grandis," are eagerly bought at \$1 a dozen. They are very beautiful. Tea Roses are not of as good quality as they were ten days or two weeks ago, nor are Jacqueminots and other Hybrid Remontants. American Beauty is the best Rose now offered, and it appears to be the favorite, bringing the highest price—\$5 per dozen. Baroness Rothschild, Magna Charta, Paul Neyron, Mde. Gabriel Luizet and Mrs. John Laing sell at from \$3 to \$5 a dozen. Jacqueminots, \$1.50 to \$3.00; Mermets, Brides and La France, \$2; Perles, Sunsets, Niphetos and Madame Cuisin, \$1 to \$1.50. This last variety is very fine just now, being an exception to the general rule, as it improves with the advancing season, brighter sunshine and warmer weather. Papa Gontiers sell at \$1; Bon Silenes, 75 cts.; Lilies-of-the-Valley, 75 cts. to \$1; Carnations, 35 cts.; Pansies, Marguerites, Forget-me-nots and Heliotropes, 25 cts. a dozen; Mignonette from 25 cts. to 75 cts. Many conservative Philadelphians do not take kindly to *Asparagus*, preferring Smilax, while others are becoming tired of the older kind of green for large decorations. A new vine, differing in appearance from either of those named, which could be grown satisfactorily and cheaply, and that would stand well in heated rooms, would be an acquisition at this time. Something of the kind indicated is on trial at Baltimore, which will be watched with great interest.

BOSTON, May 12th.

There is little change in the cut flower market. Trade in this line is quiet just now, owing possibly to the charms of out-door flowers and shrubbery which the pleasant weather has brought suddenly forward. The auction sales of bedding plants have commenced in earnest, and many people are devoting their attention to the beautifying of their out-door surroundings. Still there is no great over-stock of good flowers in the market, as the crop is light at present on everything, and those who buy the best Roses find that they must pay full prices. There are but few Hybrids now, and the price remains at about \$6 per doz., for selected blooms. Jacqueminots are more abundant and of extra quality; they sell for \$4 per doz. Smilax is still scarce at 50 cts. a string and demand is light. Violets are poor in quality; these and Pansies bring \$1 per hundred; the latter are of extra quality, in fact there is no doubt that Boston takes the lead in Pansy flowers. Pansies and Mignonette have received increased attention for two or three years past and in their greatly improved quality are becoming deservedly popular. Long stemmed Carnations are 50 cts. a dozen for the ordinary kinds. Grace Wilder and Buttercup Carnations always command higher prices than any other; selected blooms of these varieties are worth \$1 per doz. Callas and Lilies are in good supply at \$2 per dozen.

Rural Improvement Societies.

IT is now some twenty years since the first village Improvement Societies were organized and the history of many of them justifies every reasonable hope in which they were founded. Some were established for a single purpose—as, for example, the laying down of sidewalks or the planting of a public square—and when this end was well accomplished they were formally disbanded. Others entered upon a wider field of usefulness and there is still no abatement of their beneficent activity. Under their influence public spirit has been stimulated and public taste has been cultivated; the health of country communities has been guarded by more wholesome surroundings and country life has been made more satisfying and attractive. Need enough there was and still remains for such organizations, for it is not alone in city sewers and crowded tenements that the seeds of disease are festering. Heaps of offense reek in country hamlets and by rural road-sides; poisoned water pours into country wells and fever-laden gases are generated in village cellars. We cannot hope that much natural beauty will survive under the trampling of a great city's population, but there is no justification for the neglect by rural communities of the natural beauty which appeals to them on every hand, still less can excuse be found for the wanton disfigurement of the native graces of the country by those who should be most concerned in conserving and developing them. The associations which have adhered with intelligence and zeal to the purposes for which they were constituted have accomplished even more than the most hopeful could have anticipated, for their work is seen not only in beautified road-sides, in more general cleanliness and health and in largely increased land values, but in a growing local pride as well, in a more alert intellectual activity and in a more elevated social life.

But there have been failures, too, or at least apparent failures, and these were foredoomed in any community where but comparatively few were interested. A small band of enthusiastic and well-instructed people can accomplish much when they have won the help of their

neighbors, but work of this kind cannot prosper until there is a general co-operation. The effort to overcome inertia and opposition is too costly and wearisome for any but the most courageous and patient. It may be incorrect to characterize the efforts at reform under these depressing conditions as failures, for genuine earnestness in a good cause is never altogether wasted. But in too many instances the zeal of the few has been only superficial, or what is quite as bad, it has been uninstructed; and just here lies the fundamental reason for the most signal failures.

It requires no special skill to keep streets and yards clean and road borders tidy, but it is an art to build a good road, and unless the construction of a highway is planned and supervised by a trained engineer it will probably be impassable when the frost is leaving the ground the next spring. Amateur sanitarians make wild work when devising a system of drainage for a town, as an outbreak of fever is too likely to demonstrate. Amateur tree-planters who place White Pines in heavy, undrained lowlands, and set half hardy and shortlived exotics on bleak and barren knolls, will have a discouraging experience when their cherished trees sicken and die. If the service of an expert is needed for the preparation of a creditable design for the improvement of private grounds, how much more is special training demanded when an entire town is to be treated with a view to the development of its landscape possibilities! It cannot be expected that the private dwellings of a village will all be remodeled into beauty and harmony under the directions of a competent architect, but the advice of such an artist would be invaluable not only in designing the public buildings, but in giving caution and counsel even down to such details as the village fences, the tree guards and the town pump.

All this means that while the love of order, the good taste and the intelligence of many communities will suffice to make a genuine improvement in village homes and their surroundings, the full measure of the possible usefulness of those associations can only be attained when they are directed by counsel of training and experience.

It is true that skillful masters in every department of the work to be undertaken are not always available and it would not be wise for every community to postpone action until their services were secured. But it is prudent in every case where enterprises of this nature are contemplated to move with deliberation and to make a careful study of the entire field before actual work begins. Much can be learned from the experience of other societies. Some of them publish admirable lists of trees for planting. The officers of those that have been most successful in this direction will gladly explain their methods of planting, and subsequent care of the trees, which is of equal importance. The annual reports of the most prosperous are full of information and suggestion on many important matters, including the best methods of raising funds and of enlisting the co-operation of the town authorities. We learn from one of the interesting letters we have been receiving from the Secretaries of various societies, that a movement has been started to form a New England Association of Village Improvement Societies. The discussions at an annual convention of delegates from all the local organizations throughout the Eastern States could not fail to be helpful.

With all these opportunities for instruction, it may be hoped that new associations will be able to avoid certain errors into which the pioneers in this movement were naturally led. And yet the counsel of a trained landscape gardener would be invaluable in every large enterprise, even when the most is made of all the means of instruction that have been named. To the objection that such counsel is expensive, the general reply may be made that the best is always the cheapest. And more specifically it may be said that when any considerable outlay is to be made, much more and much better work will be accomplished when a fair percentage of money expended is paid for the best advice that can be obtained.

Labels.

A THOROUGHLY satisfactory label for a plant has not been invented; and yet a good label is one of the most important elements of a good garden. It should be indestructible, cheap and unobtrusive, and it should be made of a material upon which ordinary writing will be durable and legible. The labor involved in naming and in preserving the names of a large collection of plants is so great that experiments are constantly made with different materials, in the hope that something may be found that may answer all the requirements of a good label, at once cheap and durable. The results of many such experiments have been presented in a most interesting and instructive paper, lately read before the Massachusetts Horticultural Society by Mr. Robert T. Jackson, of Boston.

Metal labels are more durable than wooden ones; and zinc, Mr. Jackson finds, is the metal most commonly used, as it is cheap and reasonably durable. Bright, fresh zinc, first cleaned for the purpose with very weak muriatic acid, may be written on with an aqueous solution of chloride of platinum or chloride of copper. These solutions can now be purchased from dealers in seeds and garden supplies; and a quill pen is the best thing to use for writing with them. Labels thus prepared need no further attention. Zinc slightly roughened by oxidation, which is easily produced by leaving it for a few weeks in a damp place, may also be written on with a soft lead pencil. The writing soon becomes indelibly fixed on the zinc, and is as permanent as if the chemical ink had been used. Labels prepared in this way are known to have been legible ten years after they were written, and are, Mr. Jackson considers, about the most satisfactory to use out-of-doors.

Iron, or tinned iron, painted a neutral tint and lettered, is also used sometimes for labeling large trees, but copper, chemically one of the most stable metals, would no doubt make a better label, the names being written on it with a white or light-colored paint. On smaller copper labels, names, as Mr. Jackson suggests, "could be very easily and rapidly marked by an etching process as follows: Heat a sheet of copper, rub over with etcher's wax, and when cool, write the names with a steel point, laying bare the copper on the lines of the writing, expose to nitric acid and water—equal parts—for a few minutes, clean off the wax with turpentine, and cut up the copper into suitable-sized labels." Pure tin—not the tinned iron usually known as tin—is recommended for labels to be used in a warm green-house temperature, where other metals are subject to extreme corrosion. Names or numbers can be easily stamped with common steel dies into any of these metals, and stamped labels are more permanent than written ones. And even when it is desirable to write the name on a metal label, a supplementary number corresponding to a number in a written record of the collection adds immensely to its value. A narrow strip of lead stamped with a name or with a number and wound about the stem of a plant is used in many European establishments, and makes a permanent label, although it has to be taken off the plant to be read. Different styles of pottery labels have been tried, but they break easily, and the careless blow of a spade will finish the best of them. White porcelain labels, with the letters burned in, and set in iron frames, are neat and indestructible, and perhaps the best which have yet been devised. They are far too expensive, however, for general use. Mr. Jackson calls attention to a white composition label, in use in the Botanic Garden at Geneva, which can be written on with a pencil or with indelible ink, but this would probably prove almost as brittle and easily broken as pottery.

Wood is more generally used, however, in this country, for labels, and probably always will be. Well-selected white pine labels, soaked in linseed oil, will last for a number of years, and white pine is probably the cheapest wood of its durability which can be obtained for this purpose. California redwood is very durable, and not

now very expensive. It holds paint well, and makes an admirable label, and so do the wood of the Southern Cypress and the Catalpa. The last, however, is not commonly found in the market. Locust makes a very strong and durable label, but it is expensive and its surface is coarse for lettering. Labels made of pine, or of other not very durable woods, when used in the ground should have the lower portion carefully coated with tar. A pine stake so prepared, and then painted with two coats of good paint before being lettered, will last for eight or ten years. It is a rule, which, so far as possible, should never be deviated from, that the label should be securely attached to the plant itself. It is easy to do this in the case of trees and shrubs, but with annual, bulbous and herbaceous perennial plants the label must be placed in the ground near the plant. There is always danger that such labels may be lost or misplaced. The record, therefore, in regard to such plants, is much more difficult to preserve than in the case of trees and shrubs. A metal label with the name and a number plainly stamped into it, and securely attached to a branch with a piece of good strong copper wire is the best record which has been devised, and such a label should be placed on trees and shrubs whenever it is important or desirable to keep a record of their history, even when they are labeled in a more conspicuous manner for the benefit of the public. It must be borne in mind, however, that labels attached to branches or the stems of small trees should be examined every year, and the wire loosened whenever the growth of the plant causes it to bind the bark. Many plants are ruined from neglect to attend to this precaution. This is the great danger, and the only drawback to labels fastened in this manner.

The best label for a large tree, when it is desirable to instruct the public by this means, is a piece of cold rolled copper, twelve inches long by eight wide. The upper edge should be bent nearly at right angles with the face of the label, to make a narrow hood in order to protect the letters from rain and moisture running down the trunk. The Latin and English names of the tree, and its native country, should be printed in some light neutral tint, and the label should be tacked on the trunk with stout copper tacks, at the height of the human eye.

Trees with trunks too small to carry a label of this description, shrubs, and perennial and annual plants, can be labeled with stout stakes prepared in the manner already explained, and driven into the ground deep enough to resist the heaving influence of the frost. A neater label for such plants, although more expensive, can be made by suspending a small oblong metal or wooden label with copper wire to a slender galvanized iron rod, bent at one end into an eye. The rods should be not less than three-sixteenths of an inch thick, and from eighteen to twenty-four inches long, in order to enable them to have a firm hold on the ground, and to carry the label well up in front of the plant. Such labels, although more expensive, have this great advantage over stake-labels that the writing upon them can be made horizontal to the eye, and therefore much more easily read. They are, moreover, more durable—indeed such labels if carefully made are practically indestructible, and they are less objectionably conspicuous. They should supplement, however, in the case of small trees and shrubs, the small metal label attached to a branch.

The Senate of New York acted wisely and in accordance with the most enlightened sentiment of the State when it defeated the bill authorizing the Forest Commission to lease the public lands under their charge to private individuals. Not to repeat the objections to this measure which have already been presented in these columns, it may be said that the building of many houses and other permanent structures which was invited and encouraged by this bill would go far to rob the North Woods of that wildness which is one of their principal attractions. A fringe of painted villas and fences about an Adirondack lake would certainly add nothing to its charm.

Roadside Beauty.

WHEN this part of the country was first settled a rail fence, half a mile long, was built on the line between two neighbors. This was renewed by pieces and remained the barrier between the two farms for thirty-five years. These men were not representatives of the highest type of snug, thrifty farmers. They were tree slayers and bared their acres of everything that stood in the way of the plow or mowing machine. But along this line fence they stored the stumps and stone and other rubbish that impeded their work, and bushes and young trees soon sprang up. The row of wild growth became a grand place for Raspberries and Blackberries when I was a lad, and the regular harvest of Hazel Nuts came from the same thicket. It was a famous place, too, for rabbits and squirrels, partridges and quails to hide in.

But a new set of landholders came in to revolutionize the neighborhood. A few tree lovers settled here and my father was one. He bought the farm on one side of the line hedge and another progressive farmer bought the adjoining one. A highway was laid out on this half mile of line; the two thrifty farmers cleared out the old fence, burned up and hauled away the rubbish, and with pruning implements weeded out the useless and carefully saved the most promising trees in the greatest possible variety, the different Oaks, the wild Black Cherry, and the Elms predominating. They were left in groups, no effort being made to save trees at regular intervals. These trees grew rapidly, and a fine road-bed was made on either side. It is, to-day, the most beautiful half mile of road in all our county, the pride of every one who loves a tree or appreciates natural beauty.

But the race of vandals is not extinct. Land became valuable and was bought up by speculators who were anxious to cut the acres into small lots and get rich. They wanted to "improve" the neighborhood and "make it attractive." They sought to widen the highway for a mile and a half, including this half mile, and make it into a "boulevard," with a wide road-bed in the centre, a sidewalk on the borders, and rows of trees on either margin, "the way they do in Chicago." I objected mildly, upon the general plea of "no cause." They pressed harder and extolled the beauty and grandeur of a generous boulevard, with every undulation taken out of it, and a grand American Elm on either side once in sixty feet. They pictured the noble residences that would be erected on its borders and the delight with which they would grub out that unsightly, irregular, obstructive row of trees, and have no break in the road-way from end to end. I became impatient, wanting none of their improvements, caring little for a view of fine residences on forty-foot lots, with an ownership of two-thirds of a dead Elm tree planted in front.

Of course I was set down as lacking in public spirit and obstructing intelligent progress.

Surely it is not true progress to lay out every suburban highway on some Metropolitan model and take all the individuality out of a neighborhood. Refined taste does not commend the obliteration of all native and natural beauty, to make room for some formal scheme of an engineer's devising.

We cannot have trees, shrubs and vines on the business streets of a city, and get any satisfaction out of them, but on our highways, in the suburbs, there is no reason why these untamed graces may not only be preserved and protected, but rendered more attractive by delicate attention. This may be small work for a landscape gardener, but it is good work for some kind of an artist, who not only appreciates Nature, but is willing to adopt some of her methods in rendering beautiful the surroundings of homes that have not the advantage of park-like grounds or magnificent distances.

Many of the most attractive highways in our State owe their beauty to the shiftlessness of the pioneers, who allowed a mass of bushes to grow up in the corners of the

old worm fences undisturbed for a generation; afterward to be utilized by their more thrifty successors in the embellishment of the roadsides. No plantations formed by man are equal in beauty to these irregular masses of trees that are of Nature's planting.

Occasionally I note an example of the workings of some man's mathematical mind, who has tried to clear out one of these rows, leaving a tree once in so many feet, and thus ruining the effect for all time. No one can pass along a highway fringed with one of these wild borders without a feeling of gratitude to those easy-going settlers who allowed Nature to do what she could to compensate for man's wholesale destruction of forest beauty, which was a necessary sacrifice, perhaps, to advancing civilization.

We need not be sentimentalists of the kind that refuse to destroy a tree that has passed its usefulness, or that stands as an obstruction in a cultivated field, but we should have a wholesome respect for Nature's attempts to beautify the waste places of the earth, and especially for the way-side shrubbery, which gives attractiveness to the roads we all travel and ought to enjoy.

The Two Types of Cemeteries.

AS a matter of design, burial places are of two distinct types of character—the architectural or formal, and the rural or picturesque.

The *Campos Santos* of most Latin countries are instances, though often deplorably poor ones, of the formal type. Most of the larger cemeteries of this country are instances of the rural type.

It must not be thought, because we are most accustomed to the rural cemetery, that it is the only good kind, and that the formally designed place of burial is foreign, antiquated, puerile, and in every way undesirable. The truth is that each type has merits of its own. Both should be had in mind when it is proposed to create a new cemetery, and all the special conditions of the case should be well considered and the decision as to which to adopt should be made according to the balance of advantages.

Cemeteries of the formal type may well be adopted in districts where the soil is too poor, the climate too hot and dry, or too cold and bleak, for the successful growing of trees, shrubs and turf; or where the available area is very limited in proportion to the number of burials to be expected; or, what comes to much the same thing, where the land is excessively costly; or where the tastes, habits, knowledge and skill of the people strongly incline them to work out more artistic results in architecture than in landscape gardening. The architectural or formal style lends itself to the multiplication of large and costly monuments as well as small and modest memorials, each with some individuality, but forming part of a comprehensive design, the scope of which may range from a geometrical, garden-like court, to a great building of the most monumental and dignified character, or from a city block to a great wood with formal alleys and vistas running through it. The principle admits of uniting the highest achievements of architects, sculptors, painters, and other artists, with the most skillful gardening, and the most choice trees and shrubs, into one rich, harmonious and satisfactory whole.

As, however, the fashion of making cemeteries in what is intended to be the rural style has become firmly established in this country, through the existence in parts of it of favorable conditions, a few suggestions as to that style will be of more practical interest than a further discussion of what may be accomplished in the formal style. As one of the results of the increased thought which has, of late years, been given to the high arts and to those of architecture, interior decoration and furnishing, a sentiment has begun to spread among us of dissatisfaction with the appearance of many of our noted rural cemeteries.

If one were to ask, more in particular, the occasions for this dissatisfaction, the complaints would probably be made that the monuments, though costly and made in a sufficiently workmanlike manner, are so generally commonplace and devoid of originality and imagination; that the habitual use of white stone amidst green verdure forms too violent and too frequent contrasts; that the incongruities between the monuments are intensified by their being crowded together while but little attempt is made to screen one from another; that the monuments, their decorations, and their architectural and gardening accessories are so often entirely inappropriate to the purpose in view; and that the necessary and unnecessary artificial objects are multiplied to such an extent as to completely dominate and sometimes even obliterate the natural elements which can alone give any excuse for the use of the term rural as applied to a cemetery.

There is sufficient ground for these complaints to enforce the reflection that whatever is built by man can be designed and executed with due regard to artistic as well as to mechanical principles. There are canons of good taste which should be as well known to landscape gardeners as to architects and other artists, and these, if intelligently applied to rural cemeteries, even though by men whose artistic ability is not the very highest, would secure far better results than those to which we are now accustomed.

J. C. Olmsted.

Foreign Correspondence.

London Letter.

THERE was a fair crop of new and rare plants exhibited at the Royal Horticultural Society's meeting yesterday and thirteen certificates of the first class were awarded. The finest plant at the meeting happened to be an old green-house climber *Bignonia Tweediana*, first introduced to Europe from Buenos Ayres fifty years ago. But it has never been shown in such perfection before, otherwise it would have been awarded a certificate, as it was by a unanimous committee on this occasion. Like most other Bignonias, it is a shrubby climber, having long slender shoots, which (as the specimens showed) become wreathed with a profusion of large showy flowers of a rich warm yellow. They are fully three inches across and remind one of an Allamanda, but is a far more graceful and pleasing plant. It has been commonly grown in England as a stove climber, but now it appears that it wants a green-house temperature in order to flower well. In any case it well repays any amount of attention, if it can be made to bloom freely, as these specimens from Pendell Court.

Another plant of importance was a variegated leaved form of the common *Cordyline indivisa*, erroneously called *Dracæna indivisa*. It has a symmetrical tuft of long, narrow leaves, which, in this novelty, are broadly marked with a whitish yellow band on each margin, giving the plant a pretty effect. A new single Rose, a variety of *R. polyantha* and named *grandiflora*, was certificated because of the profusion of the large white flowers and buds, together with the luxuriant foliage of the plants exhibited, which, of course, had been forced. Those who like single Roses will like this one. It was shown by Paul, of Cheshunt.

A pretty little crested, fronded Selaginella named *S. cuspidata crispa* was next certificated. This is only a few inches high and the fronds are like a feathery moss of a cheerful green. It came from B. S. Williams, who makes a specialty of new Ferns and Selaginellas. He showed also a rare Maidenhair Fern (*Adiantum Ethiopicum elatum*), a tall growing and extremely elegant plant, but as the committee were doubtful about its difference from similar kinds of Maidenhair Fern, it was passed.

The white variety of *Iris stylosa*, which has been placed before the committee at two previous meetings this year, was at length honored with a certificate. The albino is

precisely similar to the typical *I. stylosa*, excepting the absence of color and the fact that its flower season extends over several weeks is, in itself, a great merit in a plant from Algeria that flowers naturally out of doors in our climate.

Among the numerous Amaryllises shown there were few that conformed with the high standard that has been agreed upon among Amaryllis fanciers. The flowers must not only be large, but must show an advance in the direction of perfect form, while the color must be distinct and good. The finest of the five certificated was called Conqueror, which has flowers quite eight inches across, with broad and nearly equal petals of a glowing scarlet, with greenish white centre. The variety Finette is very lovely, as its large and finely formed flowers are pure white, save a few pencilings and splashes of crimson on the sepals. Rodney has flowers of a vivid scarlet, not so fine in size or form as Conqueror, while one called Miss Roberts has white flowers exquisitely netted and veined with heavy lines of deep crimson. The above were all certificated from the group shown by Veitch & Sons. A very fine variety was certificated from B. S. Williams. It is named Emperor Frederick and is remarkable for the very large flowers, not so open as those shown by Veitch, but its rich scarlet color makes it an exceedingly fine variety.

Two new Tree Carnations from Turner, of Slough, were thoroughly worthy of the certificates awarded to them. They were Purple King, with large rosette-like flowers, three inches across, of a rich plum purple, and Mrs. Grenfell, best described as a magnified form of the popular Miss Joliffe, as its large flowers have the same pleasing, delicate, salmon pink color. Both will be invaluable sorts for winter and early spring flowers. From a number of named sorts of Cineraria, all of very dwarf, dense and compact habit shown by James, the committee selected for a certificate one called Maria, which has enormous flowers of pure white with purple centres. Some object to certificating Cinerarias because the sorts do not come true from seed, but the same may be said of most other florists' flowers. James' best named sorts are propagated by cuttings.

Wm. Goldring.

The Banded Hickory Borer.

THIS insect is common, I think, wherever Hickory grows, but it has received comparatively little attention from entomologists. It appears to work more particularly on timber that has been cut, and frequently wood that has lain for a year or two after being felled has been found so full of galleries, that its value, even for firewood, is greatly lessened, while it is rendered entirely worthless for manufacturing purposes of any kind.

In Figures 26 and 27 are shown, reduced one-half, cross and longitudinal sections of a hickory stick, picked out of cord wood from a great number fully as badly eaten. From these sticks were secured a number of the grubs and pupæ, and later, in May, the adult beetles issued, so that its life history can be pretty fully stated. The eggs (Figure 28, a and b) were obtained from the bodies of adult females, as many as ninety-three being found in the body of a single one. Judging from the fact that cord wood and felled timber are so badly infested by the borers, while standing wood appears to be but slightly attacked, it seems that adult insects must select cut timber in which to deposit their eggs.

The young grubs commence channeling the wood at once, but it is not known certainly how long it requires to attain full growth. The cord wood mentioned above as furnishing the adult beetles, had probably not been cut for more than two or three years at the most, and we can safely assume that the eggs in this case were laid after the wood was cut, which would limit their life to two or three years. On the other hand, instances are recorded where the adult beetles have issued from furniture, carriages,

etc., some time after their manufacture. This would indicate a much greater longevity, though the instances are probably exceptional. When full grown the grub is yellow and has the appearance shown in Figure 28 at *c*. It is provided with three pairs of very minute legs, scarcely distinguishable without a lens. At this time it may be found in a burrow in the hard wood, but which has been carried to the surface or at least to the bark. The burrow is an ellipse in a cross section as shown in Figure 26, and in some cases reaches half an inch in its longer diameter, but may extend for three or four inches, running with the grain of the wood. The change from this stage to the chrysalis stage (Figure 28) takes place in the latter part of winter or in spring, occasional ones being found as early as the first of January. The gallery in which the change

Fig. 26.—Cross section of Hickory stick showing galleries of *Chion cinctus*. Diameter, $\times \frac{1}{2}$. (From nature, by H. Osborn.)

to avoid injury. Timber cut in the fall or early winter, and becoming thoroughly dried before the beetles appear in the following summer, will not be so badly attacked, which very likely accounts for the superstition concerning the proper time of the moon in which to cut timber. It is often asserted, also, that if the bark be peeled off no damage will be done. This, although wanting accurate experiment, seems to be well founded. Timber intended for use in the factory, if valuable enough to warrant the expense, could be protected by housing it before the latter part of May, care being taken that windows or other openings in the shed or building, large enough to admit beetles, be protected by means of wire screens.

Herbert Osborn.

New or Little Known Plants.

Delphinium viride.*

THIS Larkspur (Fig. 29, page 150) of the mountains of Chihuahua is a novelty in its combination of colors. We have Larkspurs blue and Larkspurs white, also pink and scarlet, and even occasionally yellow; but here we have the sepals and the long, stout spur of a decidedly yellowish green, while the short petals in the centre are deep purple. The species is probably a biennial or a winter annual, with a rather stout root, and is about two feet high. It was found during the last season by Mr. Pringle on gravelly bluffs along streams at the eastern base of the Sierra Madre. Seeds were secured, and it is hoped that it may be successfully grown. S. H.

Cultural Department.

How to Prepare a Bed for Roses.

THE amateur can grow Roses equal in quality to the fine specimens which are seen on exhibition tables; but to do this there must be no misstep in the cultivation from the very beginning. And at the very beginning must be met the questions, "Where shall we plant and how shall we prepare the soil?"

The bed should be somewhere in a fairly open place, where the plants can have at least 6 or 7 hours of sunshine from April till November. If the shadow of a house or fence falls on the bed three or four hours a day the result will not be fatal, but sunshine all day is to be preferred. Again, the bed must be away from trees; not only from under their shade and drip, but so far away that their roots do not rob the bed of its moisture and fertility. Finally, never plant Roses in an old bed or border where Roses have been growing before perhaps for years. If no other place is available, all the old soil to the depth of two feet should be dug out and carted away and the bed filled in with good fresh soil. This point is of vital importance.

Any good loamy soil, when properly fertilized, will grow Roses. By good loamy soil I mean soil ranging between what gardeners call light sandy loam and heavy clay loam. But where the soil approaches the first limit—that is, where it is of a light, sandy texture, it will be materially helped if some clay or heavy loam is mixed with it. On the other hand, a heavy clay loam will be rendered more porous and better if some sand is thoroughly forked through it.

Of course the bed can be shaped to suit the fancy, but beds star-shaped, or with any other intricate outline, such as we see made for Coleus and Geraniums, are not to be commended. The Roses look better, and can be better cared for, in a circular bed or square block. For a dozen plants a round bed need be no more than four feet six inches in diameter. Nine plants can be placed at equal distances in a circle about 8 or 9 inches from the border, and the remaining three can be placed within this circle at equal distances from each other and from the outer row. A bed eight feet eight inches in diameter will accommodate three dozen plants if they are arranged in three circular rows fifteen inches apart, with seventeen plants in the outer row, twelve in the next, six in the next and one in the centre.

*D. VIRIDE, Watson, Proc. Am. Acad. xxiii, 268. Glaucous and mostly glabrous, 2 feet high; leaves pedately cleft, the segments acutely lobed, the upper leaves more deeply and narrowly divided; flowers rather few, on long pedicels; calyx pubescent, yellowish greens, the sepals 6 lines and the stout spur 10 lines long; petals purple, 3 lines long; capsules pubescent.

Fig. 27.—Longitudinal section of Hickory stick showing galleries of *Chion cinctus*. Diameter $\times \frac{1}{2}$. (From nature, by H. Osborn.)

takes place is loosely filled with chips, before and behind the chrysalis, so that it is partially protected, while no difficult boring is left for the adult to perform.

The adult beetles (Figure 28, *e*, male; *f*, antennæ of female), for the specimens I reared, issued quite uniformly during the last two weeks of May. These are grayish-brown in color, an inch or more in length, and have commonly a yellowish oblique band on each wing cover. This band, however, is often wanting. The front part of the body is cylindrical with a sharp spine at each side, and there are two spines at the end of each wing. The antennæ of the males are more than twice the length of the body, while those of the female are only about the

Fig. 28.—*Chion cinctus*.—Drury. *a*, eggs, natural size, *b*, enlarged; *c*, larva, full grown; *d*, pupa, side view; *e*, adult male; *f*, antenna of female. (From nature, by H. Osborn.)

length of the body. It is evident that any measures designed to protect the timber must be adapted to the time and method of egg deposition, since it is utterly useless to attempt the destruction of the grubs after they have become established in their burrows. Growing timber is so slightly affected, that its protection is not necessary; but timber intended for manufacturing purposes, and even for firewood, unless used the first year after felling, must be protected

When the beds are cut on the turf the border should be marked sharply, and a strip of sod cut out clean with a spade. The soil should be then taken off to the depth of 10 or 12 inches and laid on the outside of the bed. The subsoil should next be covered to the depth of three or four inches with well rotted stable manure, which should be forked in and mixed thoroughly to the depth of another foot. The top soil can then be thrown back, covered with another good coat of manure and carefully forked over. In case the subsoil should be found light or gravelly, it should all be carted away. The bottom should then be dug up loosely, and the top soil originally removed should be thrown in and manured as above. The bed should then be filled up with soil from an old pasture, using enough to raise the centre of the bed some three inches above the level of the margin. This should then be manured and forked. This will give a bed of fresh, healthy, active soil, and without this it is impossible to grow the finest Roses. It should be added that thorough drainage is another essential, for Roses will no more thrive in a water-soaked soil than in an unmanured bed of sand or gravel. This work is to lay the foundation of a bed that is to last for years, and it pays to do it well. Indeed, it is time and money wasted to do it in any other way. All subsequent fertilizing is to be applied to the surface. The bottom must be made once for all.

What Roses to plant in such a bed, and how to plant them, must be the subject of another article.

Summit, N. J.

John N. May.

Hardy Plants for Forcing.

THE first spring flower in our woods gives unusual pleasure, but it is quite as pleasing to see those vernal favorites among our green-house plants. Delicate and unassuming as they are, they will attract more attention than more showy exotics. These latter everyone expects to see, but the sight of a wild Columbine any time after Christmas always brings an exclamation of delight. Many of these hardy plants force readily in a cool green-house, and generally remain longer in beauty than when they flower at their normal season. Strong specimens should be selected to be potted in not too large pots in September or October, and plunged in a cold-frame with such plants as Violets. From the first of January, by which time they will be well rooted, they may be brought into the green-house, where they will flower within a period of from three to six weeks. After the flowering is over, and the ground open, they should be planted out again, and, if possible, new stock used for the next winter, to give them time to get well established before they are again used. It must be remembered that the majority of such plants do not require higher temperature than 50° by artificial heat, as the sun in reality does more towards the forcing than the heat. A liberal supply of fresh air should be maintained to prevent damping off, and to keep away the green-fly, which is apt to infest them in closed houses.

Doronicum Caucasianum is well fitted for forcing, and needs but three or four weeks to expand its blooms, which are of deep yellow and over two inches in diameter. This makes an excellent pot plant for decoration, and the long-stemmed flower could be used for cutting. It is a native of the Caucasus. Similar to this is *D. Austriacum* and *D. macrophyllum*. Care should be taken that the plant is not kept too wet, as it decays easily.

Trillium grandiflorum, a beautiful native plant, succeeds well when forced, and the flowers last a long time in perfection. It requires about four weeks to bring it into flower. Cultivated roots should be used instead of collected ones, and if well cared for after the flowering season it might be used for two or three successive winters with good results. This is very useful for cutting and decoration.

Aquilegia Canadensis, our graceful wild Columbine, forces in three or four weeks, and is useful for decoration, but does not last long enough to be used for cut flowers.

Campanula persicifolia and its white variety are two good plants to force. They produce long spikes of either blue or white bell-shaped flowers and last long in perfection. It is native of Europe and requires five to six weeks to bring it into flower.

Geum coccineum plenum, a beautiful plant which is only hardy on high and well drained grounds, makes a fine pot plant, and three to five weeks of green-house culture will induce it to push forth long stems of bright red, semi-double flowers, that are very striking.

Iris Germanica in varieties, and many others of the genus, are first rate plants for forcing. They take three to five weeks, and are very ornamental with their large and beautifully colored flowers.

Caltha palustris is a very bright and striking plant, on account of its large yellow flowers. This requires two or three weeks of forcing, and being rather common in our marshes it might be easily procured. *Phlox amana* make neat cushions of pink flowers in three or four weeks after it has been taken into the green-house.

Fig. 29.—*Delphinium viride*.

Viola pedata and *Viola cucullata* are very pretty when forced, and require only a few good bright days to flower them under the glass.

Smilacina stellata is very useful not alone as a flowering plant but for the sake of the delicate green foliage, and is very effective in finishing vases or other larger decorations.

The hardy and native *Cypripediums* are excellent plants for forcing. *C. acule* and *C. pubescens* require only three or four weeks of artificial heat, while the showy *C. spectabile* takes from five to six weeks. The *Helleborus niger* is a very useful and ornamental plant when kept in a green-house for about three weeks, but the heat must be moderate, otherwise they turn green instead of white. There are many others like some of the Saxifrages which could be named, but the above will suffice for illustration.

W. A. Manda.

[The number of plants which can be forced to bloom unseasonably with the aid of a little artificial heat is almost endless. It is a question, however, whether we do not lose more than we gain in thus changing the blooming period of hardy plants. The feeling of freshness and delight which spring brings, with its bursting flower-buds, is somewhat dulled if we have been looking at these same spring flowers under glass during the winter. Each flower has its appropriate season, and is best enjoyed at that season. Daffodils gave far more pleasure in April, and June Roses in June, before they became common winter flowers. Flowers out of season, like vegetables out of season, satiate the taste, without affording the real gratification which a flower or a vegetable gives in its proper season.]

The Japanese, who, as a nation, are certainly more fond of flowers than any other people, never force them. They are satisfied with their flowers as they appear in the course of nature, and make annual festivals and holidays to go out and enjoy the blooming period of the Plum, the Iris or the Chrysanthemum.

There are tender plants enough which can be grown under glass without dissipating the pleasures of the garden and the forest, and a return to a more general use of such plants is certainly desirable.—ED.]

Forsythias.—Gardeners recognize three species, namely, *F. Fortunei*, *F. suspensa* and *F. viridissima*. Mr. A. S. Fuller says he has obtained all three from seeds of *F. suspensa*. But in a garden sense they are decidedly distinct. The brightest and best is *F. Fortunei*; *F. suspensa* is like a trailing form of *F. Fortunei*, and *F. viridissima* in wood, foliage and habit, and in color of flowers is, to the gardener, distinct from either of the others. All are in their most showy condition about the first of May, and this is the time to note their own condition as shrubs and their position in the garden. They should never be scattered haphazard about a place like yellow patches in a "crazy quilt;" nor should they be buried in thickets of other shrubs, nor planted beside a doorway, or alongside a much frequented path, or anywhere else where their presence shall have a glaring and obtrusive appearance. A little way off, as individual specimens, or grouped by themselves, they have a pleasing effect. But let them be in the vicinity of other shrubs or trees, and rising from the turf.

In their wildest and most neglected state they often appear in their least obtrusive and most effective condition, because of their open, slender, graceful form—a shower of gold from their topmost twig to the ground. But in well kept gardens, as we have to regulate the growth of Forsythias and most other shrubs, we cannot allow them unrestricted growth. In many pretentious gardens, public and private, we often find Forsythias, as well as Privet, Japan Quince, Deutzias, and the like, clipped into close, round-headed forms. Such "well-trimmed shrubs" are hideous.

An old Forsythia in a neglected yard, with its golden wands rising and curving and drooping to the turf in fluent grace—surely this is more beautiful than a leafless lump that harmonizes with nothing in Nature. While we studiously avoid the clipped monstrosity, we must curtail the freedom of the wild plant if we would have a handsome shrub and profusion of bloom. And now, after the plants have done blooming, is the time to begin. Shorten back the young (last year's) wood to within a few joints of its base, and cut out gnarled, scraggy and weakly old wood; prevent overcrowding of either old or young wood, and if the shrubs have been neglected so that the old stems have grown up high, leaving the bottom naked, do not hesitate to cut them hard back. The points to be observed are: maintain a good supply of young wood from the ground up, and have the bushes open enough to admit light and air sufficient to well ripen the shoots before next fall, and in this way secure an abundance of flower buds for the spring's display, and work for medium-sized hard wood, rather than

stout, sappy growths, and do not cut out the little twigs. Never prune Forsythias from June till they have done blooming, except to thin out overcrowding shoots

H. F.

Campanulas.—In overhauling and top-dressing our rock-garden a few days ago I was astonished with the extreme hardness and accommodating character of the Bell-flowers. These sow themselves freely, coming up in crevices and on ledges everywhere. *C. Carpathica* produces some well-defined varieties and some fine hybrids. *C. turbinata* is one of the most distinct and best. The flowers are purple, and comparatively large, but the chief varietal distinction, and one always relied upon, lies in its being uniflorous. This variety comes fairly true from seed. *C. pelviformis*, also very handsome, was sent out by Messrs. Fræbel, of Zurich, as *C. turbinata pelviformis*, having been selected from a batch of the variety *C. turbinata*. This variety seldom comes true from seed, and needs to be propagated by division, which is easy. The variety *Hendersoni* is a distinct hybrid, never producing fertile seed—at least by its own pollen; what it would do if cross-pollinated by *C. Carpathica* I do not know, but it would be interesting to try. The plant's habit is stout, growing 1 foot high, having much-branched flower stems, the flowers being similar in shape and color to those of *Var. turbinata*, but much larger; altogether a handsome and somewhat rare plant. *C. Carpathica turbinata* × *pulla* is noteworthy on account of being a hybrid between two very distinct species. *C. pulla* is the prettiest of all the dwarf varieties, having wiry underground stolons and uniflorous flower stems with pendulous, truly campanulate flowers of dark purple. The hybrid retains the character of *C. pulla* (even to the extent of bearing pendulous flowers) in all but the shape of the flowers, which resemble those of *Var. turbinata*, except being a little smaller. *C. rotundifolia*, the "Harebell" and "Bluebell," grows about one foot high, producing graceful panicles of small, truly campanulate flowers.

T. D. Hatfield.

Magnolia stellata.—A fine specimen of this beautiful Japanese shrub, which flowered profusely a couple of weeks ago in a yard on Fifth Avenue, near the Central Park, attracted the admiration of the public. *Magnolia stellata*, which is also known as *M. Halleana*, was introduced a few years ago by the Messrs. Parsons from Japan, where it is a favorite garden ornament. It is a native of the forests which cover the slopes of Mount Fusi Yama, where it is said to become a small tree. Like *M. conspicua* and *M. obovata*, *M. stellata* belongs to the section of the genus in which the flowers appear before the leaves. They are white, deliciously fragrant, three inches in diameter, the sepals silky-hairy externally, oblong-obtuse, much shorter than the narrow linear oblong petals, which are at first spreading, giving to the flower when expanded the appearance of a pure white star. Later they become quite reflexed. The obovate leaves, borne on short petioles, are narrowly obovate, two to five inches long. *M. stellata* requires the same soil and cultivation as *M. conspicua* and the other Yulan Magnolias. It begins to flower freely when only a foot or two high; and is an important and interesting addition to our perfectly hardy early flowering shrubs. S.

Arsenical Poisons on Elm Trees.—The first brood of larvæ of the Elm-leaf beetle will appear in June. Timely applications of Paris green or London purple in water sprayed over and among the foliage of the trees will destroy this pest. But the spray will leave some poison on the grass. The poisoned trees need not be in a pasture lot nor around the dwelling-house to be a source of danger. If there is the least possible chance of horses, cows, sheep or other animals grazing about them, or of children playing there, the greatest caution should be observed in using arsenites.

A Group of Trees or Shrubs—A Suggestion.—Why not take Red Maple, Red Bud, Spice-bush, Shepherdia, Fragrant Sumac, Cornelian Cherry, Leatherwood, Japanese Corylopsis, and other trees and shrubs of somewhat similar character, which bloom before the leaves appear, and group them near each other in some park, or large wooded estate. Hazels and other plants bearing conspicuous catkins might also be admitted, but Magnolias, Forsythias, Japan Quinces, and plants with showy and discordant flowers excluded. As they differ so much in some other ways, much discrimination will be needed in using them. I have never seen such a group, but have a strong inclination to form one. R.

Plant Notes.

Japanese Apples.

OF the many species and forms of the Apple cultivated for the sake of their flowers, none is more beautiful than the plant introduced from Japan by Von Siebold, and known in gardens as *Pyrus floribunda* or *P. Malus floribunda* (*Fl. des Serres* xv., t. 158.—*Revue Horticole*, 1866, p. 312 with t.) Maximowicz has referred this plant to the Chinese *P. spectabilis*, but the deciduous calyx and very small persistent fruit seem to point rather to a derivation from the Siberian, Manchurian and north China *P. baccata*.

It is a vigorous shrub or small tree, very common in Japanese gardens, with long, straggling branches, forming a head sometimes twenty feet through. The bark is dark

Francis Parkman's garden in Jamaica Plain, where this Apple, now a stout bushy tree, perhaps eighteen feet in height, still flourishes. The same variety was afterwards sent to the Messrs. Parsons, of Flushing, by Dr. G. R. Hall, an American physician long a resident in Japan; and it now appears in trade catalogues, both as *Pyrus Parkmani* and *P. Halleana*. It only differs, however, from Von Siebold's plant in its semi-double, darker colored flowers; in the deeper color of the young leaves and peduncles, and in its smaller fruit.

No shrub or shrubby tree surpasses these Japanese Apples in marvelous abundance and beauty of bloom, which is most attractive, perhaps, just before the pink or red flower-buds expand and display the lighter colors of the interior of the flowers. It is astonishing that they are not better known and more often planted. They are beautiful as single specimens and still more beautiful

Fig. 30.—The Double Flowered Japanese Apple.

brown, or nearly black; smooth and shining. The leaves are oval, rather coriaceous, dark green above, lighter and somewhat pubescent on the under side. The numerous large flowers appear with the leaves; they are borne on slender peduncles three or four inches long, and completely cover the branches. The petals are oval-elliptical, longly unguiculate, rose on the outside, nearly white within. The abundant fruit from which the calyx falls before maturity, leaving a minute eye, is hardly larger than a pea; it is round or sometimes oval, dull yellow or red in color, and decays and then dries upon the branches before separating from the peduncles which remain attached to the branches until the following spring.

Our illustration above represents a flowering branch of a form or variety of this Apple from a plant which was sent to this country by Mr. F. Gordon Dexter, of Boston, about twenty-five years ago, with the first bulbs of *Lilium auratum* and the first plants of the golden *Retinospora* and of *Thuopsis dolobrata* which ever came to the United States. These plants found a home in Mr.

when grouped in great masses. They flower profusely when very small, grow rapidly and continue to improve for years. They thrive in all soils, and neither intense cold, great heat nor drought affect them. No foreign ornamental tree introduced into this country adapts itself more readily to its peculiar climatic conditions.

As Mr. Dawson has shown in some remarkable seedlings which he has raised at the Arnold Arboretum, the Japanese Apple, like the rest of the family, varies considerably from seed, and can be still further improved by careful selection—a fact of which enterprising nurserymen should not be slow to take advantage. C. S. S.

Heuchera sanguinea in Mexico.—Accustomed during several years to meet with this plant on the mountains of Arizona and Mexico, and always admiring its mottled leaves and striking flowers, I feel grateful to Mr. Hatfield for recommending it for cultivation, and am prompted to tell of a visit made last September to the station (or, at least, the vicinity) of its original discovery, whence Wislizenus in 1846 brought dried specimens to Dr. Engelmann, who praised it as "beautiful

and delicate, and certainly the most ornamental species of the genus."

The station is on La Bufa Mountain, overlooking the mining town of Cusihiurichic. Here, hanging from fissures of cliffs of porphyry facing northward, or planted on their narrow shelves, 1,500 feet above the din of the town and the smoke of its smelters, an abundance of strong plants was seen, their rosettes of leaves beautifully marked with white and purple in the strong light of the place, and their flower scapes—bright scarlet when fresh, but maturing or drying crimson—like light plumes tossing in the mountain breezes. From the nature of its habitat—cool ledges, either wet or dry, and even the rich humus at their base—this plant would be expected to thrive in rockeries; and that it will prove hardy in most climates may be inferred from the fact that along the northern limit of its distribution it is exposed to many degrees of frost.

. See Cent. Diet. *arnole*. C. G. Pringle.

Vegetable Soaps.—In widely separated countries there are plants, in some cases herbs, and in others trees, which the natives use as a substitute for soap in washing. Whoever has had his linen washed in northern Mexico will bear witness to the efficacy of the root called *axmole* in cleansing the linen, but his shirts will come back minus buttons, not so much caused by the deterative power of the *arnole*, as by the primitive washing machine used by the Mexican laundress, who selects a large flat stone upon the margin of a stream, upon which the fabric is laid, and beaten vigorously with another flat stone. The *arnole* root is the root of a species of *Phalangium*, one of the Lily family, and dried and made into little parcels, is sold in every small town. The soap-wort, *Saponaria officinalis*, common in this country, is known as "Bouncing Bet." This was used in Europe in washing as a substitute for soap, and in hard waters was preferred to it. The number of plants that may be used as a substitute for soap is quite large; the most important of which is the soap-bark tree of Chili, where it is called "Quillai," or "Cullai." The native name has been taken for the botanical name of the tree, which is *Quillaja Saponaria*. The genus *Quillaja* belongs to the Rose family, and five species are known, all South American; three are Chilean, one Peruvian, and one Brazilian, the most important being the *Q. Saponaria* of Chili, as its bark is largely used in its own country, and forms a considerable article of export. This is a large tree fifty to sixty feet high, with evergreen leaves, and usually small white flowers. Its bark, which is rough without, internally consists of light colored layers, which contain an abundance of saponine, which they readily impart to water, causing it to lather in a similar manner to soap. The bark is in general use in Chili on washing day, and is exported to other countries. It is to be found in our city drug stores, where it is in demand by those who wish to use it for cleansing silk materials. It is said to remove grease and other spots and to impart a remarkable lustre to woolen goods, and is used as a wash for cleansing the hair.—*American Agriculturist*.

The Rock-Garden in Spring.

Fritillaria pudica, although one of the first of the Rocky Mountain plants known to botanists, is very rarely seen in cultivation. It was discovered in the mountains at the head waters of the Missouri, in what is now the Territory of Montana, by Lewis and Clark, in their memorable journey across the continent early in the century, and was described and very well figured by Pursh in his North American Flora. It is a low, leafy plant, six to nine inches high, with alternate linear, glaucous leaves, and clear, bright yellow, pendulous, bell-shaped flowers, nearly an inch across. They are solitary, or sometimes produced in pairs. This plant does not always take kindly to cultivation, but it can be grown in a warm, sunny rockery, if the bulbs are planted deep in the ground, and careful drainage is provided for them. It is well worth all the trouble it takes to cultivate it, as it is one of the most delicately beautiful of all the *Fritillarias*, as all those who have had the good fortune to see great masses of this modest flower blooming far above the timber line, amidst the melting snows of the Rocky Mountains, can testify.

Orobis vernus is one of the hardiest and in every way most satisfactory of the early flowering herbaceous plants. It is a native of central and southern Europe and belongs to the Veitch Family. It grows about one foot high and forms a compact, bushy mass of foliage, which at this time is covered with handsome, nodding flowers. These are produced in great abundance on axillary peduncles, and when they first open are purple and blue in color, veined with red, later turning blue. The leaves are composed of two or three pairs of

ovate-lanceolate, acuminate, shining leaflets. This handsome Pea has been an inhabitant of gardens for 250 years, but it is not now very often seen in this country. It is entirely hardy and grows in any garden soil. It can be increased by division of the roots, or by seed, which is abundantly produced every year.

The Pasque Flower (*Anemone Pulsatilla*) is also in bloom. It is a handsome species of northern Europe and Russian Asia, long cultivated for its large, solitary, violet-purple flowers, very silky on the outside of the sepals. The carpels are long and feathery, like those of the Clematis. This plant succeeds best in well drained and dry situations, and naturally prefers a limestone soil. It forms, when well grown, handsome masses of delicate, finely divided foliage; and flowers freely. A beautiful and interesting form of the common wild Wind-flower (*Anemone nemorosa*), with perfectly double flowers, which was discovered in Connecticut a few years ago, is also flowering here. It is a plant of considerable value, lasting much longer in bloom than the common form.

Two very familiar northern wild flowers of the Lily Family, the Wake Robin (*Trillium grandiflorum*) and the Bellwort (*Uvularia grandiflora*), should find a place in every spring garden. *Trillium grandiflorum* is a low perennial herb, with a simple naked stem, bearing at the summit a whorl of three rhomboid-obovate leaves and a single large, spreading white flower, two or three inches across, and turning rose color in fading. *Trillium grandiflorum* likes a deep, rich soil, and prefers the shade of neighboring trees to the open sunny border, as its home is in northern woods. It may be increased by seed, although it is easier to obtain plants from the woods, which require, however, two or three years to become thoroughly established and to show their greatest beauty. *Uvularia grandiflora* has drooping, yellow, bell-shaped, Lily-like flowers, single or in pairs, at the summit of a slender, leafy stem, one to two feet high. It may be increased by division, and, like the *Trillium*, enjoys the shade of trees and a deep, rich soil. Few plants possess a more graceful, delicate beauty, or better repay the trouble of moving from the woods to the garden.

Corydalis solida, or, as it is often known in gardens, *Corydalis bulbosa*, is the earliest of the genus in flower. It is a pretty little herb a span high, with a tuberous root-stock and long-stalked biternate glaucous leaves, and rather large purple flowers in short terminal racemes. It thrives in dense shade, and is now springing up in all directions from self-sown seed. It is a perfectly hardy plant which may be expected to become thoroughly naturalized in this country. It is a native of central Europe.

More difficult to establish, and much more delicate and beautiful, is its near relative, the Dutchman's Breeches (*Dicentra Cucullaria*) of our western woods, now blooming here. It is a dwarf plant with grain-like tubers, which send up finely cut, graceful, glaucous leaves, and a slender scape, bearing four to eight pretty white flowers tipped with yellow. The generic name *Dicentra*, formed from two Greek words signifying twice and spur, refers to the two-spurred, heart-shaped corolla of these plants. *Dicentra Cucullaria* when first taken from the woods should be potted or boxed in rich sandy loam, and kept close in a frame or cool green-house until new roots are formed. It should then be wintered in a cold-frame and not planted out until spring, which operation should be performed without disturbing the soil surrounding the delicate roots. Once established in a rich soil and in a shady situation, it will require no further attention.

It is often supposed that the common English Primrose (*Primula vulgaris*) is not hardy in this country. Here it succeeds admirably on a dry, grassy bank, which is partially shaded in summer, but which now, when the plants are in bloom, before the neighboring trees have expanded their leaves, is in the full sun light. The only secret of success here with this charming plant is high, well drained soil, the use of good, strong, well established plants, grown in frames for the purpose, and a slight protection of dry leaves left in autumn where they fall from the trees. It well repays this slight trouble.

Boston, May 6th.

C.

Notes from the Arnold Arboretum.

THE earliest of all the great collection of *Prunus* in flower is *P. Davidiana*, a shrubby Peach from Mongolia, where it was discovered by the Abbé David, who found it also covering the hills in the neighborhood of Gehol (the summer residence of the Emperor), and near Peking. The specimens in the Arboretum were raised from seed sent by Dr. Bretschneider, long a member of the Russian Legation at Peking,

to whom the Arboretum owes many interesting plants. *Prunus Davidiana* is a shrub three to six feet in height, or, in cultivation, according to Franchet ("*Plantæ Davidianæ*," p. 103), a robust tree fifteen to twenty feet high. The bark of the branches and stem resembles that of a Nectarine, and without the fruit the most experienced Peach grower would hardly guess the true character of this plant. It has considerable ornamental value. The white, or sometimes pink flowers, are produced in great profusion, and the flower buds are much hardier than those of other Peaches. This suggests the possibility that this plant might be used in creating a new race of flowering Peaches able to bear the cold of the Northern States. The fruit, however, of *Prunus Davidiana* has no value. It is small, downy, nearly spherical, less than an inch in diameter, grayish white, turning yellow at maturity. The flesh is very thin, separating easily from the stone, even before the fruit is ripe, and is dry and tasteless, lacking almost entirely the odor of the Peach. It wrinkles on the branch before maturity, and soon decays. *Prunus Davidiana* is interesting as the representative of what seems a type intermediate between the Peach and the Almond. A few days later *Prunus tomentosa* is in bloom. This is a shrubby Cherry, forming a dense, compact and handsome bush three or four feet high. It is a native of northern China, whence, probably long ago, it was introduced into Japan, where Von Siebold met with it occasionally in gardens; and admirably figured it in his "*Flora Japonica*," t. 22. This species can be distinguished from the other members of the genus *Prunus* by the thick long tomentum which covers the entire under side of the leaves. The flowers which quite cover the long vergate stems are sessile or short stalked. They are white, tinged with pink, and about the size of those of the common Cherry tree. They open when the young silky leaves are about one-third grown; and the association of the handsome abundant flowers and delicate young foliage is particularly attractive. The handsome fruit ripens in July; it is round or nearly oval, almost transparent, deep scarlet in color, and has a pleasant but rather insipid flavor. *Prunus tomentosa* is perfectly hardy; and its neat habit, handsome foliage, early flowers and showy fruit, entitle it to more general use along the margins of shrubberies or in the borders of small gardens.

Lonicera Standishii and *L. fragrantissima* are in bloom. These are probably forms of the same species. The branches of the former are scabrous, however, and the leaves are deciduous, while in *L. fragrantissima* they are almost evergreen. Both plants produce large, nearly white, deliciously fragrant flowers before the appearance of the new leaves. They are tall, stout, twiggy shrubs, with flexuous pale yellow-brown branches, and oblong acuminate leaves, three to five inches long. They are both doubtless of Chinese origin, although *L. fragrantissima* is a common garden plant in Japan. *L. Standishii* is by far the hardier of the two here, and this fact and its deciduous leaves point to a more northern origin. It was introduced into England by Fortune, the Chinese traveler, who found it a common garden plant at Shanghai. Neither of these plants are very hardy here, but splendid specimens of Fortune's plant are a conspicuous feature in the shrubberies of the Central Park in New York during the last days of April.

A dwarf variety of the common Leather-leaf (*Cassandra calyculata*), sent to the Arboretum by the Messrs. Veitch, is in bloom fully ten days earlier than the American plant. It is a compact and handsome shrub, eight or ten inches high, and well worth a place in any garden border. And this is true of *Myrica Gale*, which, although a denizen of the borders of ponds and deep, cold, submerged northern swamps, is perfectly at home here on a dry, gravelly and exposed ridge, where it has been flowering profusely during the past week. The Sweet Gale is a handsome and very fragrant deciduous shrub, three to five feet high, with pale wedge-lanceolate leaves, appearing later than the flowers, which are produced in stout, dense, chestnut-brown catkins from the upper axils of the branches. It is a native of the northern Atlantic States of northern Europe and of Siberia.

Salix chlorophylla, a low spreading bush, a few inches high, from the Alpine summits of the White Mountains of New Hampshire and from British America, takes kindly to cultivation, and has been in flower for a fortnight. It will make a useful plant for the margins of shrubberies, where a bright, pleasant green is desired rather than conspicuous flowers. Two other North American shrubs, now in bloom, can be used with great advantage for the same purpose. They are the shrub Yellow Root (*Zanthorhiza apiifolia*), a member of the Crowfoot Family, and the fragrant Sumach (*Rhus aromatica*). The *Zanthorhiza* inhabits the shady banks of streams in the Allegheny Mountains. It is a low and very hardy shrub, with

erect stems twelve to eighteen inches high. The flowers are small, polygamous, brownish purple, and arranged in short, compound drooping racemes, which appear with or just before the pinnate leaves from large terminal buds. The plant spreads rapidly by the development of stems from the stout roots, which, as well as the bark, are intensely yellow and very bitter. It is a free-growing plant in cultivation and an excellent dwarf under-shrub, easily increased from seed or by division. The Fragrant Sumach is one of the best plants, if not the very best, to connect, in this climate, a mass of larger shrubs, with the turf of a lawn. It is low and spreading and feathers out over the grass in pleasant, irregular masses of pale green, and is never obtrusive with flowers too conspicuous for such situations, or with inharmoniously colored foliage. The minute yellow polygamo-dioecious flowers, in clustered catkin-like spikes, precede the leaves, which are trifoliate, pubescent when young, thicker and almost coriaceous at maturity, the leaflets unequally cut toothed, the middle one wedge-shaped at the base. They are fragrant when crushed. *Rhus aromatica* is a native of the northern and north-western States, where it inhabits dry, rocky hillsides. It flourishes in any garden soil, and can be easily propagated by layers, or from seed, which is very sparingly produced and not easy to obtain. The leaves in autumn are brilliantly colored in orange and scarlet. This plant is too little known and appreciated in gardens.

The leafless branches of the Spice-bush (*Lindera Benzoin*) are covered with dense compound clusters of bright yellow flowers. This is a tall and pungently fragrant shrub, which is easily cultivated, and recalls, at a little distance, the European Cornelian Cherry (*Cornus mascula*). Its early flowers brighten low, damp woods and pond sides through the Northern States.

Andromeda floribunda, one of the hardiest of the broad-leaved evergreens peculiar to the Allegheny Mountains, is loaded with racemes of pure white, handsome flowers. It is a desirable plant, which forms in cultivation a dense, leafy shrub, four or five feet high, and which will grow in nearly all soils and exposures. A slight covering in winter of evergreen boughs protects it from burning, and is of general advantage to the plant, and this is true, in this climate, of nearly all broad-leaved evergreens.

The Mayflower or Trailing Arbutus (*Epigæa repens*) is now well established in the Arboretum, and is in full flower—almost ten days later, however, than in the woods at Plymouth, where it abounds. It is a prostrate, trailing and scarcely woody plant, with evergreen, rounded, reticulated leaves and deliciously fragrant, rose colored flowers in small axillary clusters. It is the best known and most popular wild flower of New England, and efforts to cultivate it are often made. The Mayflower, however, is extremely impatient of confinement and can be naturalized in new localities only with the greatest care. Young plants (it is useless to try to transplant old plants) should be taken up late in September or in October, and carefully potted or planted in shallow boxes, in a compost of sandy peat, and then kept in a close atmosphere in a green-house or frame until new roots are formed. The plants can then be wintered in a cold pit, but should not be planted out until the second spring, by which time they will be strong and vigorous and able to take care of themselves. They will do best if planted on the north side of a hill in a compost of rather light sandy soil mixed with leaf mould. When once it has a firm hold of the soil, the *Epigæa* will spread rapidly, and will repay the labor necessary to establish it. J.

May 7th.

The Forest.

The Pennsylvania Forestry Association.

THE annual meeting of this active society was held in Philadelphia on the evening of May 3d, with Burnett Landreth in the chair. The first address was by Dr. N. H. Egleston, of the Department of Agriculture, on the æsthetics of tree culture. Mr. J. B. Harrison was the next speaker, and after a cordial allusion to the poetic beauty of the address which had preceded his own, he said, in substance:

"Our chief interest in forestry is, of course, in the preservation and reproduction of trees for the most common uses, and we have to deal with large masses of forest in their relation to the water supply of vast areas of country, and with forestry in detail, in the case of woodlands in the hands of individual citizens. It is encouraging to see so many people drawn together

by interest in this subject. I recall the years of lonely effort in this field, when the only forestry meetings were held when two or three pioneers met to compare notes of their observations, and consult regarding plans for arousing public attention to the rapid destruction of the forests in every part of our country. There has been considerable discussion of forestry subjects within the last few years, but the practical results achieved, in the preservation of our forests, are, thus far, very slight.

"The Adirondack mountain region in northern New York is by far—or it *was* a few years ago—the most important body of forest lands in the eastern portion of our country. But these magnificent woods have now been for several years in process of rapid extinction. There was a well equipped Forest Commission in New York a few years ago, the most competent, indeed, that has yet been appointed in any State of our country, and this Commission made a thorough examination of the condition of every part of the great North Woods, and reported a plan which, if it had been adopted by the State, and administered in good faith, would have stopped the progress of ruin and desolation, insured the preservation of most of what at that time remained of the original Adirondack forests. But there was sufficient ignorance, indifference, apathy and other unfavorable influences, even in New York, to defeat this carefully matured plan. Vested interests and partisan political considerations, working together in defense of existing methods of mismanagement, were too strong to be overcome by the friends of the forests, and the process of destruction has gone on with little check until now. I know of but two or three men who have any just idea of the extent and thoroughness of the ruin which has been wrought in northern New York. But lumbermen who have known the Hudson River for forty years say that the summer flow of that stream has diminished one-fourth or one-third during that time. The railroad people are completing arrangements for the destruction of most of the woods which now remain in that region, and efforts are being made to obtain legislation which will permit the leasing of tracts of State forest lands to rich men from the towns. It would be hard to devise a more unreasonable or mischievous measure. It ought to be promptly condemned by the people of the Empire State.

"The destruction of the woods goes on in nearly every part of our country in much the same way. I have observed the work of the tree-slaughterers in the turpentine forests of our southern Atlantic States, and have watched the work of railroads and lumbermen, and of forest fires, in the great mountain forest regions of the West. I have studied the magnificent forests along Puget Sound and in the Cascade Range through Washington Territory and Oregon. The forest masses in every part of our country are being rapidly and inevitably destroyed. As they perish the water-supply for the great river systems of the country is diminishing, and vast territories are exposed to the evils of destructive floods and exhaustive drought.

"The question of methods for the preservation of our great forests is one of exceeding difficulty, and the chief obstacles are psychological—that is, they are found, not in any feature or circumstance of the condition of the forests themselves, but in the habits and qualities of mind, thought and character of the American people. As a nation we are much disposed to an excessive reliance upon legislation as a means for the attainment of nearly all objects which we regard as desirable. The fact is that it is comparatively easy to obtain almost any imaginable legislation. But law alone, in relation to any subject so complex as the preservation of our forests, is of very slight value. No act of Congress, or of a State Legislature, can have much effect in changing the habitual course of thought, feeling and action in the mass of the people of our country. But precisely such a change is indispensable, if our forests are to be preserved.

"The truth is that nothing short of an advance in civilization on the part of the American people would be sufficient to stop the process of forest destruction which is now everywhere going on. The wisest forest laws would inevitably be administered very ineffectively at first. Many mistakes would be made, and if we have to depend chiefly upon the effect of legislation for the preservation of our forests, it is most probable that by the time we have learned how to take care of our forests efficiently we shall have none remaining to take care of. To prepare us for the wise care of the varied and widely related interests which depend upon our forests we need important and radical changes in the thought and spirit and character of our people. While the popular feeling about wealth, about *bric-a-brac*, about the objects of life remains what it is, the destruction of our forests, and of all that depends upon them, is likely to proceed unchecked.

"I talked with a farmer in south-western Iowa last summer who has cut off thousands of Black Walnut trees from ten to fifteen inches in diameter, during the last thirty-five years, and sold them for cord-wood. I showed him price-lists for black walnut lumber and veneers from New York dealers, and easily convinced him that if he had let his walnut timber stand till now it alone would be worth far more than his whole farm is now worth. He said he had no doubt it was true. Then he added, 'But it is too much trouble to think of anything so far ahead.' That is the key to many things in our national character.

"In our thought of the supreme value of legislation for forest preservation and reproduction we are beginning at the wrong end of the business, and are putting that first which should be last. A long course of education of the people regarding the facts of the subject will be necessary before adequate legislation can be devised or efficiently applied. What we chiefly need now is an era of teaching and instruction regarding the subject—teaching that shall be intelligent and intelligible, comprehensive, coherent, systematic, iterant and authoritative, because based upon competent knowledge. The greatest step in advance ever taken in this country in connection with forestry subjects has been made this year, in the establishment, in New York, of a journal devoted to the discussion of forestry in all its aspects, and to the dissemination of knowledge in relation to this subject.

"Europe, and every other part of the old world, can give us all needed lessons of warning; can show us the tragical consequences of man's want of wisdom, care and foresight in his treatment of the forests in every land. But even for these lessons we do not need to cross the ocean. We already have created small deserts in various parts of our own country, where the area of desolation and of cureless ruin grows larger every year. I remember places where the drifting sand is steadily swallowing more and more of the once fertile slopes where a century ago the White Pine grew four feet in diameter.

"I do not think, however, that Europe can give us much help as to methods of forest care or management. The psychological conditions are so very different here, that we shall have to learn our own lessons by our own observation and study and experience. Our social and political conditions are essentially different from those of any European nation. So are the relations of capital to the mass of the people. I have no doubt that in time we shall evolve American methods of forest management. The best means to that very desirable end must be vigorous, free, intelligent and persistent discussion."

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—Any one acquainted with the southern side of Long Island will readily recall the vast stretches of low land fringing the borders of the various bays for which that part of the coast is noted. Its only use, apparently, is to furnish a little salt hay; but it has often occurred to me that there might be some tree which would grow in such situations, and be worth planting there. Has anything ever been tried in these dreary wastes, and with what success? If not, what would you recommend for trial? It goes without saying that if only some arborescent growths could flourish in such spots where the soil must be saturated with water more or less saline, the land would in time become very valuable.

I believe there have been some interesting and successful experiments in improving low sandy wastes along the coasts of New England and New Jersey, but I never heard of any attempts to reclaim the marshy borders of our great salt-water bays. Very truly yours,

New York, May 1st, 1888.

A. Z.

[No tree hardy in the Northern States will grow in saline soil or in situations where its roots reach salt water. The salt-marshes, which are so common along the north Atlantic Coast, are really valuable for the hay they produce. This crop in some parts of New England is estimated to yield six dollars a year net per acre; and marsh land finds a ready market at \$100 an acre. Such land is too valuable, therefore, to plant with trees even if trees could be made to grow on it. The low, rolling, sandy hills so common at some points on the south shore of Long Island might be planted to advantage with Pitch Pine (*P. rigida*) in the same manner that similar land on Cape Cod has been covered with this tree.—ED.]

Pictures of Japan.

AN interesting collection of pictures of scenes in Japan was recently exhibited in the Reichard gallery on Fifth Avenue. The painter, Mr. Theodore Wores, is a young Californian, who, after completing his studies at Munich, passed three years in Japan and is now established in a New York studio. Some of his pictures represented street-life in the Island-empire or works of architecture, but many dealt with themes of exceptional attraction to lovers of flowers and students of gardening art. In one, for example, we saw a long avenue of pink-blossoming Plum-trees, with a couple of young girls examining the strips of paper, inscribed with impromptu verses, which, in accordance with a pretty national custom, are frequently hung on these favorite trees when they are in flower and the people go in thousands to enjoy them. The wide road, which for the moment wore the aspect of a great flowery arbor, had an open space in the centre wide enough for the passage of the small vehicles of the country and then on either side a line of oval stones sufficiently raised to give comfortable footing in wet weather. Another canvas showed two young girls in a jinriksha, bringing home great branches of the double-flowering pink Cherry, and on more than one we saw large trees of this species in full bloom, in front of tea-house or temple. Another showed the balcony of a tea-house overhanging a pond in which floated great golden carp, and overhung itself by an immense Wistaria-vine, with clusters of flowers, such as are not uncommon in Japan, fully three feet in length. Another had as the foreground a Japanese room, the widely open side of which gave an enchanting glimpse of a garden with miniature streams and bridges, and, in front of a small building, a large tree with smooth light-colored bark and coral-colored blossoms, called in Japan *Sarosse-souberi*—the Indian Crape Myrtle (*Lagerstroemia Indica*). A glimpse of a garden at Nikko, with a tiny cascade overhung by a Weeping Willow, was also interesting; but the most attractive of all the pictures to a lover of artistic floral arrangements was the one called "A Lotus Pond." The pond formed part, apparently, of a large park, and was itself a rectangular basin, perhaps sixty or seventy feet in diameter, filled by a thick, tall growth of pink Lotus. It was enclosed by a well-built stone wall crowned with a simple yet dignified stone balustrade. Large rectangular posts finished with ball-like ornaments and widely spaced, were the chief supports of a plain rectangular rail, while the many lesser intermediate supports were diamond-shaped on plan and set anglewise to the road. Where the water of the pond flowed off in a little stream the road was carried over an arched bridge of graceful low curve, and the balustrade here became a solid paneled parapet, sparsely ornamented with carving. Nothing better could be found for imitation in this country than this balustrade and bridge, and many lessons in the designing of wooden railings might also be gathered from Mr. Wores's pictures. When used in connection with much foliage they appear to be generally painted of a soft pale green, lighter than the green of the foliage but harmonious with it, having nothing of that crude, acid tinge which our own green pigments so often show. And in all cases the uprights were plain and far apart, and less conspicuous in effect than the three or four horizontal members. The contrary is usually the case in our own wooden fences, but a comparison of their trivial, fragile appearance with the simple solidity of these Japanese fences would convince any eye that we should do well to change our practice.

It was interesting to note in one of Mr. Wores's street-scenes how the artistic instincts of the Japanese display themselves even in the humblest and simplest articles of utility. The chief figure in the scene was an itinerant flower-vendor, and his wares were carried, not in baskets, but in two great open cages of bamboo, to the uprights and cross pieces of which were attached hollow sections of bamboo, some large and some quite small, in which the flowers were placed—always in bunches of a single sort. The whole arrangement was light, portable and altogether practical, yet as pleasing to the eye as though beauty had been the sole end in view.

M. G. van Rensselaer.

The Boston Flower Show.

The May exhibition of the Massachusetts Horticultural Society held on the 12th inst. was far richer than was expected, not only in plants competing for prizes, but in the variety and excellence of other contributions. Among the most noticeable plants was a magnificent pyramidal specimen of the Indian *Azalea decora* nearly eight feet high from Mr. J. L. Gardener, for

which he was awarded a silver medal. Denys Zirngiebel exhibited several dishes of the best strain of Pansies ever shown in this country. The flowers were more than three inches in diameter, of good form and substance, and the colors cannot be described. Some were a genuine red, while others had almost all imaginable colors blended together. The committee justly awarded a silver medal for those beauties. Good plants of Calceolarias were shown by Thomas Clark and W. Spencer, and in the first collection was a plant with two-lipped flowers which seems quite desirable. Some fine Pelargoniums were sent by W. Martin, gardener of N. T. Kidder, Esq., and some by J. H. White, who also showed some good Gloxinias. Mr. W. Spencer exhibited well grown plants of *Cattleya Skinneri*, *Cattleya Mossia* and *Anguloa Clovesii*, while Mr. Martin staged a fine plant of *Dendrobium thyrsiflorum* with eight spikes, *Cypripedium Lawrenceanum* and *C. barbatum*. Mrs. P. D. Richards showed a very instructive collection of named native plants. The display of cut flowers was very attractive.

Retail Flower Markets.

NEW YORK, May 19th.

There are complaints of dullness of trade throughout the city. Flowers are plentiful, but the average quality of them is not satisfactory. Hybrid Roses are short-stemmed as a rule. American Beauty, Magna Charta and Baroness Rothschild are the Roses arriving in the finest condition. Ulrich Brunner is also very handsome. Long-stemmed flowers of the above varieties bring 75 cts. each. General Jacqueminots are small and scarce. The best cost \$3 a dozen. Countess of Pembroke and La France sell for \$2.50 a dozen. Madame Cuisin, Bride and Catherine Mermets cost \$2 a dozen. Moss Rosebuds are esteemed the choicest of the Rose stock. These are \$5 a dozen. Puritan Roses are \$4 and \$6 a dozen. Perles, Niphetos and Souvenir d'Un Ami are \$1.50 a dozen. Papa Gontiers and Bon Silenes are 75 cts. a dozen. Carnations are 50 cts. a dozen. Southern Lilacs have disappeared, and this flower is scarce; although a few come from New Jersey. Violets are virtually out of market. Pansies are very handsome, and 25 cts. a dozen. Dutch Hyacinths are \$2 a dozen, but are in slow demand. Tulips are 50 and 75 cts. a dozen. Daffodils do not drop below 75 cts. a dozen, and Lilies-of-the-Valley are disposed of easily at \$1 a dozen if well grown. Mignonette is 25 and 50 cts. a dozen. The large spiral sorts have disappeared. *Narcissus poeticus* costs 75 cts. a dozen, and Gardenias are \$3. Callas bring \$3 a dozen, and Gladioluses the same. Orchids are much used for dinner decorations. Cattleyas are the favorite variety. They cost 50 cts. a flower.

PHILADELPHIA, May 19th.

The only novelties worthy of mention that have appeared this week are single Dahlias and Gladioluses. Single Dahlias are admirable for cut-flower purposes; they sell at \$3 a dozen. Gardenias are more plentiful, and sell at \$2.50 per dozen. Roses in general are not so good in quality. Catherine Mermets, Brides, Bennetts and La France sell at \$2 a dozen. Perles and Sunsets from \$1 to \$1.50. Niphetos and Papa Gontier, \$1; Bon Silene, 75 cts.; Madame Cuisin, \$1.50; Madame Gabriel Luizet, \$3 to \$4. These retain their delicate coloring, but are falling off in size. Baroness Rothschild's are \$3. Jacqueminots, \$1.50 to \$2.50. American Beauty rules higher in price than any other Rose now offered—quotations are from \$3 to \$5, choice flowers selling readily at the latter figure. Tulips range from 50 cts. to \$1—the fine late varieties selling at the highest price. Carnations and Mignonettes 35 cts., and Pansies, 25 cts. a dozen. Lilacs sell on the street corners as low as 10 cts. a bunch of ten sprays. Apple and Cherry blossoms are occasionally offered at 10 cts. a bunch. The Maidenhair Fern (*Adiantum concinnum*) sells at 35 cts. a dozen fronds. It is used largely in plateaus, with the living plants plunged in Moss; in this way they remain fresh for a long time. Gladiolus in limited quantities sells at 25 cts. a spike.

BOSTON, May 19th.

The week of rainy weather, so beneficial to all out-door vegetation, has had an opposite effect on hot-house productions, particularly Roses. The Roses coming to the market at present show plainly the influence of the damp, dark weather. Catherine Mermets are decidedly off color. The same is true of Bon Silene and La France. Jacqueminots are scarce and Hybrids generally almost unobtainable. Roses of the small Tea classes sell for 75 cts. per dozen. Fancy Teas, \$1.50 to \$2.00, and Jacqueminots at \$4.00 to \$5.00 a dozen. Carnations are more abundant and of better quality; 50 cts. a dozen is the ruling price for long stemmed blooms. Lilies-of-the-Valley, Tulips and Narcissus grown out-of-doors, are beginning to come in. They bring from 50 cts. to 75 cts. a dozen. Ascension Lilies are still in good supply at \$1.00 a dozen, while \$2.00 is asked for *L. longiflorum*. There is an abundance of white Stocks in market at present. The quality is of the best, and although somewhat coarse, yet their delicious fragrance makes them a welcome addition to assorted boxes of cut flowers. It is fortunate that spring flowers are popular, as there are but few very choice varieties offered. Marguerites, Pansies, Mignonette, Heliotrope, and such small flowers are abundant and very cheap. Maidenhair Ferns are now of best quality. Smilax still rather scarce.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, MAY 30, 1888.

An Important Literature.

THE admirable report of the Connecticut State Board of Agriculture for last year, which has just been received at this office, calls to mind the rapidity with which literature of this sort is accumulating. Many of these volumes contain papers of permanent value, prepared by experts in various lines of investigation, in all departments of practical agriculture, horticulture and forestry, and in the sciences related to them. Besides these, many of the states publish reports of horticultural societies, of experiment stations, of forestry meetings and of official entomologists and botanists. To these official documents issued by the state must be added the publications of viticultural associations and of a national association of horticulturists, one of nurserymen, another of florists, and another of seedsmen, not to mention the reports of the venerable American Pomological Society. In Wisconsin, where a thoroughly organized and competently conducted system of farmers' institutes is held every year, the cream of the discussions, covering the entire range of rural economy, is gathered into an interesting volume and issued at public expense. Every year the number of these publications increases, and they keep pace in quality with the advancing intelligence of their readers on all the subjects treated. Most of them are published in large editions, which are distributed gratuitously, so that almost any one who may desire to do so can collect a good-sized library on practical horticulture and agriculture at a trifling cost.

Of course the various papers in these publications are of unequal value, and the secretaries do not always edit them as carefully as they would if the books were sold on their merits. This means that much chaff is included with the wheat, and at times the reader grows weary, and wishes that the winnowing had been done for him. Very plainly the value of these official documents could be increased and their expense diminished if their contents were more carefully selected. This evil increases as the volumes multiply, and unless some heroic reform is soon begun, the articles of real value will be buried at last under such a

mass of inferior matter that they will be practically lost. And this difficulty is increased by a lack of proper indexing. The compilers are not paid adequately for the work of careful editing and complete indexing, so that the student finds what he most wants only by laborious searching or by lucky accidents.

The increase of experiment stations under the law creating one in every state, and the fact that periodical bulletins are required from all of them under the statute, will swell the volume of this literature until it literally burdens the mails, inasmuch as it enjoys the rare privilege of being carried without postage. Perhaps the first froschet of these bulletins will have small value. Very little work of genuine worth can reasonably be expected of an experiment station before there has been time and adequate preparation for experiments. It may be added that little instruction can be looked for from these institutions unless they are officered and manned by skilled observers, trained to habitual accuracy. Indeed, it is not improbable that crude teachings, advanced with the presumption and assurance that always accompany superficial work, may in occasional instances do more harm than good. It is too evident that until there are in this country more men of scientific training who are available for work of this kind, the stations will be inefficiently conducted. It must be assumed, on the other hand, that the work, and as a consequence the publications of these stations, will rise in value until they contain each year a body of doctrine that cannot be neglected by students or by practical tillers of the soil. The obvious suggestion is that at some office of central authority these current reports should be collected, collated and classified.

A periodical statement in condensed form of the conclusions reached at the various stations, if it were accurate and authoritative, could not fail of being useful. For popular reading it should be translated as far as possible into simple language and should be unencumbered with technical details; it should be edited and annotated in such a way that ordinary readers could distinguish and separate what had been actually proved from what was only probable or still in controversy, and the practical bearing of the scientific investigations recorded should be plainly set forth. At a meeting of representatives of the various agricultural colleges and experiment stations held last October, the necessity of some co-ordination of effort among these institutions appeared so evident, that a committee was appointed to consider this among other subjects; but so far as we are advised, no plan for editing the bulletins has been perfected.

The national Department of Agriculture is the natural place where a compilation of this kind should be prepared in connection with the work of its own divisions of chemistry, entomology, pomology, botany, forestry, and mycology. The Commissioner himself should be a man of recognized scientific attainment, or at least he should have such a known appreciation of the value of special training that he would be selected without question as the proper person to organize this bureau for gathering up the scattered and incomplete work of the state stations, for systematizing and unifying it, and for publishing its results in a coherent form. Unfortunately the men who have filled this office could not always be trusted to supervise a labor of this sort; but perhaps the influences which have impelled Congress to create the stations may avail to secure hereafter the selection of a chief who will be accepted by all as equal to every duty imposed upon him. Meanwhile the horticultural, agricultural and other reports are multiplying, and they already contain many papers that students would like to read if they only knew where to find them. Would it be a work unworthy of the Department to have made a full, topical index of all these reports up to date? It would seem that the stores of experience locked up in these volumes was worth enough to justify the trouble of providing a key. Such an index could not fail of being helpful to every one engaged in special research in any direction and in any portion of the field of agriculture, horticulture or forestry.

Balcony Flower Boxes.

A LARGE number of the dwelling-houses in our smaller towns stand far enough apart from one another and far enough back from the street to be encircled by small lawns, by trees and shrubs and flowers. If their owners do not always make the best possible use of the opportunities thus afforded them, still there are few cases in which some desire for beauty is not manifest; and the general aspect of streets composed of such houses is apt, at least, to be verdant and cheerful. But in every town which deserves the name—which is too large to be called a village—we find other streets where the houses stand so close together and so near the street, that, except as they may have yards lying in the rear, no space for gardening remains. The aspect of such streets as these is too commonly dreary and dull in the extreme. The architectural interest, or, at least, dignity, which the streets of a city may have is wanting; and, although a row of Maples may shade the sidewalk, there is nothing to show that the householder has any love for natural beauty or any wish to enliven the prospect for himself and his neighbors. Yet this householder is most often of the class which cannot seek beauty and refreshment by prolonged summer vacations in really rural spots. Winter and summer his home must be here, and it seems a double pity, therefore, that there should be so little to mark to his eyes the difference between the seasons. Surely something might be done to enliven such streets a little, and to give their occupants a small taste of the pleasure which their wealthier neighbors get from their lawns and shrubberies and flower beds.

The only available resource is the cultivation of plants in boxes. But simple and humble though it sounds, it is a resource in which lie possibilities of great improvement for such streets as we have in mind, and of much enjoyment for their dwellers. A few years ago a lady who had lived long in Germany, where the growing of plants in window-boxes is a widespread national custom, found herself established for the summer in the central house of a row of small, ugly wooden houses in a little town near New York. The front stoop descended to the sidewalk, and between the parlor windows and the front railing there was room for nothing more than a narrow balcony and an exiguous strip of grass. But before the summer was over this naked, unattractive house-front was blossoming like a bower. A few Roses had been planted in the narrow strip of grass, a few creepers beside the stoop; from the roof of the porch hung a great basket of trailing plants, and along the top of the balcony balustrade ran wide boxes filled with veritable little thickets of foliage and flowers. The cost had been almost nothing; the labor bestowed had been little indeed; but the result was charming, and the succeeding season bore good results. Not only had many neighbors followed the example thus set, but here and there all through the town could be seen attempts at imitation. Balconies were encircled with flowery boxes, window-sills were filled with them, and even the railings of long piazzas bore them too.

Boxes suitable for such purposes can be made at the most trifling expense of pine-wood, painted to correspond with the house. If the support on which they stand is narrow, additional space may be gained by flaring their sides. Holes for drainage should be pierced in their sides near the bottom, and they should have a layer of potsherds or small stones beneath the rich garden-earth with which they are filled. If the space exceeds five or six feet in length, it is better to use a succession of boxes instead of one long one, as then they may be more easily emptied and removed at the coming of winter, to be kept in a dry place until again required. Plant towards the front of the box such trailers and creepers as will grow to five or six feet, but not more, in length—German Ivy, for example, Tradescantia, Cypress-vine, and, among them plants of Lobelia, Mahernia and the pretty little Convolvulus which seedsmen call *C. minor*. And behind these, which

after a very few weeks will form a deep curtain of waving green across the front of the balcony, plant what you will so long as it will not grow to too great a height nor form too solid a mass of color. What you want is not a mass of vivid Coleus nor of pink and red Geraniums, but a mass of green, with here and there a Geranium or Verbena, or a crimson Coleus and sparks and accents of all bright hues. Not only are the effects thus produced more beautiful, but the danger from thievish boys is less than when a mass of easily picked large flowers attracts their fingers.

Many of the most desirable plants for this purpose can be grown from seed, and the others can be very cheaply bought in pots. The care they require will not extend beyond a gradual thinning out as growth progresses, a little attention to the direction of the trailing shoots, a constant removal of faded flowers, and a daily watering—all of which can be done at odd moments, and with none of the fatigue that attends stooping over garden-beds. For this last reason the cultivation of such tiny box-gardens should be especially attractive to invalids and elderly persons while the beauty they may be made to yield will be doubly valued for being constantly under the eye of those whom household cares keep much within walls.

An appropriation for the establishment and maintenance of a Forestry Station at Dodge City, on the Arkansas River, in the extreme south-western part of Kansas, was made by the last Legislature of that State. Mr. George V. Bartlett, of Ohio, has been appointed director of the Station. Fifty acres of ground, previously prepared by a season's cultivation, has already been planted with the seeds of a great variety of trees, and large numbers of forest and fruit trees have been planted. The results of such experiments, if properly conducted, made in a region where the annual rainfall is insufficient to secure a natural growth of trees, cannot fail to be interesting and valuable. If trees can be made to flourish permanently at Dodge City, without the aid of irrigation, the important facts will be demonstrated that cultivation can be depended on to take, to a certain extent, the place of rain, and that trees, if properly cared for, can be induced to grow in regions which are naturally treeless, owing to natural conditions unfavorable to tree growth. On the other hand, if the trees planted at Dodge City are unable to support the aridity of the Plains, these experiments should go far to prove that a large part of the naturally treeless region in the interior of this Continent must, even under favorable conditions of cultivation, remain forever treeless. Mr. Bartlett has a problem to solve of great public importance, and the results of his experiments will be watched with interest.

Climate of the Prairies.

IN a paper read before the American Pomological Society at Grand Rapids, Michigan, on "Hard Problems in Pomology," I said: "Year after year since 1856-7 our lists of fruits, shrubs and trees for general culture have been revised by the active horticultural societies of the Prairie-States, yet to-day the northern half of Iowa and Illinois, and the southern half of Minnesota and Wisconsin, can show more dead or crippled trees and shrubs than has been known in the world's history at any one time."

The real causes of this general wreck of trees and shrubs listed as "hardy" east of the lakes do not seem to be well understood. The common impression at the east seems to be that our orchard troubles are caused by winters far more severe than are known in any part of New York.

In reality our mid-continental extremes of heat and moisture of air during summer and autumn have most to do with the health and longevity of our ligneous plants. When our first settlers built their cabins on the borders of our isolated groves and river timber-belts, they could not fail to notice the absence of the Mosses, the Laurels, the Rhododendrons, the Conifers, and the plants generally of

more humid and equable climates, and they soon learned that our extremes of moisture and temperature presented new problems in plant and tree culture.

As early as 1856-7 the stories of dead and dying trees were told over a large part of the west, but a careful comparison of notes will show that many varieties of the orchard-fruits, and of ornamental trees and shrubs, which endured perfectly the extremes of rainfall and of atmospheric changes in the early days, are now placed in the tender list. The reasons for this apparent increase of climatic rigors of which our early settlers complained is beyond all doubt due to changes wrought by man.

As stated by Bryant in his work on Forest Trees, the primitive prairies were covered with so dense a growth of grass, that on the lower levels it could be tied over the head of a man sitting on horseback, while sloughs, marshes and drainage-centres were clogged, and the primitive timber of the streams presented real forest conditions. The whole country was in condition to hold the June rains and give them off gradually to the summer air.

At that time we were subject to variations of rainfall ranging from 74½ inches in 1851, to 23½ inches in 1854, but the prevailing westerly winds of such dry seasons as that of 1854 were never known to "fire" the blades of corn, to curl and burn the leaves of fruit trees, or to prevent the deposit of copious dews at night, as they passed over a vast stretch of clothed plain that modified the intensity of their heat, and left a part of the moisture they contained.

Since that time man has wrought changes in the whole aspect of the country.

A section large enough to make several such kingdoms as are found in western Europe has been turned with the plow, the surfaces of sloughs and marshes have been bared by clearing away the timber and hardened by drainage. During the droughts of 1886 and 1887, our prevailing winds from the west and south-west during the growing season have passed over a relatively dry, heated plain which has drunk up their moisture with avidity and raised their temperature to a degree not known thirty years ago.

Possibly these climatic evils, as Bryant says, may be "mitigated and perhaps wholly removed by planting a due proportion of the country to forest trees," but in the meantime we cannot wonder that we cannot grow some of the field crops and many of the varieties and species of trees and shrubs that thrived with us thirty years ago. Yet eastern readers must not get the impression that we have an approach to desert conditions. The extreme seasons we speak of, with light rainfall, extreme heat and aridity of air, followed by cold dry winters, that are so fatal to the larger part of the orchard fruits, ornamental trees and shrubs grown at the east, visit us at rare intervals and do not materially affect our agricultural interests when the general results of periods of from five to ten years are considered.

And even these extreme years permit almost perfect success in growing the small fruits, the grapes, our native plums, and such orchard-fruits as can endure the extremes of heat, aridity, and temperature of our summer and winter climate, as well as our native forest trees.

We succeed with the small fruits, the grape and the plum because they are native to our soil and climate. We fail to grow successfully the small fruits, grapes, apples, pears, cherries, forest trees, ornamental trees, shrubs, etc., of western Europe, and their seedlings originated in the States east of us, for the reason that in leaf, bark, and character of cell structure of wood they do not meet our climatic requirements.

But all this does not prove that in due time we shall not conquer the situation by the introduction of the orchard fruits of climates similar to our own.

We have already a great number of varieties that stand every extreme as well as our Box Elder. If with farther trial they do not come up to our standard of excellence in quality, we can rapidly change them by crossing and

by selection. We may not materially modify our climate, but we can and shall adapt plants and trees to it as has been done in similar climates of the old world. At another time I will attempt to give some of the peculiarities of leaf, bud, bark and wood, of the ligneous plants that bid defiance to prairie-winds and weather.

J. L. Budd.

Fungus Diseases of Insects.

IF the subject of injuries done by insects to plants of various kinds is of interest to horticulturists, it is, as a matter of course, interesting to know about the fungus parasites which destroy the insects themselves. Every one has noticed the white fungus which attacks and kills large numbers of house-flies in the summer and autumn. A good deal has been written on this fungus in a popular way, and its specific name, *Empusa muscæ*, is probably not unfamiliar to many of our readers. The species belongs to the order *Entomophthorææ*, which has been but little studied in this country, and an admirable monograph on the subject, by Mr. Roland Thaxter, published in the Memoirs of the Boston Society of Natural History, contains a great many facts of interest even to those who are not in the strict sense botanists.

Only three species of *Empusa* had been known hitherto in the United States: *Empusa Muscæ*, which kills house-flies; *E. Grylli*, which causes epidemics in grasshoppers; and *E. sphaerosperma*, on the clover-leaf weevil. Mr. Thaxter describes 26 species of *Empusa* in the United States, 15 of which are new to science, and, so far as yet known, peculiar to this country, and 8 which occur in Europe, but not before recognized here. The insects attacked were species of several orders, flies, gnats and other *Diptera* being most frequently, and *Neuroptera* (dragon-flies) the least frequently affected. Besides the species of *Empusa*, Mr. Thaxter gives descriptions of a related form previously known on the seventeen-year locust, and a curious form on the excrement of frogs, not before found in this country.

The *Empusæ* have two forms of reproductive bodies, some found on the surface of the insects attacked and others in their internal organs. The nature of the latter has not been very well understood, but the facts stated by Mr. Thaxter form an important supplement to what has previously been written on this point, and it is now plain that this group of insectivorous fungi should be classed not with the white moulds which produce disease in fishes, such as the salmon mould, but rather with the common moulds which flourish on various articles of food in all houses. The discovery of so large a number of fungi of the genus *Empusa* which attack a surprisingly large number of species of insects, and the accurate knowledge of their habits and mode of reproduction, recently obtained, would lead us to believe that, at no very distant day, it may perhaps be possible to check the increase of some injurious insects by artificial propagation of the *Empusa* which prey upon them, and, under suitable conditions, destroy them.

W. G. Farlow.

Foreign Correspondence.

London Letter.

THE most valuable Orchid which received a certificate at an April meeting of the Royal Horticultural Society, was a variety of *Odontoglossum crispum*, from Mr. Charlesworth, an importer at Bradford. It has very large and finely shaped flowers, the petals and sepals exquisitely crisped and almost wholly covered with bright reddish brown blotches. It is the finest variety that has been exhibited this year, and will take equal rank with *Veitchianum*, *Sanderianum* and others. It is known as Charlesworth's variety. An Orchid somewhat similar to the striking *Odontoglossum Rossii*, var. F. L. Ames, already described, is *O. Humeanum*. It is supposed to be a natural hybrid between *O. cordatum* and

O. Rossii, and was considered worthy of a certificate, inasmuch as it is pretty and distinct from other varieties. It does not differ much in growth from the typical *O. Rossii*, but the form of the flowers and their color is different, the lateral sepals being a pale lemon yellow, with reddish brown blotches at the base, the other sepals coffee-brown, the lip pale yellow, crest yellow, and column purple. It is a good deal like one called *O. aspersum*, and, in fact, may prove identical with it. Though not a new Orchid, *Angraecum arcuatum* received a certificate, apparently because of its rarity. It cannot be called a first-rate Orchid, many species of *Angraecum* being much more showy. Its flowers are white, borne in short spikes and sweetly scented. It is quite a specialist's plant, and certainly did not merit a certificate in comparison with the others shown. The greatest novelty among Cattleyas that has been seen this year is a form of *C. Trianae* named *Courtauldiana*. It is a good deal in the way of Backhouse's variety, but more remarkable. The flowers are above the average size and of good form. The sepals and petals are pale pink, heavily barred with the richest carmine crimson down the centre of each petal; but the bars are made up of freckles and spots, and not of one heavy dash, as in Backhouse's variety. The lip, too, is very rich in color, so that altogether it is a remarkably showy Orchid. It cropped up out of an importation and was first exhibited by Mr. Courtauld (an Orchid grower in Essex) at the great international show at Ghent. Orchid novelties just now are not as plentiful as they have been. The chief demand is for new Cypripediums and every nurseryman is searching for them. I lately saw a handsome new hybrid in Sanders' nursery named *C. Lemoinierii*, which may be best described as bearing resemblance to *C. caturum*, also a hybrid of the *Sedeni* type. But *C. Lemoinierii* is a much finer plant, more vigorous in growth, with larger flowers and more richly colored, the tints being of a bright reddish pink. This, too, was exhibited in Ghent, and was the admiration of the Continental Orchidists, who are also infected with the Cypripedium mania.

London, April 22d.

Wm. Goldring.

A Garden in Shanghai.

IN this place it is an easy task to transform a flat, dreary-looking piece of ground into a flourishing garden filled with a great variety of flowering shrubs. The country for miles around has been made by the silting up of the Yangtze River. About three hundred years ago the sea washed against the walled city of Quinsan, which is now thirty miles inland from here, rising from the plain like a miniature mountain, topped by its picturesque pagoda and left far away from any intercourse with foreign civilization. The alluvial plain for one hundred and fifty miles about Shanghai formed from the siltings from the Yangtze River gives strong nourishment to all shrubs and other plants; the dampness and great heat act as a forcing-house, and they grow as if by magic.

Before beginning to plant a garden the land must be raised several feet by making artificial ponds, the excavated earth serving as an excellent fertilizer, and around the ponds there is room for landscape gardening in miniature. At a short distance out in the country good grass sods (of a species of *Poa*) are found, and these, well laid in November, will give a beautiful lawn the following summer, if rolled and cut once a week, always leaving the cuttings, which serve the two-fold purpose of protecting the roots from the sun and of enriching the ground. Special care must be taken to keep out the Bamboo Grass and Clover, both of which grow rapidly and soon kill out the grass; but the expense of doing this is moderate, as small coolies are to be had for fifty or one hundred cash a day, the equivalent of five or ten cents.

The approach to our garden is through a pretty lane bordered on either side by *Ligustrum lucidum*, real Privet, which makes with its deep green leaves a good hedge, if constantly clipped, otherwise it grows into small trees from fifteen to eighteen feet high, which when in flower fill the air with a heavy, sickening odor. The entrance is through an archway made by two old Willows, whose lopped branches serve as a trellis-work about which a *Wistaria* winds itself with a python-like embrace, and every spring sheds a lilac-colored veil over these skeleton trees. Such is the profusion

of the flowers, that in time the weight of the creeper will break down the tree.

Near by are Locusts from seeds sent more than twenty years ago from the United States. They have flourished well. In spring the trees are bent with the graceful clusters of white flowers.

Stiff *Yuccas* growing in clusters from the same stem; fan-shaped Palms (*Chameroops humilis*); Bananas, not strong enough to bear the hard frosts without a straw covering; Cannas, which make themselves comfortably warm underground and spring up fresh every year—all these, with a background of *Pittosporum Tobira* and *Ilex cornuta* or Chinese Holly, with its horn-shaped leaves, give a variety of green coloring most restful to the eye during the blazing heat of summer.

The so-called Rose of Sharon (*Hypericum calycinum*) grows in profusion, covered with golden blossoms, and close at hand are several varieties of Gardenia, loading the air with strong perfume from their pure white flowers. English Ivy, Japanese Honeysuckle, Clematis (commonly called Passion-flower), *Bignonia Sinensis*, and several Roses, among them the Banksia, introduced into England from China many years ago, the Gloire de Dijon and Yellow Tea, are among the hardy creepers, but the lovely Moon-plant, a kind of exaggerated *Convolvulus*, with its perfect white disk-shaped flowers, droops at the earliest frost. Its seeds must be sown in March, and the seedlings kept under glass until June, for it belongs to the tropics. On first flowering, the long, spiral buds unfold as the sun goes down, closing before sun-rise and ending their ephemeral existence; later on, as the days become shorter and cooler, the flowers keep open during the morning.

Skirting the lawn are fine Fir trees, and the Cypress, always graceful, whether in the russet coloring of winter or when the soft spring air is calling forth its young, light green tips. The Tallow tree (*Stillingia sebifera*) colors its heart-shaped leaves with bright tints in autumn, and these, with the golden tones of the *Salisburia adiantifolia*, or Ginkgo tree, give a slight suggestion of New England October scenery. However, this home-dream vanishes as the eye falls on a cluster of feathery Bamboos, on the Fragrant Olive the Kwei-hua of the Chinese, and on the *Eriobotrya Japonica* or Loquat, with wool-covered flowers, made lovely only when the branches are bending with clusters of yellow fruit. These shrubs are over-topped by the *Melia Azedarach*, a good-sized tree, commonly called the Pride of India, which has fine heliotrope-colored blossoms in clusters. Below this is the *Magnolia grandiflora*. Much more stately and far prouder it looks with its glossy dark leaves and rich, large, creamy flowers.

On one side of the pond is a tangled copse filled with Privet (*Nandina domestica*), Rose of Sharon, *Pittosporum*, Palms and Bamboos, of which last there are sixty-three chief varieties in China. They are more valuable to her than her mines, and yield, next to rice and silk, the largest revenue.

There is no month in the year when some shrub may not be found in flower; for, although the range of the thermometer is great, reaching the high nineties in July and August, and falling to twenty-two and lower, often giving twelve degrees of frost, Fahrenheit, for several days at a time, still the cold is soon tempered by the force of the sun, which has been known to produce sunstroke in February; a rare occurrence, however. During the early winter months, large feathery branches of the Heavenly Bamboo, with brilliant bunches of scarlet berries drooping from the slender stems, are hawked about the streets. These are followed by Cherry and Almond blossoms. The Edgeworthia or Yellow Daphne decks its stiff, bare, brown stalks with soft yellow flowers before the frost has gone, and as the spring comes forward the *Magnolias* burst into bloom.

Photina serrulata, with its young red leaf-buds unfolding from amid the old, dark, evergreen leaves, gives the effect, at a distance, of a flowering shrub. *Daphne odora*, brought here from the hills at Ningpo many miles to the south, flourishes well, but must be protected from the scorching summer sun, as well as from the strong north-west winds. This is easily done by planting it on a bank which faces east and amid taller shrubs and trees. The flowers of the Peach, of the great Magnolia, of Althœa, and of the Albizzia, with fluffy pink blossoms, follow in quick succession; and before these have faded Gardenias and the Fragrant Olive are in bloom. After which winter is approaching, and again the *Nandina domestica* is to be seen.

Tulips, Hyacinths, Sweet Peas, Mignonette, Pansies, Salvias, Hollyhocks, Sunflowers, Zinnias, Canterbury Bells, Nasturtiums, Phlox—in fact, all garden flowers from the United States and Europe—have been introduced; many, however, must be treated in rather a reverse method from that usually employed on the other side of the planet.

Tulip and Hyacinth bulbs should be planted in October, and not left in the ground later than June, otherwise the rain and heat will rot them. Sweet Peas thrive best in large tubs, the seeds sown in September for spring flowering. The seeds of Canterbury Bells sown in the spring make a few leaves during the first summer; afterwards they may be transplanted in the autumn, and the following spring they are in perfection.

Mignonette does better in pots, although it will flower for a short time in the open before the damp heat comes.

The glaring red *Salvia* is well suited to endure the summer heat. This, planted out in the spring, comes to its greatest beauty in October, notwithstanding it had been in flower throughout the summer.

Each year new flowers are to be found in the different gardens; but the great question is, what will best stand the mid-summer heat on this alluvial plain?

My experience shows that different varieties of Japanese Lilies are more satisfactory, and are grown with less trouble than other flowers during the damp heat of June, July, August and September, giving a succession of flowers during these months.

Shanghai, February, 1888.

New or Little Known Plants.

Heliconia Choconiana.*

IN discussing a proposed trip to Guatemala in the spring of 1885 I was told of wild Bananas and wild Pineapples as growing in the forests of that region, and I was curious to learn what they might in reality be. The true Pineapple is indeed found there growing by the roadsides and in fence-corners, where the discarded crowns of devoured pines have taken root, and do their poor best to bear fruit again. But the so-called wild Pineapple I found to be the *Bromelia Pinguin*, which is planted for hedges and bears an edible berry. The "Bananas" were all species of *Heliconia*, of which I saw a considerable number growing on river banks, and in other damp places. Some were chiefly notable for their conspicuous inflorescence, formed of large brightly-colored bracts in close double ranks and enclosing the clustered flowers. Others were taller, with very large leaves and a decidedly Banana-like habit, but their resemblance to the Banana goes no farther and the fruit is never eatable.

Several of these were common on the banks of the Chocon River, but that which pleased me most was one with numerous smaller, bright green, and glossy leaves, which I discovered in a deluge of rain, and of which I afterwards secured the roots. This has recently bloomed in Cambridge, and appears to be a previously unknown species. The top of a stem and a single leaf of the natural size are here figured. (See page 162.) The clustered stems grow to a height of three or four feet, and are covered with the sheathing petioles of the apparently sessile leaves. The inflorescence is nearly sessile at the summit, declined, and consists of about half a dozen large, scarlet bracts, each enclosing a fascicle of long, pale yellow flowers. The segments of the triangular perianth are mostly coherent, only one of the sepals separating sufficiently to set free the anthers and the style. The fruit is about the size of a pea, roundish and truncate, three-celled and three-seeded, but indehiscent.

Cultural Department.

A List of Roses.

FOR those who care to cultivate but a few Roses and are not familiar with the many varieties now offered, the list below is given as embracing the best of the several types in commerce to-day. Of course there are many more varieties of almost equal merit which could be added to this list, but the difference between many of them is so slight that only an ex-

* *HELICONIA CHOCONIANA*, Watson, Proc. Am. Acad., xxiii. 284. Glabrous throughout, the stems sheathed with numerous leaves; blades of the leaves sessile on the sheaths, narrowly oblong-lanceolate, six to ten inches long by two wide, acuminate, shining; inflorescence deflexed, shortly pedunculate; spathes scarlet, lanceolate, two inches long, the lower empty and leafy tipped; flowers yellowish, equalling the spathes, the lower sepal free, the lateral connate with the petals; sterile stamen short, ovate, abruptly acuminate.

pert could distinguish them when blooming together. Those enumerated below are all distinct representative Roses. All are fragrant and all are more or less continuous bloomers, for while among those classified here as hardy the Hybrid Perpetuals are not strictly speaking continuous bloomers, yet with liberal treatment, as described in the last issue, they will reward the owner with some fine flowers at intervals all summer. Those described as tender—including types of Tea, China and Bourbon Roses—will, if carefully attended to, give flowers the whole summer from June till late October in the latitude of New York, and in all sections south of that line. In more northern parts of the country the season is somewhat shorter.

Do not be induced to try small plants if you want them to bloom in the open air the first season. For this purpose only good fair-sized plants can be depended upon. Many lovers of Roses have been discouraged because this precaution was neglected. It is a waste of money to buy cheap, small plants. By the time such plants have fairly started to grow October, and frosty weather overtake them, and a very few flowers of poor quality is the only reward for a summer's work and waiting. Procure strong plants and on their own roots if possible. Budded plants often throw up suckers from below, and the inexperienced are in many cases not able to detect the difference between the two until the finer kind is weakened and ruined by the more robust growth from the stock.

The following are hardy:

WHITE.—Coquette des Blanches, Columbia (new).

PALE SHADED PINK.—La France, Madlle. Eugène Verdier, Queen of Queens.

CLEAR PINK.—Madame Gabriel Luizet, Mrs. John Laing.

ROSE COLOR.—Anna de Diesbach, John Hopper.

BRIGHT RED.—General Jacqueminot, Ulrich Brünner.

DEEP VELVETY RED.—La Roserie, Jean Liabaud.

Of tender varieties, the following stand our trying summers remarkably well and give as much satisfaction as any I have tried.

WHITE OR FLESH COLOR.—Madame Joseph Schwartz, Marie Guillot, Malmaison.

YELLOW.—Coquette de Lyon, Etoile de Lyon.

PINK, OF VARIOUS SHADES.—Marquis de Vivens, Grace Darling, Edmund de Biazant, Duchess de Brabant (improved).

RED OF DIFFERENT SHADES.—Meteor, Queen of Bedders, Queen's Scarlet or Aggripina, Pierre Guillot.

Summit, N. J.

John N. May.

Polyanthuses.

THESE are variously colored florist's flowers that bloom in loose umbelled heads, and with flowers of all shades of white, yellow, rose, purple, maroon and crimson. While they can be grown successfully as hardy border-plants by protecting them with a light covering of evergreen branches or forest leaves in winter, it is only when treated in winter as cold-frame plants that they can be reasonably expected to flower in profusion and perfection from March till the end of May. They are useful as cut flowers in the same way as Pansies or Forget-me-nots, and they always appear more attractive when their own leaves are used as the green accompanying them.

They are true perennials, and in order to perpetuate special varieties we must treat them as perennials and increase them by division. A common way of treating them is to lift, divide and replant in some cool, moist spot out-of-doors as soon as they have done blooming, leaving them there till next fall, when they can again be lifted and replanted in cold-frames. But this is bad practice in one particular. I always have had the best success with Polyanthuses when divided in fall, and not in early summer.

Still, we now get such splendid varieties from seed, and so easily, except in the case of uncommonly choice sorts, that it is hardly worth while to bother with them as perennials, and it is better to treat them as annuals. Seeds sown now, or any time before August, should give capital plants for blooming next spring.

There are two distinct kinds of Polyanthuses—namely, the gold-laced, and the large-flowered, showy varieties. The gold-laced are beautiful flowers, with dark, velvety brown, maroon or crimson blossoms, whose petals are richly bordered with a distinct golden edging. The large-flowered varieties are the most robust, profuse, showy and useful, and include all the shades of white, yellow, rose-purple and crimson found in the race, and from a packet of choicest mixed seed we may get some of each sort. But as mixed seed does not give the best quality of flowers, it is better to buy the colors separately, say

a packet of white, one of yellow, one of dark crimson and one of spotted. This gives us a fine assortment, and among hundreds of plants, especially of the dark-colored ones, barely two are alike. Never buy inferior seeds, no matter how cheap they may be. If your object is to have fine flowers pay a good price for seed, and get the very best obtainable. The care in sowing, growing, wintering and blooming poor Polyanthuses

lath shading. But it is better to delay planting into frames until August, as the crowns are apt to grow too large to admit of blooming them at the regular distance—nine inches apart. And it is only as a matter of practical convenience that they are sown in spring; it is better to sow in June, and from the time the seedlings come up till winter sets in to keep them in active growth. They make just as good blooming plants for

Fig. 31.—*Heliconia Choconiana*.

is just as great as that required with the very choicest strain.

Sow Polyanthuses in boxes in a warm green-house in March or April; when they are up nicely prick them off into other flats, and about the end of April remove these to a cold-frame. After spring planting is over, say early in June, replant them into other boxes, and summer these in a cool, somewhat shady place, or transplant at once into a cold-frame, and shade with

next spring as do earlier sown seed, and they escape red spider, the inveterate enemy of old plants in summer.

Polyanthuses love a rich, friable, loamy soil, with a free supply of rotted cow manure, and during their whole life they should be liberally watered. During the winter months protect them in the frames with sashes and a little straw shaken over the glass. It is better to have the ground frozen about an inch

deep before covering at all, then aim to keep it frozen till February or March. So long as the ground is frozen we need not uncover or ventilate in winter.

Apart from blooming them in frames, we can use them effectively in out-door gardens. As soon as the frost is out of the ground lift the plants from the frames and plant them out in beds, borders or elsewhere in the garden in the same way as Crown Anemones, Forget-me-nots, Daisies and Pansies, and they grow and bloom beautifully. In this way they are extensively used in the Boston gardens.

William Falconer.

Viola cucullata.—We all admire the common blue Violets, so vigorous and abundant in bloom in moist meadows and rich woods in April and May, but it should be more generally known that they are excellent garden plants. They live and thrive in garden borders year after year, and that too in open sunny places, quite unlike the situations in which we usually find the wild plants. And like most other wild plants that enjoy a place in the garden, where they bloom more abundantly and form larger plants than in the meadow or wood. Besides the many shades of blue we find in this Violet, we have forms with pure white flowers and others variegated with white, and the two last are the favorites in gardens. In the woods and meadows hereabout, and between here and Oyster Bay, the variegated varieties are found in the greatest abundance, and the markings differ in almost every plant, indeed among these wild plants are more beautifully variegated forms than are ever seen in cultivation. Among the wild plants, too, are a great variety of cut-leaved forms, but these, for garden purposes, are less desirable than are the simple leaved ones. We have these Violets in full bloom now in our garden borders, and they are lovely companions of Siberian Columbine, Moss Pink, Virginia Lungwort, Golden Alyssum (*A. saxatile*), Siberian Corydalis (*C. nobilis*) and other beautiful seasonable flowers. If amateurs will now go into the meadows and dig up some clumps of these Violets, plant them in their gardens, and give them abundance of water for a month to come, they will soon be established and take care of themselves, and next spring repay this kindness with a profusion of blossoms. In digging up wild plants dig deep, and secure as many roots as possible; the mat of sod around the neck of the plants is only grass roots, the Violet roots go deeper than these. Never let them wilt between digging and planting.

W. F.

Tulipa Kaufmanniana is another of the fine Tulips discovered by Dr. Albert Regel in central Asia. It is a native of the mountains which rise above the valley of the river Tschirtschik and has lately been introduced into cultivation through the St. Petersburg Garden. It is allied to *T. Gesneriana*, and like that species is variable in the color of the flower, which ranges from different shades of red and yellow to white. In the form which Dr. Regel considers the type and has named *albo-variegata*, the segments of the flower are a bright rosy carmine on the outside, delicately streaked with white on their interior face, the claw brightly flushed with orange yellow within and less conspicuously marked with the same color on the outside, this marking on the outside of the outer series being reduced to a pale straw colored blotch. The leaves are oblong-lanceolate, five or six inches long by an inch broad, smooth and glaucous. The stem is about one foot high, and bears a single flower, an inch and a half to two inches long. It springs from a small ovoid bulb an inch in diameter, with brown membranous tunics slightly pubescent on the inside. *Tulipa Kaufmanniana*, var. *albo-variegata*, is a handsome and very hardy and desirable garden plant, flowering among the very earliest of the Tulips. It demands no special cultivation or care, and increases rapidly.

C.

Boston.

Cereus grandiflorus.—We have a large plant of this grand species growing in a rose-house, where it blooms lavishly every year, usually in May. In the event of bright warm weather the flowers open about sundown, but in the case of dull weather it is generally dark before they expand. According to the weather and the condition of the buds we can tell, a day or two ahead, the night when the flowers will open, and acting on this, can in the forenoon cut off the buds, which if left uncut would bloom that night, and send them to our friends. These buds will open and exhale their delicious fragrance nearly as well as they would if they had been left on the plant. The flower buds before they open have no fragrance; after opening, while they are somewhat fragrant all the time, their powerful odor is so intermittent—that is, it comes in puffs, as it were.

E.

Rose Princess Beatrice.—I consider this new Tea Rose among the most charming of all Roses, and finer blooms could not be grown in the height of summer than those now seen here. The form of the flower is exquisite, the petals broad and of thick substance, and recurved in the same pleasing way as in La France. The color of outer petals is pale primrose, which towards the centre deepens into a warm apricot. The scent is strong and the foliage broad, of a luxuriant deep green, which contrasts with the ruddy-tinged twigs and leaf stalks. It is evidently first-rate for forcing into early bloom. I call it new because it is not much grown yet, though Mr. Bennett, who raised it, obtained a first-class certificate for it from the R. H. S. in June, 1885.

Odontoglossum Harryanum.—There is quite a flutter among the orchidists about London in regard to this new Orchid since it has been rumored that some extraordinary varieties have been flowered, and others are likely to crop up. Mr. Harry Veitch has in flower a wonderful variety received from one of his correspondents. It measured nearly four inches from top of dorsal sepal to tip of labellum. The broad petals and sepals were of a peculiar shade of olive green and bronze, while the broad labellum was pure white, adorned with blotches and pencillings of a bright carmine. It is a long time since I saw an Orchid that captivated me by its beauty so much as this flower, and I know no other Orchid to compare with it.

W. G.

The Rock Garden in Spring.

THE handsomest flower in the Rock Garden this week is the Turkestan *Tulipa Greigi*, one of the most showy of all the Tulips. It is a dwarf species, bearing four glaucous-green leaves, of which the two lower are oblong-acute, five or six inches long by two and a half wide, the two upper narrowly lanceolate. They are conspicuously marked on the upper side with numerous oblong and linear bright chestnut-brown blotches, and are undulated on the margins. The stout, downy flower-stem is rarely more than two or three inches high. It bears a single campanulate flower, three to four inches deep, the segments spreading abruptly above the middle when fully expanded. The upper portion of the segments are bright crimson within, the lower third occupied by a large black blotch, surrounded by a distinct yellow border. This splendid plant, although apparently perfectly hardy, is a failure here in cultivation. Imported bulbs flower finely the first year after planting, but then gradually diminish and finally disappear. It is possible that they might give better results if they were lifted and replanted every year. Much more satisfactory, although a less showy plant, is *Tulipa Oculis-solis*, a native of Southern Europe, and for centuries known in gardens. It has three or four light glaucous leaves, a rather tall flower-stem and very handsome campanulate flowers, with acute, deep-scarlet-colored segments, two to three inches long, and, like those of *T. Greigi*, conspicuously marked on the inner side with a large black blotch surrounded with a yellow margin. This is one of the most beautiful of the perfectly hardy Tulips which can be grown here.

Several Fritillarias are now in flower. The Guinea-hen flower (*F. Melcagris*), a widely distributed European plant from Great Britain and Norway to the Caucasus, with large, pendulous, bell-shaped solitary flowers, checkered with dark purple, and borne on slender leafy stems a foot high, is an excellent and very hardy plant here, although now too rarely seen except in very old-fashioned gardens. It is a useful plant, too, for naturalizing along wood-walks and in other wild parts of the garden. There is a variety with dull-white flowers.

A handsome and very distinct hardy species is *Fritillaria pallidiflora*, introduced a few years ago from southern Siberia. It has large pale yellow, nodding, campanulate flowers conspicuously marked on the inside of the segments with small purple spots, and numerous glaucous-blue, lanceolate leaves. It is a vigorous and valuable plant, eight to ten inches high, and is now blooming in the same spot where it has stood undisturbed during the last five or six years. Every one who has ever been in a garden knows the stately old Crown Imperial (*Fritillaria imperialis*), with its whorl of red-brown, drooping flowers at the top of the tall leafy stems. It is a native of Persia, and has been cultivated in gardens during nearly three centuries. There is a variety (var. *lutea*), however, with clear yellow flowers which is rarely seen, in this country at least, although far more beautiful than the old-fashioned variety. It deserves more attention than it has received here.

The Summer Snowflake (*Leucoium astivum*) is in bloom. It is a very hardy bulbous plant, a native of central and

A New Jersey Pine Forest.—See Page 166.

southern Europe, and one of the handsomest and most satisfactory plants of its class in the rockery. It has dark green, linear, obtuse leaves, one to two feet long, and tall slender scapes, bearing at the summit a cluster of four to eight pure white, nodding, bell-shaped flowers, nearly one inch long, the tips of the segments marked on both sides with a green blotch. The Summer Snowflake will thrive in ordinary garden soil. The deep blue and the white flowered varieties of the Grape Hyacinth (*Muscari botryoides*) are in bloom. They are hardy little bulbous plants, from central Europe, with very short, dense racemes of small, nodding, bell-shaped flowers, and

linear, erect, glaucous leaves. They are well suited for the wilder parts of the rockery, and for naturalizing along the margins of woods and wood-walks.

Several native plants now in bloom are worth mention as interesting inhabitants of the rock-garden. The Moss Pink (*Phlox subulata*), a conspicuous feature in early spring on rocky hills in some parts of New Jersey, is common and well known in gardens; but *Phlox reptans* is seen more rarely. It is a dwarf species, with long and prostrate, creeping, runner-like stems, sending up low flower-stems, six to eight inches high, bearing a few-flowered cyme of handsome reddish

purple, long-tubed flowers, nearly an inch across. It is a native of damp woods along the Alleghany Mountains from Pennsylvania to Kentucky and Georgia. It is a hardy and desirable plant in cultivation, flourishing alike in shade and in full exposure to the sun, forming a dense, carpet-like mat. It is a good plant to use in covering the ground among shrubs in the rock garden, and is very easily increased by division.

The Twin-leaf (*Jeffersonia diphylla*) is a perennial, glabrous herb of the Barberry family. It sends up in early spring long, petioled leaves, divided into two half-ovate leaflets and naked one-flowered scapes. The handsome flowers are white, about an inch across, and are composed of four deciduous sepals, eight oblong, flat sepals, eight stamens, a two-lobed stigma, and an ovoid, pointed ovary. The pear-shaped pod opens horizontally near the middle, the upper part making a sort of lid. The Twin-leaf is an inhabitant of rich woods from western New York to Wisconsin and southward. It is attractive in foliage as well as in flower, and will flourish in any garden border. It is easily increased from seed, and by the division of the matted, fibrous roots. The genus *Jeffersonia*, of which a second species occurs in Manchuria, was named by Dr. Barton in honor of Thomas Jefferson.

The Mitre-wort (*Mitella diphylla*) is a common inhabitant of northern and western woods, where it is found in upland situations in deep rich soil. A mass of this graceful little plant is a pretty object in the shadiest part of the rock garden, where it throws up its tall, slender racemes of small, white flowers, before the leaves on the over-hanging trees appear. It has hairy, acute, heart-shaped, lobed and toothed, pale yellow-green leaves. The slender scape bears near the middle a single pair of small, opposite, sessile, acute leaves—a character from which the specific name of this species is derived. The Purple Trillium is a less showy and less attractive plant than *Trillium grandiflorum*, referred to in the last issue, but it is worth a place in the shaded rockery for the peculiar deep, dark, dull-purple color of the large flowers. It is a very common plant in rich woods, especially at the north.

The Canadian Violet (*Viola Canadensis*) deserves a place in every garden. It is a beautiful plant, with leafy stems, one or sometimes even two feet high and with white flowers tinged with violet. It is common in northern woods and on the Alleghany Mountains, and takes kindly to cultivation, springing up from self-sown seed in the shade and in the most sunny and exposed parts of the garden.

Boston, May 13th.

C.

Notes From the Arnold Arboretum.

Ribes saxatile is the earliest of the Currants in flower. It was the first shrub in the Arboretum to unfold its leaves. A native of Siberia and long known to botanists, it is not often found in gardens. *R. saxatile* is a very distinct, hardy, free-blooming shrub, two or three feet high, with erect branches covered with scaly reddish bark, and leaves, when the plant is in flower, of a delicate pale yellow-green color. The small yellow flowers are produced in short erect racemes. The fruit is small, spherical, bright red, acid and hardly edible.

Ribes alpinum, a red-fruited Currant common in the elevated deciduous forests of northern and central Europe, and of Russian Asia, where it sometimes forms a dense undergrowth, blooms here a few days later. It is a dwarf unarmed shrub, two to three feet high, with broadly ovate, serrate, lobed leaves and erect glandular-pubescent racemes of small flowers and large, handsome scarlet insipid fruit. This plant from a horticultural point of view possesses little interest except in the fact that it is one of the few hardy shrubs that will flourish under trees in a comparatively dense shade.

Two species of *Ribes* from our northern woods are also in flower—*R. rotundifolium*, with smooth or sometimes downy, round, heart-shaped, lobed leaves, slender peduncles, each bearing 1 to 3 small greenish flowers, and small unarmed fruit of agreeable flavor. The second species is the Fetid Currant (*R. prostratum*), with long, prostrate, unarmed stems trailing over the ground, deeply heart-shaped, lobed, doubly serrate leaves, and small greenish flowers borne in slender erect racemes. The pale red fruit is glandular bristly. The habit of this plant would give it a considerable garden value, in spite of the disagreeable odor it emits when bruised, were it not for the fact that when removed from its home in cold damp woods to more exposed and sunny situations, its leaves become disfigured by a fungus early in the season and often drop by mid-summer.

Ribes aureum, the Buffalo or Missouri Currant, of which several garden forms of no special interest are now cultivated,

is in flower. It is a tall, glabrous, unarmed and very hardy shrub, 6 to 8 feet high, common from western Missouri to Oregon, with three-lobed leaves and bright golden-yellow flowers in many-flowered racemes. The yellow fruit, which turns brown or nearly black when fully ripe, has a pleasant but rather insipid flavor. This is one of the hardiest and most easily grown of all shrubs; it will thrive in poor, sterile soil and under the shade of trees; situations where it is often difficult to make shrubs flourish. But the handsomest species of the collection and perhaps the handsomest of the genus is *Ribes sanguineum*, a native of Oregon and northern California, where it is common on the rocky banks of streams. Like nearly all the woody plants from that region it is not thoroughly hardy in New England, and must be carefully covered to protect the flowering wood. It is an unarmed shrub 4 to 8 feet high, with heart-shaped, five-lobed, serrate leaves and long drooping racemes of deep rose-colored flowers in the axils of large red bracts. The fruit is sub-globose, glandular, hirsute and unedible. Several varieties of some horticultural interest have originated in gardens, of which the most distinct are the var. *atrorubens*, with smooth, deeper colored flowers, and the var. *malvaceum* (*R. malvaceum*), with leaves hispid above, covered below with white tomentum.

Two Bush Honeysuckles (*Xylosteum*) of our North Atlantic Flora, *Lonicera ciliata* and *L. carulea*, are flowering. The former is a delicate and pretty shrub, which inhabits rocky woods from Massachusetts to Wisconsin and far northward. It sometimes attains a height of 5 feet, with erect or straggling branches, oblong-ovate leaves on slender petioles and rather large greenish-yellow flowers, produced in pairs on long single, axillary peduncles. The berries are red. *L. carulea* is a dwarfier plant rarely exceeding two feet in height; it is found in bogs from Rhode Island to Wisconsin and northward. It has oval leaves, pubescent when young, pale yellow flowers on short peduncles, their ovules later united into a single large, handsome, blue fruit. The two species take kindly to cultivation and are not particular about soil or exposure. They are interesting additions to any collection of shrubs.

Ostryopsis Davidiana is blooming in the Arboretum for the first time. It is the only representative of a genus of the *Cupuliferae*, closely allied to the Hazels; indeed some authors have included it in that genus, from which it is distinguished by its female inflorescence. This is a small ament, terminal upon the branches of the year, composed of ovate, leafy, two-flowered bracts, each flower enclosed in a leafy, coriaceous, lobed involucre, split on the ventral side, and in a tubular membranaceous exterior involucre toothed at the summit and analogous to the leafy covering of the hazel nut. The fruit, borne in clusters of six or eight at the extremities of the branches, is dry and indehiscent, and is enveloped in the persistent, striated, pubescent involucre. The nut is conical, obtuse at the summit, about half an inch long and crowned with the persistent stigmas. The male flowers, which are similar to those of the Hazel, are produced from the wood of the previous year. *O. Davidiana* is a graceful and perfectly hardy shrub, two or three feet high, with alternate, ovate-cordate, sub-acuminate leaves, pubescent on the under side. It is a native of Mongolia, where it was discovered by the Abbé David, and of the mountains in the neighborhood of Peking. It grows freely in any garden soil and requires no special cultivation or care. A beautiful figure (*t. 3*) was included by M. Lavallée in his "*Arboretum Segrezianum*."

Corylopsis pauciflora, now in bloom, is a native of Japan and a member of the Witch-hazel family. It is a dwarf deciduous shrub two or three feet high, with short pendulous racemes of yellow flowers, which appear before the leaves in the axils of large sheathing bracts, and which in structure resemble those of the Witch-hazel. This is a very compact, handsome plant of real ornamental value, which should be seen more often in gardens.

Two hardy Apricots are in bloom—a wild form of *Prunus Armeniaca*, the original of the cultivated Apricot, found by Dr. Bretschneider on the mountains near Peking, and common in northern China and Mongolia—a handsome erect shrub three or four feet high, of which there are two specimens in the Arboretum, one with pale pink, the other with nearly pure white flowers, which precede the rounded, sub-cordate, abruptly acuminate, serrate leaves, and small yellow or red, thin-fleshed, edible fruit. The second is the Siberian Apricot, which botanists now consider a geographical variety of the last. It is a taller plant, sometimes 20 feet in height, with a much lighter colored bark, and stouter branches, which are covered with pure white or pale pink flowers, preceding the ovate-acuminate leaves borne on glandular petals, and small,

scarcely edible fruit. It is a common Siberian tree, extending through northern China to Manchuria. It is very hardy here and exceedingly ornamental when in bloom. Another *Prunus* from the mountains near Pekin is now in flower in the Arboretum for the first time. Dr. Bretschneider considered this the wild single-flowered form of the well known flowering Almond (*Prunus [Amygdalopsis] triloba*), so common in gardens and one of the most beautiful of all early spring flowering shrubs. The Pekin plant produces in great profusion large pink solitary single flowers on its naked branches; and apart from its great botanical interest is a handsome and very hardy shrub, well worth cultivation. Its habit, its bark and foliage appear identical with the double-flowered plant.

Prunus Simonii, which Maximowicz, in his monograph of the species of the genus *Prunus* of Eastern Asia, considers the wild type of the Nectarine (*Prunus Persica nectarina*) is in flower. It is a dwarf tree, with erect branches covered, as well as the stem, with light gray warty bark. The leaves are oval, elliptical, denticulate and borne on short petioles; they are preceded by small white flowers, with oval, unguiculate petals and pubescent ovaries. The fruit has the grooved stone of a Peach and the smooth skin of a Plum. It is a handsome brick red, depressed-globular, and with a depression in the upper and lower sides. The flesh, which adheres to the stone, is yellow, rather juicy, although austere. It is not large, hardly exceeding an inch or an inch and a half in diameter, but doubtless might be greatly improved by cultivation. *Prunus Simonii* is a native of China, where, as well as in Japan, it is often found in gardens. Here it forms a small and perfectly hardy tree, with a strict pyramidal habit. Its resemblance to the cultivated Nectarine is interesting, and might be taken advantage of by pomologists to establish a new race of hardy Nectarines capable of supporting the extremes of our northern climate.

May 12th.

The Forest.

A New Jersey Pine Forest.

THE illustration upon page 164 represents a pure forest of Pitch Pine (*Pinus rigida*) in Ocean County, New Jersey. It is situated about twelve miles from the sea coast, and forms a part of the extensive and interesting domain which surrounds the Laurel House at Lakewood, to the proprietors of which establishment it belongs.

This forest is interesting from several points of view. It is extremely picturesque and beautiful. It occupies ground which only fifty years ago was employed for farming purposes; and it is one of few forests composed of a single species of tree which can be seen in the Northern States, where a number of different trees are usually associated together in forest growth. The Pines in this Lakewood forest have an average height of fifty feet; and their trunks an average diameter of ten inches. They stand so close together that grasses and undershrubs cannot survive in their dense unbroken shade. The forest floor is deeply carpeted with moss, however, and altogether this forest reminds one more of one of the planted Pine forests of northern Europe than anything we remember to have seen before in the United States. The rapid and vigorous growth of this young forest upon poor and comparatively worthless lands shows, moreover—and this is its chief interest—the way such lands along the Atlantic seaboard, north of Virginia, can be used to the best advantage. And finally it illustrates the possibility of protecting, by means of a little trouble and foresight, such forests from burning up in the fires which annually rage, unchecked, over great tracts in the New Jersey coast region.

The Pitch Pine springs up spontaneously on the sandy soil which adjoins the coast from Massachusetts Bay to the capes of Virginia. Land which has once been tilled and then abandoned again to nature, in all this region is soon covered with a dense and almost impenetrable mass of young Pitch Pines, which if fire is kept away from them soon grow into a valuable forest. If the young Pines do not appear spontaneously the seed can be sown, at a very trifling expense, and with entire assurance of an abundant crop. The seed of no other Pine, of no other tree, indeed,

sown in the open ground, germinates with such certainty, as the farmers in some of the towns on Cape Cod have shown; and there is no other tree which can be grown so cheaply on these barren, sandy soils, or give better results in so short a time. And could the people of New Jersey be induced to follow the example of the owners of the Lakewood forests, and protect and encourage the young Pines which are struggling to obtain possession of much of the lower part of the State, its wealth and prosperity might be very considerably augmented.

The Pitch Pine is not one of the most valuable Pine trees of the United States. Its wood is coarse grained, full of resin, and not very strong. It is in every way inferior to the wood of the southern Long-leaved Pine, which it resembles in structure and general appearance, but which it will never replace as long as the southern Pine forests continue to yield as freely as they do at present. But the time will come, perhaps, when New Jersey pitch pine will play an important rôle in supplying the people of the United States with timber. The southern pine cannot last forever, under the existing management of these forests, and the species which is everywhere replacing it, the Old Field or Loblolly Pine (*P. Tada*), is inferior to the northern Pitch Pine in the quality of the timber it produces. Before southern pine was brought to this market the pitch pine of New Jersey was the only available material in many parts of the State for timbers and flooring; and there are still houses in some counties where floors and floor-timbers are known to have been in constant use for more than a century. But it is for firewood and for charcoal that the pitch pine is most valuable; and the nearness and accessibility of these New Jersey Pine forests to great centres of population give them special importance as sources of fuel supply, which no other forests of this character in the country possess. Much land within three or four hours by rail of this city and of Philadelphia, now utterly unproductive and rapidly deteriorating through the fires which sweep over it every year, can be made highly productive and profitable by means of the Pitch Pine. People who own land of this character will see much to interest and instruct them in these Lakewood forests, and in those in the town of Orleans, on Cape Cod, in Massachusetts.

C. S. S.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—May I be allowed to say a word in defense of the Norway Spruce, which lately seems to have had the axe laid at its roots rather unmercifully?

It is quite easy to understand how it originally found foothold among us, because while young its habits and color appeared to be good, its native climate corresponded fairly well with our own, it could be imported at trifling cost, and was, for quite a long time, a well recognized favorite in landscape effect. To-day we see all over the older settled portions of the country a great many forlorn, weary looking trees that it would be a kindness to remove altogether. They are denounced as failures, and certainly we share the general opinion in asking for their extirpation. But we must emphatically resist the seemingly general verdict that the Norway Spruce is worthless for our planting purposes. On the contrary, there is not to-day one single evergreen that, under proper conditions, offers more inducements to the landscape gardener. Let me state these conditions briefly and you may judge for yourselves.

It is desired to establish a low evergreen hedge, of uniform color, dense habit, inexpensive and reasonably hardy. These are the essentials in a good hedge of this description, and for these good qualities, the Norway Spruce still compels your respectful attention. The Hemlock (*Tsuga Canadensis*) is handsomer, but it will not stand the hardships of our foreign friend. The Rocky Mountain Spruce (*Picea pungens*) is stiffer and probably more hardy, but not uniform in color. Even our White Spruce (*Picea alba*) is off color as compared with the Norway, though as a grown tree it is far superior.

Please bear in mind that our hedge is to be well planted in good soil, well trimmed each year, and never suffered in any way to deteriorate, so far as skillful maintenance can pre-

vent it. Under these conditions the Norway Spruce is ready to disarm criticism and challenge admiration.

Again, the Austrian and Scotch Pines are both excellent trees for a first establishment of wind-break in exposed situations, and any wholesale condemnation of them shows only a lack of knowledge as to their best possibilities. On the other hand, while the Douglas Fir appears in every way a most promising tree for our Eastern climate, it is proving a little too much on the part of "Strobus" when he calls attention to its remarkably handsome record in England. If this record proves anything it certainly goes to show that it is better adapted to the English climate than to ours, as we very rarely find the same tree doing equally well in England and New England.

In closing, let me state frankly that American trees are, for general use, far more valuable than foreign ones, but we should be very sorry to give up our acquaintance with many old favorites from across the water, especially as we are just beginning to find out exactly what their real value is likely to be to us here in the future.

Boston, Mass.

J. H. Bowditch.

[The Norway Spruce is unquestionably one of the very best Conifers which can be used in the Northern States to make a hedge. It grows rapidly, is very uniform in color, as our correspondent points out, and bears the shears well. The White Pine, too, makes an excellent and very hardy hedge; and with a little care in selection, plants of the White and of the Colorado Spruces could be found of uniform color. The last has probably never been tried as a hedge-plant. Its hardness, rigidity, pleasing color and pungent foliage seem to adapt it admirably for this purpose. It would not be surprising if the Douglas Fir should succeed equally well in England and in New England, although it is perfectly true that the same tree rarely does equally well in western Europe and eastern North America. Few trees flourish under such widely different climatic conditions as the Douglas Fir. It grows on the North-west Coast in a mild climate, where the annual rain-fall is between sixty and seventy inches, and on the dry eastern slopes of the Rocky Mountains of Colorado and New Mexico, where the cold is intense and the rain-fall is often less than twenty inches. The plants which grace the plantations of Great Britain are of Oregon and Californian origin. Those which now promise so well in our North Atlantic States are all from seed collected in Colorado.—Ed.]

Recent Publications.

Report upon the Forests of Honduras. By E. D. M. Hooper. London, 1887.

This is the last of a series of reports upon the forests of the British possessions in Tropical America, including those of Jamaica, of St. Vincent, of Grenada and Carriacou and of St. Lucia, made by Mr. Hooper, a trained officer of the Indian Forest Department detailed for this duty.

British Honduras owes its existence as a Colony to the value of its forests, and for two centuries the cutting and exportation first of logwood and then of mahogany has practically been the only occupation and the sole source of revenue of its people. The best logwood was used up years ago, and it no longer pays to export it; and the mahogany trade does not appear to be in a very flourishing condition. The large trees near the streams have been cut, and none remain except in remote and often almost inaccessible parts of the Colony. The government is now, however, fully roused to the importance of protecting the mahogany in the forests and has adopted stringent regulations controlling the cutting of these trees upon the public domain. Mr. Hooper recommends the organization of a forest establishment and the appointment of forest inspectors to regulate the cutting of Mahogany trees, the location of forest roads and the planting and care of valuable timber and rubber trees; and in view of the importance of the timber industry of the Colony his recommendations certainly should be adopted.

The forests of British Honduras, so far as their composition is concerned, can be grouped in two distinct divisions—the Pine forests of the coast and of the "Broken Ridges" of the

interior and the low-land hard-wood forests which cover the rest of the Colony. The tree which occupies almost exclusively the dry gravelly soil of the broken ridges is the *Pinus Cubensis*, a species which finds the northern limits of its distribution in South Carolina, and is common on our Gulf Coast east of the Mississippi. It is a very valuable timber tree; and it is not impossible that these Pine forests of Central America may become a considerable factor in the lumber supply of the world. The most important of them occupies "the Pine Ridge South of the Cayo stretching away south to an unknown distance and westward into Guatemala. Its area cannot even be guessed. And generally Pine forests may be said to occupy such land in the Colony as is raised above the general level of the country." Of the character of these Pine forests Mr. Hooper says: "Except in the narrow valleys, the forest of *Pinus Cubensis* may be considered a fine one. I counted 101 trees in a fairly average acre. The growth is tall and straight, but it is slow, a cut tree showing 60 rings in a radius of 6.6 inches at four feet from the ground, and at this point the bark was 1½ inches thick. A tree of 15 inches in diameter measured 75 feet in length to the branching and had a total length of 114 feet, while a tree 10 inches in diameter was 67 feet in length." The timber was found to be of excellent quality and hardly inferior to that of our Southern Pine, which it much resembles. The second division of the Honduras forests, that covering the general level of the country where the soil is deep and rich, is far more valuable and extensive. It consists of hard-wood trees. "This forest," says Mr. Hooper, "is difficult to describe." It is a majestic admixture of graceful trees of towering height with an undergrowth of all sizes—from small seedlings to large poles. The soil, which is of the richest loam, is carpeted with a thick growth of small palms, club-mosses and ferns, emerging from which is a small tree growth forming so thick an intermediate stage between the ground and the summits of the majestic trees that the latter can be recognized only from their bark displayed on a level with the beholder. Over the smaller trunks are festooned long garlands of Vanilla and other root Orchids, while parasites, with the most fragrant masses of flower, are clustered on every branch, interspersed with clumps of Bromelias and similar growths. The intermediate growth is composed in great measure of the Cohune palm (*Attalea*) and from its presence in quantity the type of forest takes its name. Its distribution is affected by the near presence of running water, for it often monopolizes the banks of rivers and is not so generally represented further away. It is found vegetating in clumps, small and large together—trees having as yet no stalk healthily growing associated with parent stems over which are masses of thick woody creepers, and were it not for the compactness of the growth giving material support, numbers of trees would be brought down by the weight of these climbers. The tree itself grows solidly even when in the open, it seems but little affected by wind and in this respect resembles Pine trees in being elastic. The tall tree growth which towers over the general forest includes Mahogany, hitherto the most important tree in Honduras, its export having been at all times the staple trade of the Colony. It is found in some less accessible parts in a state of natural distribution—that is to say, trees of all sizes and age in proximity to one another. Unfortunately this is seldom seen in the parts of the country which are within reach of the cutter. In other places where it has been, it is found no longer, the species being cut out and even seedlings are not present. Finally, in parts we see the young Mahogany, which is as yet in comparative infancy and has not pushed its head through the canopy of the older untouched trees; but should the demand for the undersized wood continue it is certain that, with the multiplicity of small mahogany merchants with little or no capital, this will also disappear and the Cohune forest within easy reach of streams will be without Mahogany. Apart from its appearance on Cohune ridge, I would add that the distribution of this species is general except on Pine ridge and the poorer broken ridges and Logwood swamps. Elsewhere it is common, whether in hills or in valleys, on rocky soils or deep loams." Mahogany is not the only valuable timber which these forests contain. Mr. Hooper in an appendix to his instructive report enumerates no less than 50 others of commercial importance, which when better known in Europe will greatly increase the revenue of the Colony. The fact that only 15 of these have been determined botanically during all the years that Honduras has been occupied by Europeans, shows the difficulty which attends the study of trees in the high, dense forests of Tropical America, and the field for investigation these forests offer to the ambitious and energetic botanical explorer.

Periodical Literature.

Writing of the "Spring Flowers of California" in the April number of the *Overland Monthly*, Mr. Charles Howard Shinn excites the envy of Eastern readers. February in California, he says, corresponds to the "changeful, sweet and coquetish" April of the English poets, and April in California means "the first radiance of the full Rose garden, the farewell of the scarlet Quince and the purple Lilacs." And among the wild flowers it means a profusion of blossoms, many of them identical in name with our own early summer species, but different in form and often much more brilliant, which contrasts very strongly with the humble efforts that the Eastern States make in this month to adorn themselves. No one, writes Mr. Shinn, who sees California for the first time now, can imagine how much more beautiful it was in the days of the pioneers, before "herds of cattle and bands of sheep trampled the soil and destroyed Nature's great wild garden," now "seas of flowers" have been exterminated, "leagues of wild Oats, Mustard fields in which, when in bloom, men on horseback could lose themselves, wild Lilies bedded in mass extending for rods. . . . Wild flowers that forty years ago spread in broad carpets from mountain to mountain across great valleys have retreated to bits of rock and ravine, to sunny hill-pastures and warm Oak-openings not yet needed for vineyard and orchard." Yet, we repeat, his account of what still remains suggests delights which may well make us envious.

Recent Plant Portraits.

ODONTOGLOSSUM URO-SKINNERI, *Le Moniteur d'Horticulture*, February.

EUCALYPTUS UINIGERA, *Gardener's Chronicle*, April 14th; from a tree grown in Scotland and now more than sixty feet in height. This is believed to be the hardiest of the genus. It is a native of the Tasmanian Mountains; and "may become," says Baron Von Mueller, "of sanitary importance to colder countries in malarial regions, the foliage being much imbued with antiseptic oil." This species attains a height of 150 feet, with a trunk circumference of eighteen.

ANTHURIUM CHAMBERLAINI, *Gardener's Chronicle*, April 14th; "one of the noblest species in a genus already rich in superb species, and handsome alike in foliage and in flower." It is supposed to be a native of Venezuela; and it has immense cordate leaves, three feet long and two feet wide, and "thick boat-shaped spathes about eight to nine inches long and four wide . . . of a pale, dull puce color externally, shining and rich deep crimson colored internally, bordered by a very narrow line of ivory-white, edged in turn by a narrow margin of yellow." The red-purple spadix is raised on an ivory-white stalk.

PEAR, BELLE PICARDE, *Revue Horticole*, April 1st.

MACARANGA PORTEANA, *Revue Horticole*, April 16th. A striking looking Euphorbiaceous tree, with bold, very large, ornamental foliage, introduced into the *Museum d'Histoire Naturelle*, from the Philippine Islands by the French botanical traveler, Marius Porte, to whom gardens are indebted also for *Phalenopsis Schilleriana*, *Phalenopsis Luddemanniana*, *Cycas Ruminiana* and many other interesting plants.

PHŒNIX CANARIENSIS, *Revue Horticole*, April 16th. A hardy and very graceful Palm, now very generally cultivated in the gardens of southern Europe. It is one of the best house plants, and may be expected to thrive in any part of the United States where the Orange is hardy.

Notes.

The interest now felt in American horticulture, and in some of our large collections of plants, especially of Orchids, in England, is shown by the fact that the supplement of a recent issue of the *Gardener's Chronicle*, of London, is devoted to a view of Mr. W. S. Kimball's collection of flowering plants of *Cypripedium insigne*, which contained, when this picture was made, not less than two thousand blooms, and must have presented a marvelous spectacle.

The entire stock of the remarkable white Chrysanthemum, Mrs. Alpheus Hardy—widely known by the striking illustration in the first number of this journal—has been purchased by W. A. Manda, of Cambridge, Mass. The price paid was \$1,500, the largest amount ever given for a Chrysanthemum, at least in this country. The flower was exhibited for the first time at the Chrysanthemum Show in Boston last December.

Mr. Thomas H. Douglas, a son of Mr. Robert Douglas, of Illinois, has been appointed by the Board of Forestry of California, Head Forester of that State. Mr. Douglas has already established extensive nurseries and trial grounds at Chico, Santa Monica and Hesperia. A map of the State showing the extent and character of the timber in the different counties is being prepared, and active operations looking to the arrest and punishment of persons setting forest fires, or illegally cutting timber, have been inaugurated.

Retail Flower Markets.

NEW YORK, May 25th.

There is a fair supply of flowers, with few really choice Roses. There is small demand for elaborate designs, the orders for Decoration Day being mostly for plants for embellishing statues, and wreaths for graves. Branches of blossoming shrubs are mixed with Roses in the large baskets made up for farewell tokens sent to steamers. Anna de Diesbach Roses are the choicest of Hybrids this week, and after these, Baroness Rothschild. Selected flowers with long stems cost from \$7.50 to \$9 a dozen. The former price is charged for the average lot of Hybrids. American Beauty sells for \$6 a dozen. Puritan Roses that are perfect are scarce and cost \$4 and \$5 a dozen. General Jacqueminots continue poor, and those grown in-doors are still declining; they cost from \$2.50 to \$4 a dozen. Moss Roses bring \$4 a dozen. La France Roses are abundant, and generally of good quality; they cost \$3 a dozen. Brides and Catherine Mermets cost \$2 a dozen. Perles, Niphetos and Souvenir d'Un Ami cost from 75 cts. to \$1 a dozen; Bon Silene from 50 cts. to 75 cts. a dozen. A few lingering Tulips of late flowering kinds are to be had for \$1 a dozen. Lilies-of-the-Valley are 75 cts. a dozen; Callas, \$2.50 a dozen; Poet's Narcissus from 50 cts. to 75 cts. a dozen, and Gardenias, \$3 a dozen. Lilacs are very plentiful and inexpensive, a large bunch being sold for 5 cts., on the streets and in the city markets. A few Field Daisies appear from the south, bring 25 cts. a dozen. The yellow Paris Daisy costs 50 cts. a dozen; fine Mignonette brings 50 cts. a dozen; it is small but well tinted. A few Pæonies have appeared, which sell at fancy prices. Carnations are scarce, but handsome; they cost 25 and 50 cts. a dozen, the latter price being for Buttercup and Grace Wilder.

PHILADELPHIA, May 25th.

Cooler weather has again made flowers scarce, but it has also toned up the quality and the demand has been greater. These conditions have caused a trade which is brisk for the month of May. Many out-door flowers have passed their prime, and this has caused Roses to be more in demand, although no material change in prices has taken place since last quotations. Amongst wild flowers Buttercups and the native Violets are extensively used, especially for personal adornment, and Columbines are occasionally used for the same purpose. Tree Pæonies are being cut in limited quantities, and sell at \$3 per dozen. They are decidedly coarse, but are useful in heavy decorations, and in the florists' windows they make an attractive display. Lily-of-the-Valley is still good, being cut out-of-doors; the foliage is thick and leathery in texture, and a dark rich green in color; very little is sold for less than \$1 a dozen. The beautiful Moss Rose with pink flowers is offered in limited numbers at from 25 cts. to 50 cts. a spray. The wonder is why more of these exquisite flowers are not to be had, for they are eagerly bought at the prices named. The difference in price is due to the different number of buds on the sprays. Single Dahlias still hold firm at \$3 a dozen, and Gladiolus is steady at the same price. Smilax, Asparagus and Adiantum are plentiful and fine in quality.

BOSTON, May 25th.

Bright weather has brought flowers in abundance and of better quality. The improvement is especially noticeable in Roses. Fine Jacqueminots and Madame Gabriel Luizets are in market, and are worth \$4 a dozen. Mermet, La France, Bride and Perle all sell for about \$2 a dozen. There is a fair supply of Papa Gontier coming in, and selling readily at \$1.50 per dozen. Carnations are unchanged since last week. Violets have disappeared completely. Pansies are growing smaller. The only Lilies-of-the-Valley obtainable are grown out-of-doors. Narcissus will last but a few days longer, and Tulips are in their prime. White Stocks and *Spiraea Japonica* are worth \$1 a dozen spikes. They are abundant, but probably not equal to the demand for Decoration Day. As this occasion approaches it becomes more and more evident that, owing to the backward season and the scarcity of out-door flowers, there will be a short supply in general, and prices will advance considerably. Among the brightest blossoms in the florists' windows are the Scarlet Nasturtiums, now quite abundant. They are sold in small bunches at 50 cts. a bunch. Cape Jessamines from the South have been sent here in small quantities this spring, but they do not seem to meet with the same favor with which they are regarded in other parts of the country. Hydrangea plants are very handsome just now, and there is a large trade in them. There will be an unusually large number of fashionable weddings next month. Some of the leading florists have already many orders in advance, and the prospects of the cut flower trade for the immediate future are good.

The Rainfall on the Plains.

SEVERAL weeks ago, in discussing the question of water supply on the Great Plains, it was stated in these columns that no data could be found to justify the belief that any increase of rainfall had followed the movement of emigration towards the Rocky Mountains. On the contrary, the calculations made by Mr. Gannett seemed to establish the fact that there had been no such increase. This is opposed to the statement often made that the simple planting of scattered groves of trees in Kansas and Nebraska has materially changed the climate in this regard, so that with more abundant rain, crops can now be raised beyond what was the western limit of profitable agriculture several years ago. It was added that if there has been any modification in the agricultural condition of the Plains which enables farmers to reap paying harvests where it was once thought that crops could be produced only by the aid of irrigation, this change could be accounted for on other grounds than that of an increased supply of water in the form of rain. It should be remembered that crops are often raised with profit on lands where the rainfall during the entire year, even if it could all be utilized, is not sufficient to insure a maximum yield. And in temperate climates it rarely happens that the rain which falls during the growing period of a crop is sufficient for its support. The water stored in the ground during the remainder of the year must be drawn upon to supply the enormous amounts given off by evaporation from the surface and by transpiration from the leaves of the plants. In estimating the value of any land for agricultural purposes, it is therefore necessary to take into account its capacity for absorbing and holding moisture as well as the amount of rain-water which annually falls upon it. And it is not improbable that the breaking up of the surface of the Plains has enabled the soil to receive and retain a considerable amount of the rainfall which would have flowed off into the streams from the hard, smooth face of the unplowed land.

These problems cannot be accurately solved until trustworthy data have been collected by years of patient investigation. Nevertheless the prevalent belief of intelligent men in these western regions is of great value as an indication of the truth. If it were their united opinion that the rainfall had increased, it would justify the supposition that there was some climatic change in this direction, although the extent and amount of such change would remain a most uncertain quantity.

This view of the case gives special interest to a chapter in the last quarterly report of the Kansas State Board of Agriculture which has just been received. Among the papers read at the annual meeting of the Board was one by the Secretary, in which the "improved condition of the water-supply in the State" was mentioned as one of the promising indications of a prosperous future for its agriculture. These improved conditions, the Secretary said, did not come from an increased rainfall, but probably from the loosening by tillage of the almost impervious crust of the prairie, and the consequent detention of the water which had formerly flowed off swiftly into the streams. A general discussion followed the reading of this paper, in which men from all portions of the State took part, and so far as the report shows, no one claimed that there had been the slightest increase in the rainfall. One member of the Board expressed the belief that "the State had been seriously injured by spreading abroad the impression that a wonderful climatic change was going on whereby the dry prairies were to be made to blossom as the Rose," and many others declared that long and careful observation had convinced them that no more rain fell now than when the prairies were trampled by immense herds of buffaloes. The opinion, however, was very general that the condition of the soil, as regards moisture, had been improved by cultivation, that there was more dew, that springs had appeared in places where none existed in earlier days, and that after heavy rains the streams did not rise as rapidly, nor to as great a height as formerly.

It was suggested in the discussion that Kansas farmers had learned to overcome, in a measure, adverse climatic conditions, by deeper and more thorough tillage and better cultivation. This may help to account for paying crops beyond the ninety-eighth meridian, and may modify the opinion that successful agriculture there is due alone to the increased storage of water in the soil. However that may be, the alert farmers of the frontier are wise in basing their hopes of success on something more substantial than the opinion that trees will call down more abundant rains upon their fields. That forests exert an important influence in conserving the moisture in the soil is an established fact, and the planting of trees where they will grow in the west, may, in time, render important service to agriculture. But the coming of this time will not be hastened by claiming advantages from forest planting which cannot be justified by any recorded experience or by scientific argument.

Formal Flower Beds.

NO question affecting the art of gardening is more frequently discussed than the question whether the formal flower bed is a thing to praise or to condemn, a thing which gratifies a cultivated taste or one which merely panders to the taste that delights in vivid chromos and in pinchbeck personal adornments.

About a hundred and thirty years ago the formal, "architectural style" of gardening—which had ruled in Europe for many centuries, and had found its most conspicuous expression at Versailles—was superseded by the "natural style," the style for which the distinctive name of landscape gardening was soon invented. Then for a long time the use of formal flower beds was almost as entirely abandoned as the use of clipped trees and straight-lined terraces. Even in small gardens given up entirely to the

cultivation of flowers (like the gardens of our grandmothers' days), although the paths might be straight and formally edged with Box, the plants themselves were not formally arranged—were not massed according to colors, nor clipped into uniform shapes, nor relieved against broad stretches of turf. It is only within comparatively recent years that there has been a return to the genuine pattern-bed, and its complement, the ribbon-border. An explanation of the revival of a taste for such beds and borders has often been found in that fancy for bright-flowered Geraniums which was so strong some twenty years ago that in England, at least, it amounted to a veritable horticultural craze, and in the general introduction a little later of the Coleus and other colored-leaved plants. But it is a mistake to attribute to a love for such plants the revival of a love for pattern-beds and borders. The converse statement would be nearer the truth; it might better be said that they became popular because public taste demanded just such plants for a particular purpose.

This purpose, if its results be carefully examined, proves to have been identical with the desire to increase the beauty of home-grounds in such a way that the smallest expenditure of thought and pains might produce the quickest and most conspicuous results. An immediate effect and a showy effect—these were the things desired in our gardens; and it was perceived that the most seductive recipe for securing them was to mass such plants as Coleus and Geraniums in large bodies so that their vividness of leaf and flower should be brought into strong relief by an expanse of closely cut turf. This desire was not in itself a very laudable one; and it would be easy to show that the recipe upon which it seized was not so satisfactory, even apart from æsthetic questions, as it appeared to superficial eyes. It would be easy to show that the practice of "bedding out" is, in the long run, the costliest which can be adopted for the adornment of a garden, whether large or small. But we are concerned just now simply with the artistic value of the formal pattern-bed. Is it a beautiful thing, or is it an ugly thing?

As thus put—in a general, abstract way—the question cannot be categorically answered. What must be said is that, like almost everything else in the world, a formal flower bed is beautiful or ugly according to whether it is in the right place or in the wrong place. It is never an isolated object. It is always an object which the eye embraces in a single glance with many others. And according as it agrees or disagrees with its surroundings, according as it helps or hurts the general impression which all together make, it is beautiful or ugly.

Let us see now what its characteristics are, in order that we may understand where it may be used to good effect, and where it can be used only to bad effect. They are easily defined characteristics: Conspicuous formality—that is, symmetry and rigidity—of outline and surface, and conspicuous brilliancy of color. And they are characteristics which, when thus set forth in words, themselves explain their right employment. When rigid, symmetrical lines of other sorts enter into a scene, and when a large spot of vivid color does not strike too loud a note in the general effect, then the pattern-bed is in place. Under other conditions it is out of place.

Unfortunately this is to say that, as we most often see it used, it is decidedly out of place—decidedly injurious to the scene which it is supposed to ornament, and, therefore, ugly in itself. We most often see it used to ornament the lawn in a place which has been laid out according to a natural, unsymmetrical scheme. No position could be worse for a formally outlined flower bed than one in which all the surrounding lines—alike of gravel walk, of free-growing shrub and of untrimmed tree—are varied, unsymmetrical and natural in effect. And no position could be worse for a mass of brilliant colors than an isolated position in the centre of a stretch of shaven turf. It ruins that air of unity, repose and breadth which is the one end and aim when a lawn is

created, while the wide carpet of green throws its own colors into such undue relief that it looks like a crude and gaudy picture hung on a strongly tinted wall.

In short, there must be something in the vicinity of a formal flower bed to suggest what it suggests itself, if the effect is to be a pleasing one. In the immediate neighborhood of a work of architecture a pattern-bed may be the most beautiful because the most appropriate object which could be introduced; or, if intersecting walks or roads leave a formally outlined space of small extent between them, formal planting may there be the best. In small urban parks, again, if discreetly introduced, it is harmonious, both as agreeing with the symmetry of street architecture and as filling a space palpably too restricted to be properly utilized by a more natural arrangement of plants. It is impossible in a single article to discuss the subject thoroughly. But enough has been said for the moment if we have shown the true point of view from which it should be approached.

The rapid introduction into general cultivation in this country of the purple-leaved Plum, known in gardens as *Prunus Pissardi*, to which attention is called in the notes from the Arnold Arboretum printed on another page of this issue, well illustrates the existing fancy in this country for garden novelties, and especially for plants with abnormally colored foliage or habit of growth. It is less than ten years since this plant was sent to Europe from Persia, and yet the owners of a large proportion of the pretentious villas in the United States now point to it with pride as one of the chief treasures of their gardens. Glowing descriptions in nursery catalogues, and gorgeous chromos in the hands of tree agents, for which style of illustration, the deep purple leaves of this plant are particularly adapted, have quickly spread it far and near. And this tree is neither very handsome nor very desirable, and it is certainly, as an ornamental plant, inferior in every way to the Myrobalan Plum, of which it is probably only a purple-leaved form. But no one ever plants the green tree, which is now practically unknown in this country, and which probably could not be found in any American nursery, while thousands of the purple-leaved variety are planted every year.

Terrace and Veranda—Back and Front.

THE following queries suggested by the "Plan for a Small Suburban Homestead," in the issue of GARDEN AND FOREST for May 2d, have been referred to me.

"On the south side, where, in a typical American house, there would be a shady veranda, instead of it there is what is called a terrace—an uncovered platform—upon which the sun must fall and be reflected with burning heat and blinding light into the adjoining rooms. The house has no front door. To enter it from the street, visitors must go round by the back yard, close by the stable. What can be said for such arrangements except that they are striking from their originality or their foreign character? If a speaker chose to turn his back upon his audience he would offend a sense of propriety. Is there no question of propriety about the front and back of a house?"

I reply with pleasure to these inquiries.

A well-shaded apartment having been provided, outside the walls, at the south-west corner of the house, much better adapted for the seating of a family circle than an ordinary veranda, the platform called a terrace will serve desirable purposes that a veranda in the same situation would not. The family rooms giving upon it can be opened to sunshine, as it is best that all rooms should be occasionally, summer and winter. The sun can be excluded from them when it is better that it should be (leaving the air free course through the windows), by adjustable awnings. Interesting forms of decorative sub-tropical vegetation can be fittingly set upon such a terrace in immediate connection with the principal family rooms, as they could not be in the

shade of a veranda. There are several months in the year when the terrace could be occupied for one or two hours of most days as a work-room for ladies or as an airing place for an infant or a convalescent, when it would be imprudent to sit in the shade out-of-doors, or to walk on damp turf.

As to a common sense of propriety and respectability in matters of the front and back of houses, let us consider how what may pass for such a sense has probably originated.

A feudal chief wishing to lodge a body of his vassals at a particular point, before unsettled, of his domain, would provide rows of huts set closely together on each side of a common passage or street. They would have the characteristics of such huts as are to be seen now by the score, for example, at Paso del Norte on our southern frontier; a single room for a family, a door on the street side, a door on the other side, no windows, a little corral into which goats, swine and fowls are driven through the hut at night-fall.

As civilization advanced the manorial lords would find it to their profit to extend these villages, build larger dwellings, and, after a long interval, give them a little window on each side of the street door. Later, the roof would be pitched steeper and a sleeping-loft added. Then, on the street side, the walls would be built higher so that there could be upper rooms, also with windows, the roof still carried down to the first story on the opposite side.

At this stage of the evolution certain landlords might come to regard certain of their villages as a part of their lordly array; to conduct guests through their streets and to take pride in their cottages as they would be seen from the streets. It follows that new cottages would be built a little set off from the street and would be given a street doorway; their street walls would be whitewashed and tenants would be encouraged to decorate the street yards with flowering plants and to line the ways from the street to the street doors with rows of box or shells or white stones. The other side of the house would still preserve the original hovel character; would have no windows, and the door would open upon a dunghill and rough shelters for the increasing personal wealth of the tenant in goats, pigs, donkeys, geese and fowls.

It can hardly be necessary to pursue the process of development nearer to "the typical American house."

Why is it that we so often see the family rooms of a house in the country on the least valuable part of the site of a homestead; the kitchen, wash room, drying yard and out-houses on the best part of it? Why is it that if one asks at a Seaside Hotel, where he can see the ocean, he is told to go out back of the stable? The answer is that it is because of a lingering superstition—a spurious semi-religious sentiment—which had its origin when one side of most houses—the side facing a public road—was the human side, the other the side of pigs and goats and geese, filth, darkness and concealment.

The front, the back, are terms no more applicable to a well designed house in America than anywhere else. Our Capitol and our White House have two fronts. Our beloved house at Mt. Vernon has two fronts. The old Hosack house at Hyde Park on the Hudson, the finest country-seat in its natural elements in America, has four fronts, as have most palaces and many other monumental buildings, as those of our Interior and Post Office Departments. (But this is a plan hardly ever to be recommended except where there is to be a spacious interior court, as in many French and Spanish country houses.)

Generally with us a country house, and often a suburban house, will best have three fronts. Except as regard for winter shelter or summer breeze may overrule, one of these will be on the side looking from which there is the most pleasing natural scenery, and here will be the more important family rooms (as at Mt. Vernon and at the White House). If the outlook from them has a fine distant background (as at Mt. Vernon and the White House), then the

nearer premises should be treated partly with a purpose to provide a place of common, quiet, domestic occupation, to be used in connection with the parlor or library, and partly with the aim of fitting the landscape with a foreground nicely conforming to, and helping the effect of, the middle distance and the background. It is desirable for neither of these purposes that there should be a sweep of gravel on that side of the house upon which horses may be driven or be kept standing, nor that there should be a public entrance to the house there. Usually a lawn, framed and sparingly furnished with masses of shrubbery that will not grow so high as to hide the distant view, will be best. But if the natural surface of the ground is rapidly declining from the house, especially if it is in the form of a broken and one-sided declivity, having a dislocating effect in connection with the distant view, then a level platform before the house, its further edge having a parapet, balustrade or hedge, will be desirable, both in order to give an effect of security and quiet to the immediate border of the house, and to make a strong foreground line by which the distance will be softened and refined.

Another side of the house will be its garden front, chosen because (of the three remaining sides) it offers the best conditions for a garden, properly so called. Another will be the entrance front, the treatment of which will be large in scale and less fine than either of the others. But here, if possible, there should be umbrageous trees. There will remain that part of the house containing the kitchen and laundry, from which will extend yards and sheds and spaces where wagons can stand and turn when bringing supplies or taking off wastes. Beyond them, perhaps, a carriage-house, stable and smaller out-houses. This should be the side on which the outlook is of the least value, and on which the natural circumstances favor convenient but not conspicuous lines of approach.

When such a complete arrangement, as has been thus suggested, is impracticable, the same general principles may be adopted as far as circumstances admit. It rarely occurs in any interesting place that the principal entrance can be best made on the more attractive side of a house. It often occurs, as in the finest places at Newport and Long Branch, that the best location for the stables, stable yard and laundry yard is on the street side of the house, and that the approach to its principal entrance passes near these, bringing them, exteriorly, under close view.

Brookline, May 18th, 1888.

F. L. Olmsted

The Court-yard of Charlecote Hall.

AS has been said on a previous page, the beauty of a formal flower bed depends upon the question whether it is in the right place or in the wrong place. It may be more beautiful, because more appropriate, than any other horticultural decoration; and it may be more ugly because more conspicuously inappropriate than any other. Our own home-grounds, both large and small, offer numberless instances of its improper use. Examples of its proper use are not so easy to find in America; and even in Europe we more often deplore than welcome its presence. When the natural or landscape style of gardening came into favor, the reaction in taste carried artists and owners alike into an excess of hatred for all formal gardening arrangements. Many old gardens of the architectural pattern were ruthlessly destroyed, although they were appropriate and beautiful because closely connected with works of architectural art. And the formal beds of modern times are, as a rule, not much better employed in Europe than in America. But here and there in all parts of Europe, and even in England, where the love for natural arrangements long ruled more strongly than elsewhere, old gardens of architectural design, or portions of such gardens, may still be found. The illustration given on page 173 is a good example of gardening of this character, and gains a double interest from its connection with the name of the greatest of English poets.

Charlecote Hall stands some three miles from Stratford-on-Avon, and was in Shakespeare's time, as it still is to-day, the seat of the Lucy family; and it was in Charlecote Park that, as the familiar legend tells us, the young poet played the poacher's part. The hall, as it stands to-day, scarcely changed as regards its exterior, was built in the first year of Queen Elizabeth's reign—in 1558, six years before Shakespeare's birth. As we see it to-day, therefore, he must have seen it; and not only the Hall itself, but the gate-way and court-yard which our illustration shows, for these form an integral part of the plan of the building itself. Our point of view is from a spot immediately in front of the Hall, the projecting wings of which are joined by the terrace walls on either hand. Thus house and walls and gate-way completely encircle the court-yard, and the architectural design of the little garden it encloses was dictated by good taste. Imagine this small space arranged in the natural style of gardening, and we perceive at once that the planting itself would be ineffective, and that the effect of the architecture would be grievously impaired. Beyond the walls the naturally growing trees give an accent of variety, and pleasantly suggest the beauties of that wilder nature which the word park implies. But within the walls the formal beds are properly placed, and even if vivid in color they cannot be too emphatic in effect, for they are not set in immediate relief against a carpet of bright green, but are surrounded by borders of gravel the neutral tones of which, together with those of the architectural elements, must subdue the brightest floral notes into a general harmony.

Entomological.

The Work of a Timber Borer.

AS is well known, the borers of some of our shade trees, as well as the grub or larva of the *Monohammus* of the White Pine, occur in lumber, and, on very rare occasions, live on for many years, either as larvæ or beetles, probably the latter, in lumber which has been made into tables, chests of drawers or other articles of household furniture; the beetle for a long time afterwards giving out ghostly squeaks, finally emerging from its tunnel in the well-worn and familiar bureau or table, as the case may be. The latest occurrence recorded in print is noticed by Mr. J. McNeil, who states in the *American Naturalist* for December, 1886, that two specimens of a longicorn beetle (*Eburia quadrigeminata*) must have lived in an ash door-sill for a period which "would make these insects not less than nineteen, and probably twenty or more years old." A somewhat similar case happened at Salem, Mass., as we have been informed by A. C. Goodell, Esq., who took a "sawyer" beetle (*Monohammus confusor*) from a bureau that had been in his house for fifteen years, and was new when bought.

Apropos of such cases of extraordinary longevity in boring insects whose life ordinarily spans but two, possibly three, years, and which occur in articles of furniture, the Messrs. Goddard Brothers, of Providence, R. I., have called our attention to the damage done to a case of cotton cloth at their Lonsdale Mills, and have kindly presented the three larvæ found, together with a damaged bale of cotton cloth, to the Museum of Brown University.

The box containing the goods was of pine, and perforated by at least three or four grubs, seventeen pieces being worm-eaten, one of which we have examined. The worms were thoughtful enough to gnaw through the folds, so as to thoroughly riddle almost every thickness of the cloth; the perforations in one case being about three inches long and half an inch wide on the outside, and contracting for two inches within to a size corresponding to that of the body of the grub. Not having seen the box, I quote from a letter to the Messrs. Goddard from Mr. J. Johnston, of Lonsdale, who took some pains to examine the box and

to identify the worms as larvæ of a beetle. "The hole they make is in shape a very elongated oval, and is, I think, in every case about the size of the grub itself. It is unfortunate that we did not see the case as it was seen in Philadelphia. The bottom, where most havoc was wrought on the cloth, was mended with a strip of hard pine; possibly the original board was so badly damaged that it would not have been safe to return the goods in it as it was. On examining the shooks in the box-shop, I find a large proportion of them eaten by this embryo beetle. I ought to say that not a single grub can be found in the shooks; those I send were taken from live wood."

We are informed that this is the only case of the kind which has occurred out of about 250,000 boxes sent out from the mill. How long the larvæ may have lived in the lumber is, of course, difficult to say.

The larvæ, one of which was still alive, were about three-quarters of an inch in length, and on comparing them with the half-grown larvæ of *Monohammus confusor* of nearly the same size they were found to differ as follows: the clypeus and labrum are wider, the edge of the prothoracic segment is more hairy; the body is wider behind the thoracic segments, and more rounded and wider at the end. Without doubt these larvæ differ generically from *Monohammus*, but in the present state of our knowledge, it is impossible to refer them to their proper genus and species.

We may here remark that the larvæ of *Monohammus confusor* live two years before transforming into beetles, as we have been able to prove, having been fortunate enough to detect a female in the act of laying its eggs, and the year following to cut its half-grown grubs out of the same tree.

It is probable that the cases of extraordinary longevity on record are due to the fact that through some cause the insect as a beetle has been prevented from leaving the tunnel made while a grub. Its larval state may not be prolonged, but when insects are prevented from mating and laying their eggs, they live on in single blessedness through an unusual number of seasons. There is thus, apparently, a premium awarded by Nature upon celibacy, the reward being length of years. A. S. Packard.

New or Little Known Plants.

Camassia Cusickii.*

THE only American genus representative of the large Liliaceous tribe which includes the Hyacinth, the Blue Bell or Grape Hyacinth, the Squill, and the Star of Bethlehem, is the genus *Camassia*. So near to *Scilla* is this genus that it is often included under it, and we so find it in Gray's Manual. The characters which separate the two are the leafy stem, the stouter habit, and larger flowers, and the nervation of the petals, which in *Scilla* are always a single midnerve, while in *Camassia* there are from three to nine nerves, showing most plainly after the flowers are dried.

The first known species was discovered by Captains Lewis and Clark in September, 1805, upon their expedition across the continent. After a difficult passage across the Bitter Root Mountains, by what is now known as the Lolo trail, during which they had found little grass for their animals or game for their own sustenance, they came out on the tenth day upon an open meadow and to an Indian village, where they were hospitably received. The Indians "set before them a small piece of buffalo-meat, some dried salmon, berries, and several kinds of roots. Among these last is one which is round and much like an onion in appearance and sweet to the taste. It is

* C. CUSICKII, Watson, Proc. Am. Acad. xxii. 479. Bulbs clustered, large; leaves glaucous, subundulate, numerous, the larger two feet long by one and one-half inches wide; stem leafy, two or three feet high; pedicels 2-3 linear subscurious bracts about an inch long; flowers regular, pale blue, the narrow petals crisped near the base, 3-5 nerved, persistently spreading, an inch long; capsule oblong, transversely veined.

called quamash, and is eaten either in its natural state, or boiled into a kind of soup, or made into a cake which is then called pasheco. After our long abstinence this was a sumptuous treat." Seventy-five years afterward I crossed the same trail, still as wild, rugged and inhospitable as the earlier voyagers had found it, and came out into the same little prairie. The Indian village had vanished, but heaps of recently gathered Camass roots showed that the Indians still frequented the place, while marks of a mowing machine upon the grass were equally sure evidence of the near neighborhood of some white settler. Lewis and Clark in their narrative make frequent mention afterward of "quamash flats," and upon their return took back with them the specimens upon which Pursh founded the species *Platangiun Quamash*. This name Lindley subsequently changed to *Camassia esculenta*, the *Camassia* being a Latinized form of the Indian name *quamash* or *camass*.

nerves. It is described as growing on mountain slopes, instead of in meadows, and the bulb is nauseous, pungent and inedible. The figure on page 174 has been drawn by Mr. Faxon from a specimen that has recently flowered at Cambridge. S. W.

Plant Notes.

The Ginkgo Tree.

THE Ginkgo tree, as it is generally seen in this country, especially in the Northern States, where the climate is perhaps too severe for its full development, has rigid branches, and a stiff and not particularly attractive habit of growth, which make it difficult to use this tree satisfactorily in connection with other trees of less formal outline. As it approaches maturity, however, under favorable conditions, the Ginkgo, as our illustration on page 175,

The Court-yard of Charlecote Hall.—See page 171.

In 1810 Nuttall collected what he believed to be the same species "near the confluence of Huron River and Lake Erie," and afterward near St. Louis and on the banks of the Ohio. This eastern form, which ranges southward into Texas, was separated by Dr. Torrey and is known as *C. Fraseri*. The original Camass is abundant in many low meadows from Idaho to the Pacific, and has been an important article of food to the native inhabitants. On the lower Columbia, a third species, *C. Leichlinii*, is found, which has an equally nutritious root, and still a fourth species has been recently discovered in the Blue Mountains of Oregon, by Mr. W. C. Cusick, of which a figure is here given.

This is the stoutest and most vigorous grower of all the species, with a large bulb, numerous broad glaucous and somewhat undulate leaves, and a flowering stem two or three feet high. The flowers are of a delicate very pale blue, the petals spreading regularly, crinkled at the narrow base, and with three, or rarely five, faint

representing the noble specimen in the famous gardens of the Villa Carlotta, on the shores of the Lake of Como, shows, is a really beautiful and graceful tree, which will hardly be recognized by persons who have only seen it in a comparatively young state in parks and gardens in the Northern States. Most of the specimens in the United States still require time, probably, in which to develop their real beauty, but that they can in time attain the same graceful habit of growth, if not the same dimensions, as the tree we figure, the fine specimen planted in the first years of the century by Dr. Hosack, on the banks of the Hudson, at Hyde Park, amply testifies.

The Ginkgo, apart from its beauty, is a tree of very great interest, owing to the peculiarities of its botanical characters. It is one of the family of Conifers, but unlike the members of that family with which we are most familiar in this country, its leaves are deciduous, broad and fan-shaped, and instead of a cone, the fruit is a fleshy drupe, containing a large stone resembling that of an Apricot, and

with a delicate edible kernel, although the fleshy portion of the fruit has a most disagreeable rancid flavor. The male and female flowers are produced on separate trees, so that it is necessary to plant specimens of the two sexes in order to insure a crop of fruit, which is not produced until the trees have attained a considerable size. The Ginkgo is supposed to be a native of some part of northern China, where it is frequently cultivated in the neighborhood of temples and palaces, but it is nowhere known in a wild state. It has been cultivated in Japan, where it is believed to have been introduced, from time immemorial, and where it is valued for its beauty as well as for its nuts, which are highly esteemed by the Japanese.

This tree was introduced into Europe about 130 years ago, and it must be nearly a century since it was first sent to America. The peculiar shape of the leaves has gained for it the name of the Maidenhair tree, from their supposed resemblance to the fronds of the Maidenhair Fern. It is a large tree, producing valuable timber, sometimes attaining in Japan a height of nearly 100 feet, with a trunk three or four feet in diameter. The Ginkgo, to which the name *Salisburia* is sometimes improperly given, is very hardy as far north, at least, as New England, although a milder climate seems necessary to develop its greatest beauty. Considerable attention has lately been given to the Ginkgo in Europe, as a subject for street and road-side planting, and thousands of these trees have been planted during the last few years along the highways near some of the French and Italian towns of the Riviera. Its hardiness and its habit of growth seem to fit it admirably for this purpose.

Old Lombardy Poplar at the Trianon.—In the charming park of the Trianon where Louis XIV. was wont to retire for a time—when he was tired of the splendors of Versailles—stand the remains of a fine old Lombardy Poplar which was planted by Marie Antoinette. The top of the tree was blown off by a storm in 1880, but the trunk is yet full of life, and has a circumference of seventeen feet six inches, four feet from the ground.

Sugar Maple.—A diligent search through the park at the Trianon for trees, original specimens introduced into France by Michaux, was not successful. Since Michaux's time there have been revolutions and changes of Government, and the authorities do not seem able to point to many trees which can be said, with certainty, to date back to Michaux himself. One, however, a goodly sized Sugar Maple, is probably an original tree, and it was, by no means, in thoroughly good order, as the Mistletoe had taken complete possession of it. The branches were weighted down with this parasite, although the year before large quantities had been carefully cut out.

Ginkgo biloba.—A fine pair of these trees—perhaps better known under the name of *Salisburia adiantifolia*—stand in the State nurseries at Trianon. They are a male and female, and the latter was laden with fruits at the time of my visit last autumn. The larger of the two had a trunk which measured more than two and a half metres in circumference. It seems strange that so handsome a tree has not been planted more

generally along avenues in France. A gentleman now residing on the Riviera, familiar with the *Salisburia* as a street tree in Shanghai and other Chinese towns, has, at his own expense, planted avenues of it in some of the small Italian towns near the French frontier. If these succeed, and there seems no reason to doubt it, the Ginkgo will probably become popular throughout southern France.

Fig. 32.—*Camassia Cusickii*.—See page 172.

Actinidia volubilis.—Has any one grown this shrub in the United States for the sake of its fruits? A fine specimen, trained to a stake, at the Chateau de Segrez, was, last autumn, laden with round fruits, green in color and about the size of a large hazel nut. The taste was decidedly agreeable, the flavor not unlike that of some kinds of gooseberry. Probably the best and most complete collection of hardy ligneous plants,

not only in France, but on the Continent of Europe, exists at Segrez; it represents many years of care and study, and cannot fail to impress the visitor with the value of the labors of the late M. Alphonse Lavallée. It is earnestly to be hoped that the present representative of the family will follow up the work carried on with so much enthusiasm by his father.

George Nicholson.

In most green-houses such vines as Passion-Flowers, Stephanotis, Allamanda, Quisqualis, Lapageria and the like are trained to wires running along the rafters or lengthwise across the rafters. Unfasten these now and give them a thorough cleaning before tying them up again. To remove the coating of black dirt often found on the old leaves of vines, keep the leaves wet by sprinkling them with water for some hours

Fig. 33—The Ginkgo Tree.—See page 173.

Cultural Department.

The Green-house.

GREEN-HOUSES have now been emptied of summer garden plants, and many winter-blooming plants have been turned out-of-doors for the summer to complete their growth and ripen their wood. This gives an opportunity to clean thoroughly green-houses and the plants remaining in them, and to rearrange and display them to the best advantage.

Wash the dark stains off the sash-bars and rafters and scrub the dirt and green confervæ off the plates, sills, stages and walls inside. Glass partitions and doors are apt to become dingy, and they should be well cleaned. If the houses are old, and there is any appearance of mealy bug about the plants, paint the wood-work inside with turpentine or kerosene, and stop all nail-holes and cracks with putty or rubber cement.

before washing. This softens the scurf, and it can be washed off with comparative ease.

The in-door decoration of the green-house in summer depends upon the kinds of plants grown, the purpose for which they are required, and the room and other conveniences at hand. Green-houses in summer are not in all cases genial homes for plants; they are apt to become too hot, hence gardeners provide out-door summer quarters for all the pot plants which are benefited by such treatment. But if the summer decoration of the green-house is desired there are among fine-leaved plants Palms, Anthuriums, Caladiums, Dracænas, Crotons, Marantas, Begonias, Ferns, Mosses and many others. See that all are perfectly clean and in good condition at the root; that they are neither over-potted nor under-potted; that the drainage is perfect, and that they are so arranged that each plant has abundance of room, and that all are arranged effectively and tastefully. Among flowering plants there are Gloxinias,

Achimenes, Gesneras, Begonias, Anthuriums, Clerodendrons, Dipladenias, Crinums and Crassulas. To these can be added a host of Orchids. If it really is desirable to maintain a gay conservatory all summer long, it will be necessary to keep up a supply and succession of flowering plants in summer as we do in winter. Hydrangeas, Plumbago, Cockscombs, Brugmansia, Ceanothus, Justicias, Erythrina, Japan Lilies, Crape Myrtle and plants of their kind are used for this purpose, and they often are supplemented by the commoner annuals. But there is a peculiar cheapness about this sort of decoration. Plants that thrive better out-of-doors than in the green-house in summer assume a very unhappy aspect when in conservatory service during that period.

Hardiness of Perennials.

THE question:—What is the test of hardiness? recurs every spring. Too often we conclude that a plant is not hardy because it does not survive the winter, under certain conditions. But a wider experience proves that a plant's ability to endure winter cold depends as much upon summer heat as upon winter climate. The conditions of a plant under cultivation, differ widely from those of the same plant in its natural habitat. Observation seems to show that perennials are more common in woods, or shady places, and moist meadows; whereas annuals mostly grow in dry and exposed situations. May we not infer from this, that exhaustion during the hot season by excessive blooming and seed producing, as in the case of Aubrietias and Sweet Williams, tends to make annuals rather than perennials of them, and lessens their ability to endure winter cold? For this reason, we can never hope, perhaps, to practice spring bedding in this country with the success attained in England. Some of the most successful gardeners in America have pronounced it uncertain. I am referring more especially, though not exclusively, to plants suitable for the rock-garden. In forming a rock-garden an eastern or south-eastern slope is certainly preferable, but culture will, I think, be attended with greater success if some shade can be secured, such as is given by large trees at some distance away, so as not to have their roots penetrating the soil in which the plants are grown.

Apart from the question of reduced vitality, through excessive heat in exposed situations during summer, the ability to endure winter is not measured by counting the degrees on the thermometer. It depends upon other conditions than the mere amount of cold. Equable conditions are required. Any plan by which we can exclude sun-light and admit air, and so prevent alternate freezing and thawing, will help. I am surprised to find *Narcissus* hardy here when I had given them up further south. *Chionodoxa Lucillæ* and *Scilla Siberica* grow and bloom beautifully when protected by a little litter. *Primula denticulata* and *Soldanella alpina*, both requiring protection in England, are strong and healthy after the winter. *Myosotis dissitiflora* and *Digitalis grandiflora*, as well as the common Foxglove, are a surprise to me this spring, knowing that they grow wild in the woods in England, and being biennials which retain their foliage naturally, I felt sure they could not survive.

Prevention of exhaustion by partial shade in summer, and a plan, such as a light covering of litter, in winter, to prevent alternate freezing and thawing, are among the most important considerations in the successful culture of hardy perennials.

Wellesley, Mass.

T. D. Hatfield.

Forget-me-nots.—From March till June Forget-me-nots, grown in cold frames like Pansies and Polyanthuses, attain full perfection. If needed for cut flowers only they may remain to bloom in the frames, but if required for out-door garden decoration in spring, about the end of March or first of April we can lift them with good balls of earth and transplant in some warm, well-sheltered spot. The finer forms of Forget-me-nots have not proved hardy here. No doubt the common marsh Forget-me-not (*Myosotis palustris*) of Europe, also some of the stronger forms of *M. alpestris*, can be naturalized in moist, somewhat shady places in the Northern States, but I have never had any of the varieties of *M. dissitiflora* or *M. Azorica* live over winter as unprotected hardy plants.

Although the Forget-me-nots are all perennials, it is only as annuals that they can be treated successfully with us. True, we may raise a young stock from cuttings or division, but from seed is by far the easiest way. It is a mistake to sow the seeds in spring; spring-sown plants grow large and leafy during summer and many of them die off in fall. Better sow the seeds in July. This will give nice sized plants for winter-

ing over in frames for next spring's blooming. Indeed, the self-sown seedlings that come up so numerous in the beds where the old plants have bloomed, make capital stock to winter over for spring work. Forget-me-nots like good soil and are impatient of drought at any time.

We have white as well as blue flowered varieties of all the common species, and rose-colored forms of some, but a blue Forget-me-not, like a Violet, is more desirable than one of any other color. For cut flowers *M. dissitiflora* is preferable, and both the blue and white varieties are good. Another one that gives great satisfaction is *M. alpestris robusta grandiflora*. It is a little later in coming into bloom than *M. dissitiflora*, but after it does come in it is cut in preference to any other. We have also the new *M. alpestris Victoria*, now in bloom and very beautiful. The plants are dwarf, very compact in habit, and copious in bloom, but while they make admirable specimens either in the frame or spring-garden, their flower branches are not long and ample enough for cut flowers.

W. F.

Onosma stellulatum, var. Tauricum.—This is a neat alpine plant of the Borage family, happily named by Mr. Burbidge the "Golden Drop." It has a semi-shrubby, trailing habit, and hairy, gray-green, lanceolate, evergreen foliage. The flowers are arranged in graceful, arching cymes, 6-10 long, bearing graceful, lemon-colored, deliciously-scented flowers, in succession along more than half their length. It is perfectly hardy in the United States, having been thoroughly tested. It has never, to my knowledge, produced seed, but cuttings taken in spring from plants housed during winter, just after commencing new growth, and with a heel of old wood, which last is absolutely essential, strike easily in a temperature of 50°. The foliage must not be kept damp, so an ordinary glass cutting box will not do so well as the open bench. Young plants planted out in spring make handsome specimens by fall, and if taken up and potted in 6-inch pots will bloom beautifully during the late winter months—February and March. This *Onosma* is both rare and beautiful. It ought not to be rare in this country, for it is propagated far more easily here than in England, where it is much admired, and always sells at a comparatively high price, solely on account of the difficulty in its propagation.

T. D. H.

Mackya bella.—Fine racemes of the handsome flowers of this plant, which botanists now consider a species of *Asystasia*, were shown at a recent exhibition of the Massachusetts Horticultural Society, from the gardens of Mrs. F. B. Hayes, at Lexington. It is a native of Natal, and has not been in cultivation very long, having been introduced into English gardens in 1869 by its discoverer, Mr. J. Sanderson. It is a tall, slender shrub, with virgate branches, producing terminal racemes of pale lilac, campanulate flowers, the throat of the corolla delicately penciled with purple veins. It is a member of the *Acanthus* family. *Mackya bella* is a free growing green-house plant, but it requires special treatment to induce it to flower freely. It should be encouraged to grow vigorously in summer, during which period it requires an abundance of water. During the winter months water should be withheld, and the plant, which loses its leaves, allowed a period of entire rest. Thus treated it will flower profusely along the ends of all thoroughly ripened shoots. *Mackya* is one of those plants which repays the care necessary to induce it to flower freely, and should be more generally grown than it is in this country at present.

S.

Fragrant Herbs for Edging Plants.—Fragrant herbs, as Thyme, Marjorum and Savory, are the delight of many an old country garden, and as they grow so neatly and are so easily raised from seed, there is no reason why we cannot have them here, and in abundance. As edgings to little beds or borders of mixed plants they are neat and appropriate. Both the broad leaved and lemon Thyme are perfectly hardy; Savory and Marjorum seldom live over winter, but they quickly make good plants from seed sown in spring. All the variegated leaved varieties of Thyme are also hardy enough, but must be increased by division or cuttings, as they do not perpetuate their variegation from seed. To these add Lavender, and if desirable its flowers can be cut off. Two other fragrant plants of stocky habit, and well fitted for edgings, are *Calamintha alpina* and *Thymus patavinus*; both are easily obtained from seed.

Strawberries and Birds.—Cat-birds and robins are more destructive to the crop just as the berries are beginning to turn than later on when the full crop is ripe. The best way to circumvent the birds in a small home-garden is to erect a temporary frame around and over the bed, and spread over it a fine-meshed seine or fish net. Instead of a

seine, mosquito netting can be used, but the seine is very much better, as it is no impediment to wind or air, and with it there is no fear of the berries mustering, by being kept too close, moist or warm. Get stakes about eight feet long, place them around and across the beds and about ten feet apart, and drive them about eighteen inches deep into the ground. Then take factory-cut bass-wood strips (each sixteen or more feet long and costing one to one and a half cents) and tack them against the posts on the border of the bed, and from post to post over the top. Then spread the netting over this frame. Sometimes, instead of the bass-wood strips, marlin can be used over the top. This gives a canopy six and a half feet high, leaving perfect freedom for picking the berries. The frame costs very little and the same stakes can be used for the same purpose for many years.

Cut-Worms.—From now till the end of June cut-worms are most destructive and they always are worse in sandy than in stiff clay land. They are especially fond of young beets, cucumbers and melons, but almost any tender young vegetable attracts them. No practicable means of poisoning, trapping or destroying them in any other way than by hand picking has, so far as I know, been discovered. Examine young crops in the morning, and whenever you observe that some of the plants have recently been cut, remove a little of the soil from about the plants and probably the depredator will be found.

The Rock-Garden in Spring.

ONE of the most interesting plants flowering in the rock-garden this week is a form of the Dogtooth Violet from the mountains of Oregon and Washington Territory (*Erythronium grandiflorum*, var. *albiflorum*). It sends up from long, narrow corms, broad leaves, conspicuously blotched with purple, and tall, slender racemes of two to six nodding, lily-like, long-pediceled flowers, which, when fully expanded, are nearly three inches across. The segments are pale yellow, dashed with orange towards the base, with darker orange spots on the interior face. The hardness of this exceedingly beautiful plant has not been fully established here, but if it is planted in an open, well drained situation it will probably flourish.

Several handsome Tulips are now in flower. The most showy of these, perhaps, is *Tulipa elegans*, a form which is known in gardens only, and which Mr. Baker considers a hybrid between *T. acuminata* and *T. suaveolens*. It produces large and handsome bright red flowers, three to three and a half inches long. The base of the segments are beautifully marked on the interior with a yellow eye. They are nearly uniform in shape and are narrowed gradually to a very acute point. This is a very hardy plant which will flourish and increase in any good garden soil. Very satisfactory here, too, is *Tulipa sylvestris*, the European Wood Tulip, a common plant from Norway to the Caucasus. Its handsome, clear yellow, fragrant flowers, one to two inches long, somewhat nodding before they are fully expanded, are borne on tall flexuous scapes. The leaves, of which there are generally three below the middle of the flower stem, are glaucous, smooth and channeled, and often more than a foot long. Less showy than many of the higher colored Tulips, this is an exceedingly graceful and pretty plant. It is perfectly hardy, and blooms freely year after year, requiring no special care or cultivation. A much rarer plant, is the pretty little *Tulipa undulatifolia*, which Mr. Elwes discovered a few years ago on the Bozdagh range of mountains near Smyrna. It is a dwarf plant which is here not over three or four inches high. The leaves are glaucous, the lowest six inches long and one inch wide, the others much narrower, concave on the face with undulate margins. The handsome campanulate flower is bright crimson-red on the inside and dull greenish red without. The segments, which are handsomely marked on the inside, with a large black blotch, surrounded with a bright yellow border, are all gradually narrowed into a long acute point. This is a hardy species here, but it does not grow with any great vigor, and shows no inclination to increase. Another of the fine new central Asia Tulips (*T. Kalpakowskyana*) does admirably here. It is a native of Turkestan, where it was discovered by Dr. Albert Regel, who introduced it into the St. Petersburg Garden. Here the color of the flower is a bright cherry red, with a dull blackish eye, and black filaments and anthers, but it is described as a variable species, sometimes producing yellow flowers flamed with red on the exterior of the outer segments, and sometimes pure yellow flowers with a dark eye and yellow anthers and filaments. This species here

attains the height of a foot, and produces flowers nearly two inches long. It is very hardy and is gradually increasing.

The Painted Trillium (*T. erythrocarpum*) is a far less showy plant than *T. grandiflorum*, but it is a pretty and attractive species well worth a place in the rock-garden, where it seems to flourish, although its home is in the cold, wet woods of northern New England and far northward. The flower is erect with oval-lanceolate, pointed, widely spreading petals, which are pure white, painted at the base with purple stripes. It flourishes in a partially shaded exposure, and requires the same soil and treatment necessary for the other species of the genus.

Persons who value only plants with showy flowers will hardly care to cultivate any of the species of *Asarum* or Wild Ginger—low herbs, with kidney-shaped or heart-shaped leaves, which completely hide the inconspicuous flowers, not unlike, in general structure, those of the well-known Pipe-Vine (*Aristolochia Siphon*). *Asarum Canadense*, a common plant in northern woods, is now in flower, and well fills a shaded pocket in the rockery with a mass of handsome membranaceous kidney-shaped and softly pubescent leaves, which look bright and fresh throughout the summer.

The Virginia Cowslip (*Mertensia Virginica*), an old and well known inhabitant of gardens, is handsome in the rockery or in the mixed border. It is a smooth, very pale, erect plant, one or two feet high, with obovate leaves, and rich, purple-blue, trumpet-shaped, nodding flowers in short raceme-like clusters. This *Mertensia* needs no special care or cultivation, and thrives in all exposures, and in any rich loam. It can be increased by division of the roots, or by seed, which should be sown as soon as ripe.

Dicentra eximia, one of the plants to which the name Dutchman's Breeches is commonly applied, is in flower several days later than the more delicate *D. Cucullaria*. It has bright green, three-lobed, deeply cut, handsome foliage and rather tall scapes, with compound clustered racemes of drooping red or flesh-colored flowers, nearly an inch long, with the crest of the two inner petals of the heart-shaped corolla projecting above the outer petals. This is a coarser leaved plant than the other American species of this genus, and is much more rare, being confined to a few localities in western New York and to the Alleghany Mountains of Virginia. It takes readily to cultivation, however, and has now covered a considerable piece of ground in a rather exposed part of the rockery. It can be easily increased by the division of the subterranean scaly shoots.

Few of our northern wild flowers possess a greater charm than the graceful and delicate little plants popularly known as Spring Beauty, two tuberous rooted species of the genus *Claytonia*. *C. Virginiana*, the more southern of the two species, and easily distinguished from *C. Caroliniana* by its long-linear-lanceolate leaves (those of *C. Caroliniana* are spatulate-oblong, and only one to two inches long), is now thoroughly established here, and is blooming freely in one of the driest, and in summer most deeply shaded parts of the rockery. The pretty, rose-colored flowers in loose racemes close in the evening, but continue to open during several days.

Anemone ranunculoides is a tuberous rooted European species with deeply parted leaves and involucre, and with the general habit and stature of our common wild Wood Anemone, but with rather coarser foliage and clear bright yellow, instead of white or rose colored, flowers. It is an exceedingly pretty little plant, widely distributed, and not infrequently cultivated in Europe, but rarely seen in this country.

Among the few perennial plants of California which find themselves thoroughly at home in eastern gardens, the handsomest, perhaps, is the great peltate Saxifrage (*S. peltata*), which inhabits the beds of rapid mountain streams in the northern Sierra Nevada. This plant, which is one of the largest of the entire genus, sends up in early spring, before the appearance of the leaves, from thick, creeping root-stalks, tipped with broad green stipular leaf-sheaths with membranous pink margins, glandular scapes one or two feet high, bearing dense, branched cymes of handsome, large, pale pink flowers. The leaves which appear later are peltate, round, twelve to eighteen inches across, and are borne on stout, glandular petioles, sometimes two feet high. This fine plant requires, in order to develop all its beauty, a rather moist situation near a brook or along the borders of a pond. Here it will spread rapidly, and soon makes a great mass of foliage, which retains its beauty throughout the summer. It is now in full bloom.

The great interest which has been felt in England of late years in the cultivation of the Narcissus has given rise to several fine seedling forms of the Daffodil (*Narcissus Pseudo-Narcissus*) which command high prices as novelties.

None of these, however, equal the two old varieties, N. Emperor and N. Empress, raised many years ago by William Backhouse, of Walsingham, by crossing *N. Pseudo-Narcissus* with its variety with white perianth-segments, *N. bicolor*. Narcissus Emperor has immense, clear yellow flowers, while those of N. Empress resemble those of *N. bicolor*, although much larger and finer. They are stately and splendid plants, with immense deep-cupped flowers and broad, glaucous leaves, and it is not easy to imagine any product of the soil more beautiful than a great mass of these plants in flower. And yet how very seldom are the finest varieties of Narcissus seen in American gardens, and how few Americans know and appreciate their beauty!

Boston, May 20th.

C.

Notes from the Arnold Arboretum.

THE beautiful Cherry Plum or Myrobalan is now blooming profusely. It is the *Cerisette* of the French and the *Kirschplauwe* of Germany. It is a small tree here, hardly exceeding ten feet in height, with upright, unarmed, glabrous branches, the shoots of the previous year covered with chestnut or yellow-brown bark. The large white flowers appear simultaneously with, or just before, the unfolding of the leaves. They are one-half to three-quarters of an inch across, with lanceolate, glandular, reflexed calyx lobes and ovate-oblong, orbicular petals, and are borne on long, slender, glabrous peduncles. The leaves are ovate-acute, serrate, and sometimes slightly pubescent on the under side when young. The fruit is small, half an inch in diameter, depressed globular, scarlet, or on one tree in the collection bright, clear yellow, and of rather pleasant flavor. The Myrobalan Plum is an exceedingly hardy plant of no small ornamental value, which is very considerably heightened by the fact that, unlike most Plum trees, its flowers and leaves appear at the same time. This tree has long been known in cultivation. Its affinities and its native country even have never, however, been satisfactorily determined. The earlier European botanists, down to the time of Duhamel, supposed that it had been brought from America, but it has no connection with any American plant. Linnæus considered it a variety of the Common Plum (*P. domestica*), from which its glabrous peduncles, globose fruit and earlier flowers distinguish it. Loudon refers it also to *P. domestica*, which he considers to be a cultivated form of the Bullace Plum (*P. insititia*), from which he considered the Myrobalan to be "the first remove." Koch, an excellent authority in questions relating to the origin of cultivated fruit trees, considered it a form of *P. cerasifera*, to which he united the Caucasian *P. divaricata*—a view which finds some confirmation in the reflexed calyx lobes of our plant, and in the fact that its flowers are simultaneous with or precede the leaves by a day or two at most. And lastly, Sir Joseph Hooker, while he adopts Koch's name of *P. cerasifera*, considers "that both *P. cerasifera* and *P. domestica* are cultivated states of *P. insititia*," separating, apparently, the former from the Caucasian species. The flowering branch in his figure (*Botanical Magazine*, t. 5934), derived from the gardens of the Royal Horticultural Society, with precocious flowers, densely fasciated on short lateral branches, a character not given, as he himself points out, in any of the published descriptions of the Myrobalan Plum, can hardly belong to this plant. The Myrobalan Plum, unless Koch's views as to its Caucasian origin are adopted, although cultivated for centuries, is nowhere known in a wild state. A Plum, raised from seed brought from Turkestan and sent to the Arboretum by Max Leichtlin, is identical with the plants of European origin, but whether the Turkestan seed was derived from wild or from cultivated trees is not known.

Prunus Pissardi, a purple-leaved Plum, which of late years has become very common in gardens in this country, is now in bloom, and cannot be distinguished, except in the color of the foliage, calyx, peduncle and fruit, from the Myrobalan Plum. The habit, flowers, fruit and foliage here are otherwise identical in these two plants. *Prunus Pissardi* bears the name of the French gardener of the Shah of Persia, Pissard, who sent it to Europe about 1880. It is said to have originated in the City of Tauris, not far from Teheran, where it is valued for the color of its foliage and for its handsome, blood-red fruit.

The double-flowered form of *Prunus Pseudo-Cerasus* is in bloom. It is a very handsome and hardy Japanese Cherry, resembling some of the double-flowered varieties of the common Cherry, from which, however, it may be readily distinguished by the solitary forked peduncles conspicuously bracted at the base and below the forks, and by the emarginate petals. This double-flowered Cherry is one of the most common and most highly valued garden plants in Japan, where many varie-

ties are known with flowers varying from nearly pure white to pale pink, and with a greater and a smaller number of petals. The single-flowered type of the species, which is pretty generally distributed throughout Japan, and is found also in Manchuria, has not flowered yet in the Arboretum. The double-flowered variety was introduced into Europe from Japan in 1864 by Robert Fortune, and has since been described and figured under various names, of which the oldest is *Cerasus Pseudo-Cerasus rosea-plena*. It is also known as *Cerasus Sieboldi* (*Revue Horticole*, 1866, p. 371), *Cerasus Capronia fl. roseo-pleno* (*Fl. des Serres* xxi., p. 141, t. 2238), and very commonly in nurseries as *Cerasus Watererii*. The best figure will be found in Lavallée's "*Icones*," t. xxxvi. In this country the Japanese Double Cherry is a small tree, rarely exceeding ten or twelve feet in height, with the general habit and appearance of a small Cherry tree. It is very hardy, but does not display much vigor of growth nor flower as freely as the common double Cherry. The deep pink flower-buds and the much paler pink flowers are, however, exceedingly attractive. The branching solitary peduncles sometimes appear clustered, owing to the closeness of the buds upon the ends of stout lateral spurs from the wood of the preceding year; and the effect of the flowers is heightened by their contrast with the handsome bronze-colored young leaves, which are ovate-lanceolate, abruptly acuminate, sharply serrate, six or eight inches long, pubescent when young, but later quite glabrous, the large, conspicuous, three-lobed, pinnatifid, glandular stipules nearly as long as the conspicuously biglandular petioles. The black fruit is described as being the size and shape of a pea.

Prunus Americana, the common wild yellow or red Plum of northern woods and an inhabitant of most gardens in northern New England and Canada, should be mentioned here as an early flowering ornamental plant of very considerable value. It is a small shrubby tree, rarely exceeding twenty-five or thirty feet in height, with thorny, rigid branches, which are now entirely covered with umbel-like clusters of small white flowers with conspicuous scarlet calyx-lobes. Of two forms in the Arboretum, one derived from northern Vermont flowers more than a week earlier than Western plants, upon which the leaves are nearly half grown when the flowers open. The fruit of this species is roundish-oval, yellow, orange or red, and has a pleasant flavor, although the skin is tough and sour. The wild Plum is exceedingly hardy; it grows rapidly and thrives in all soils and exposures; and when well grown makes, at this season of the year, an exceedingly attractive and beautiful appearance.

It is perhaps of interest to note that in the very large collection of Spiræas, *S. Thunbergii*, one of the most beautiful of the genus, is also the earliest in flower by several days. It is a native of Japan, where it is very common throughout the islands, in elevated valleys and on rocky hill-sides in the mountainous districts. This is one of the few plants which is attractive from early spring to very late in the autumn. No shrub produces a greater profusion of handsome flowers year after year; its habit is at once compact and graceful, and the delicate willow-like foliage of a peculiarly bright and cheerful color throughout the summer, in autumn, long after nearly every other deciduous shrub has lost its leaves, turns first to a deep bronze, and then to a brilliant orange and scarlet color. It is well worth planting for the beauty alone of its autumnal colors. And this is true as well of another Spiræa, which is also a favorite in Japanese gardens, although originally a native of northern China—the double-flowered form of *S. prunifolia*, which is more often seen perhaps in American gardens than any species of the genus. It is a very hardy plant, which spreads rapidly, soon making a large, dense clump of rigid, upright stems. It is one of the least beautiful of the Spiræas, however, in habit, and the small, very double white flowers are not handsome, but the colors which the foliage takes on in autumn are splendid in the depth and richness of their scarlet tints. The single-flowered type of this species is wanting in the Arboretum collection. The ends of the branches of both these Spiræas are sometimes killed back here a few inches in severe winters. Otherwise the plants are perfectly hardy, and never fail to flower profusely.

Ribes Gordonianum is in flower. It is a hybrid, raised many years ago in England, between *Ribes aureum* and *R. sanguineum*, and is a handsome and very hardy plant, with the habit and showy racemes of *R. sanguineum*, but the flowers are lighter colored. It is by far the handsomest of the Currants which are perfectly hardy here. Among many American species of this genus now in flower, *R. cynosbati*, the wild Gooseberry of our northern woods, may be mentioned as a plant worth introduction into ornamental shrubberies. It is a compact shrub, which attains, under favorable conditions, a height

of three or four feet, with dark green, round, heart-shaped, three to five lobed leaves, and slender two to three flowered peduncles. The berry is large, armed, like a burr, with long prickles or rarely nearly smooth. The wild Gooseberry thrives in all soils and exposures.

Botanists are familiar with *Andromeda polifolia*, but it is too rarely seen in gardens, although, like many other plants which are only found growing in their natural state in cold, deep peat bogs, where they are often almost entirely submerged in water, this beautiful evergreen takes kindly to cultivation and flourishes and flowers in a garden border as freely as in its native swamps. In cultivation *Andromeda polifolia* makes a handsome, compact mass of foliage two or three feet across, and ten or twelve inches high. The leaves are about an inch long, oblong-lanceolate, dark green above, white on the under side, with the edges conspicuously rolled back. The pale pink or flesh-colored, bell-shaped flowers are produced on long pedicles in short terminal racemes or clusters, and continue to appear during several weeks. *Andromeda polifolia* is widely distributed in North America from Pennsylvania far northward; it is found on the North-west Coast, in northern Asia, in northern and on the high mountain ranges of central Europe. 7.

The Forest.

Tree Notes.

AFTER passing through the intense heat and continuous drought of last summer and the extreme cold of the past winter, many important observations can be made as to its effect on trees in different localities, and as is usual after such severe seasons, the statements will be conflicting, and many cases reported that neither science nor practical experience can account for. In localities where there were seasonable fall rains, trees will be found to have suffered less than where they went into the winter without sufficient moisture at the roots; further than this I have no opinion to offer, for in my experience, each severe winter has had a different effect from the previous ones.

As I spent the past summer and winter on the Pacific Slope I have not had an opportunity to examine the damage done here, but I took a deep interest in the effects produced there, where it was unusually cold for a few days, even to forming ice in some spots in the San Gabriel valley.

Tender herbaceous plants and Palms were injured in some places—the latter very slightly—while they escaped unhurt in others. The varying effect upon exotic trees was noticeable. In one part of the valley I saw the Rubber tree four or five years transplanted and having made a $2\frac{1}{2}$ to 3 feet annual growth, cut back or injured for nearly 3 feet, while in other places a mile or two distant I saw the same tree over 30 feet high, not even injured in the terminal bud.

Two reasons might be given, either of which would account for this difference. The younger tree, irrigated and growing very rapidly, would not be in as good condition to withstand a slight freeze as the more mature tree with a more gradual and better ripened growth. The older tree stood nearer the mountain, consequently the cold north wind could not reach it as it did the tree further off in the valley.

The people in California said they had not experienced such a cold wave for fifteen years; this I could believe, as they had nature for an endorser. Trees always tell the truth and they told it very plainly.

The effect of a hard winter in the desert and on the mountains where nature had full sway was still more interesting. Even among the Sages, Greasewoods, and the numerous shrubs and plants on the desert I could see many that showed the effects of an unusually hard winter for that climate, but as we climbed the mountains the effects were most plainly visible.

The shrubs and plants which had crept up the side of the mountain from the edge of the Desert grew smaller and more shrubby at every step. The western Juniper

and one of the evergreen Oaks, particularly arrested my attention. They had grown on year after year, making a very short growth each year, and holding their leaves, but last winter cut off many years' growth, the foliage still hanging on red and lifeless.

As we ascend the mountain higher and higher one plant after another drops out, until at last we find only the irrepressible Yellow Pine, *Pinus ponderosa*, standing majestically alone, tall, noble shafts, now in masses, again in groups, and then a single tree, with short grass nearly covering the ground in the open spaces. For many miles east and west of Flagstaff, Arizona, these trees form an immense park, and although one species, present so many forms on hill, crag, plain and valley, that the forest does not strike one as being monotonous.

As we gradually descend we find now and then a few diminutive deciduous Oaks, Poplars and wild Roses. The valleys, plains and open spaces intersecting this immense forest are covered with a short species of bunch grass nearly covering the ground, giving them somewhat the appearance of a well kept lawn, as there are no shrubs and few young trees intermixed. The trees stand much further apart than in eastern forests, and as they are entirely free from branches for nearly two-thirds of their whole height, the view extends far in among the tall straight trunks, and is much to be admired, the light cinnamon colored bark having a pleasing effect.

Sheep, cattle and horses are feeding on the grass, and the saw mills are devouring the timber. These forests are already doomed. Few seedlings are springing up to take the place of the older trees, and these will not be able to stand alone and bear the severity of the hot sun and parching desert winds. These forests have stood till now in spite of all the hardships they have had to encounter, but dollars and cents are too much for them! there is money in them, so they must go!

We call the Indians savages! Yet they have more forethought in this case than the white men. They have roamed among these forests from time immemorial, and they have made their mark on the Yellow Pine, for we see that when food is scarce in the early summer, they take strips of bark from the large trees, and eat the mucilaginous part of the immature sap wood, but they never take the strip wide enough to kill the tree, going from one tree to another and not peeling over one-quarter of the circumference of the trunk, so that the tree receives little or no damage.

Robert Douglas.

Correspondence.

To the Editor of GARDEN AND FOREST :

Sir.—As the season approaches in which the bloom of the Ailanthus distresses persons in its vicinity, I am impelled to offer some information with regard to this tree.

It is usually spoken of as a valuable tree for planting, despite the disagreeable odor of its blossoms. Its rapid growth and beautiful foliage make it a favorite with many, and comparatively few are acquainted with its deleterious influence. I am told by a citizen of Boonsboro, Md., that at one time there were many victims to consumption in that place. Physicians were puzzled to account for its prevalence in what was formerly a healthy mountain town. One doctor called the attention of the fraternity to the fact that the cases were in one particular section of the town, and it was discovered that the trees in that end were principally Ailanthus. The fact came out by inquiry that in each case, where there was not hereditary tendency, the patient had first an annual attack of a strange sickness in June, which lasted but a few weeks. The stomach would be disturbed and a peculiar sore throat was one of the symptoms of the temporary sickness. After a few years the throat became chronically sensitive, but was always worse in June, and, eventually, consumption set in.

The particular time in June when this disease prevailed was during the blooming of the Ailanthus. I have been told that legislation was secured in Ohio to prevent the planting of this noxious tree. In my own town there have been marked cases of sickness resulting from propinquity of this tree.

Last summer several families in different parts of town were obliged to call in a physician to treat a sore throat that "went through the family." Several were in bed for more than a week, suffering with nausea, extremely sensitive throat, inability to take any food, inability to sleep at night, a desire to have the air filtered to prevent inhalation of poisonous particles. In each case an *Ailanthus* was in blossom in the neighborhood.

The Hay-Fever Association might obtain interesting statistics if a thorough investigation would be made. Several persons visiting in town were attacked with acute hay fever symptoms, lasting three weeks; but after the bloom was over these symptoms gradually disappeared. These persons had never before been troubled with such affections, nor had they ever before been in the vicinity of an *Ailanthus* in full bloom. A remarkably healthy child was one of the victims, and she did not regain her usual health until the following October.

A hay fever patient for many years had a three weeks' sickness in June, and could not account for the distressing sore throat, influenza and constant nausea. Finally it was observed by friends that this came on during the blooming of the *Ailanthus*. At length hay fever set in, and it was found the latter disease was but an aggravated form of the June attack.

Is it not time that such facts should be published and communities be protected from health-destroying influences?

Hagerstown, Md.

C. V. Tice.

[What we believe to be an entirely unfounded belief in the injurious properties of the *Ailanthus* tree has taken possession of communities in this country at different times and in different places. The flowers of the male tree have an exceedingly disagreeable odor to many persons, and as they produce large quantities of pollen, people liable to attacks of hay-fever would be affected by it, in the same way that the pollen produced by any other plant in equal quantities or by dust would affect them. We have never seen any well substantiated statement of persons supposed to be affected by the *Ailanthus* obtaining relief by the destruction of the trees; and it seems not improbable that the particular cases to which our correspondent calls attention have been the result of malaria or improper drainage or impure drinking water—a belief sustained, in part at least, by the fact that the *Ailanthus* is one of the most commonly planted, and most highly esteemed trees in Paris and other European cities, while its bad reputation, so far as we can learn, is confined to this country. As it is only the flowers of the male plant which are disagreeable, all risk, real or fancied, in planting this tree can be obviated by selecting the female plants only. The influence of the *Ailanthus* upon persons with catarrhal tendencies is a matter of much general interest, and we shall be glad to find room for a statement of well authenticated cases where this tree has been the cause of sickness.—Ed.]

Notes.

Mr. T. S. Brandegee has lately explored Santa Cruz, a small island off the California coast possessing an interesting vegetation which differs in some of its features in a remarkable manner from that of the adjacent coast, and which was first made known a year or two ago by a paper published in the Proceedings of the San Francisco Academy of Sciences, by Mr. Edward L. Greene. The object of Mr. Brandegee's visit to the island was to procure wood specimens of its peculiar trees for the Jesup collection of North American woods in the American Museum of Natural History in this city. This Mr. Brandegee has accomplished, having secured fine specimens of an oak, *Quercus tomentella*, not known within the limits of the United States, except on this Island; of *Lyonothamnus asplenifolius*, a very beautiful small tree attaining a height of forty feet, a representative of a small genus of the Saxifrage family peculiar to this little group of islands, of which a second species, a tall shrub, is known. This plant is interesting as the only arborescent member in North America of a family, which is very widely and generally represented in our flora by humbler plants. The silva of Santa Cruz Island contains also a very handsome arborescent *Ceanothus* (*C. arborescens*), which has not been found elsewhere. *Rhamnus insularis*, and a peculiar form of the mainland *Prunus ilicifolia*, are also interesting trees peculiar to this island. Mr. Brandegee's visit has, he believes, added nearly two hundred species to its flora.

Mr. C. G. Pringle, some of whose interesting sketches of Mexican vegetation have already appeared in this journal, has now started for another long botanical journey in northern Mexico. He will proceed by rail to Lerdo, a town on the Mexican Central Railroad, about three hundred miles from the city of Chihuahua, and then travel by wagon through the Lagoona country practically over the route followed by Wislizenus half a century ago, to Saltillo, Monterey and Matamoras, where he will collect wood specimens of some of the trees peculiar to the valley of the lower Rio Grande, for the Jesup collection. Mr. Pringle then hopes to explore some parts of the Sierra Madre of Nuevo Leon, a region still very slightly known botanically, and then later return to Chihuahua and the region which he visited last year in time to collect the flowers which only appear after the rains of midsummer.

Retail Flower Markets.

NEW YORK, June 1st.

The large sales of small plants for Decoration Day were made at wholesale rates. The supply of flowers continues abundant and prices are low. Baroness Rothschild and Anna de Diesbach Roses are the finest of the hybrids. Selected ones cost 40 and 50 cts. The average run cost 25 cts. American Beauties cost the same. Gen. Jacqueminots are large and have improved during the week in length of stems. They are \$2 a dozen. Bennetts and Madame Cuisins are \$1.50 a dozen. Brides and Catherine Mermets are unsatisfactory in quality. They are 15 cts. each. Perles, Niphets and Souvenir d'un Ami cost \$1 a dozen. Papa Gontiers are of good size and color and they sell for 75 cts. a dozen. Bon Silenes are 50 cts. a dozen. The demand for specimen Hydrangeas has been fair throughout the week. Plants have sold from \$1.50 to \$5. Pink Peonies are plentiful. They bring from 15 to 25 cts. each. Lilac costs 50 cts. a bunch. Mignonette is from 40 to 60 cts. a dozen. Carnation costs 35 cts. a dozen and Pansies 25 cts. The yellow Paris Daisies bring 50 cts. a dozen. They are plentiful and popular. Daisies are 25 cts. a dozen. Violets are small and bring 75 cts. a dozen. Lily-of-the-Valley is out-of-door grown, but large and handsome. It is 50 cts. a dozen. Smilax is 30 cts. a yard. Asparagus costs from 75 cts. to \$1. In most of the baskets made up for souvenirs, shrub blossoms are clustered in one side, while Roses fill the other. Sweet Pea blossoms arrive in small quantities and bring fancy prices.

PHILADELPHIA, June 1st.

The demand for all choice flowers was very heavy until the middle of this week, owing, in a great measure, to the festivities connected with the visit of Mrs. Cleveland. Pansies, the favorite flower of the President's wife, were in especial demand. As a matter of course all varieties of flowers were in request on Decoration Day. Flowers are generally very plentiful now, excepting White Carnations, which still remain quite scarce. Thousands of the wild Daisy are brought into town, and florists report large sales every day. Roses are falling off in color and size, American Beauty being the best now on sale, and fine ones sell for \$5 per dozen. Meteor is the best crimson Rose now; it is brighter in color than Jacqueminot, as seen at this season of the year, and it retains its bright color longer than any other in the same class; as a Rose for summer blooming under glass it is destined to rank very high. Gardenias are becoming more popular as a flower for evening wear. A very few Sweet Peas are offered at \$1.50 per dozen. These dainty flowers are deservedly increasing in favor each year. Corn-flowers are also offered at 50 cts. per dozen; these vary in color from pure white to purple, pink, blue and yellow. Some Forget-me-nots may yet be had, but it is only by careful growing that it is presentable at this late season. General prices remain about as they were a week ago, with a fair demand and plenty of flowers.

BOSTON, June 1st.

As predicted last week, the stock of cut flowers in this market for Decoration Day ran short, and prices were correspondingly high. Roses of the commoner kinds and Carnations were more than double the usual prices. Fancy Roses did not feel the pressure so much. There is no Lily-of-the-Valley in the market excepting the small outdoor variety. Red and bright colored flowers in general are scarce, and bring high prices in the wholesale markets. There has been an abundance of double white Stocks and Spiræa; also a fair supply of white Lilies, all of which were very useful for Decoration Day purposes. One grower here forced a lot of Canterbury Bells, which met with a ready sale, there being no other blue flower obtainable. Its beautiful color and graceful form make it a welcome addition to the small list of really effective flowers available for basket work at this season of the year. Prices of staple varieties by the dozen are as follows: Hybrids, \$6; Jacqueminots, \$3; Mermets, Perles and Sunsets, \$2; Niphets and Bon Silenes, \$1; Carnations, 50 cts.; Lilies, \$2; Lily-of-the-Valley, 50 cts.; Stocks and Spiræa, \$1; Pansies, 25 cts.; Mignonette and Heliotrope, 35 cts. Smilax is of better quality, and worth 50 cts. a string of four to five feet in length. But few corsage bouquets of florists' flowers are worn on the street at present, Apple Blossoms, Wild Violets, Anemones and the like having the preference while they last.

GARDEN AND FOREST.

Horticulture and the Experiment Stations.

AMONG the appropriations made by Congress for the current year is the item of \$685,000 for Agricultural Experiment Stations. By the terms of the act establishing a station in every state, this sum is to be added annually by the Federal Government to the appropriations made by the several states for the same purpose. This liberal endowment ought to mark an era in the country's agricultural progress. We have a right to expect important additions to our knowledge from the labors of the large number of educated men who will be selected for the express purpose of investigating problems connected with the soil and with plant growth. Horticulturists, no less than others who till the soil, are looking towards the new institutions with mingled curiosity and hope, for they have the same need of instruction and an equal right with farmers to expect that their special wants will be considered. Every intelligent gardener and fruit grower is conscious that he is confronted on every hand by problems which he cannot solve, and that his success is menaced by enemies whose attacks he feels powerless to repel. If he knew how to mitigate, in a greater degree, the effects of drought, how to feed his crops more cheaply, how to wage a more hopeful war against the insects and plant diseases which beset him in increasing numbers every year, and how to select varieties that are best adapted to his conditions, his labors would command a more satisfactory reward. The experiment stations were created to answer questions of this kind, and if careful investigation will avail in solving them, horticulture should reap material advantage from the money, time, labor and study expended.

There is no reason why the claims of horticulture should be slighted at any station; indeed, there are special reasons why they should receive marked attention. The products of the orchard and the garden are not inferior in importance to those of the field, and they are quite as indispensable to the general health and comfort. The operations of horticulture are more concentrated than those of other departments in the broader field of agriculture, so that practical cultural questions come home with greater force to the gardener and fruit grower than to the

farmer. Land devoted to horticultural use almost invariably bears a heavier burden of taxation than that devoted to ordinary farming. It requires a greater comparative outlay for labor, for fertilizers and for seed. The injuries to orchard and garden by bad seasons, and by destructive insects and diseases, are more disastrous than those from which the farm suffers, because the crops have a higher money value.

It is gratifying to note that these facts seem to be recognized by the stations, for in the majority of those that have been organized thus far, a horticulturist has been added to the staff of experimenters. The prospect would be more encouraging if the officers selected for this duty were men of wider experience. The natural excuse for appointing untrained men to these important positions is, that the supply of such men is not equal to the demand; that it is impossible to find in the country a sufficient number of skilled horticulturists to take charge of the work in so many stations. But the fact remains that no honest effort has been made to discover men of the requisite ability in this direction or at least no sufficient inducement has been offered to make the position a desirable one. In most cases inadequate salaries are offered for this branch of station work, which means that the Boards of Control consider horticulture of subordinate importance and are willing to take inferior men, with the prospect of inferior work. It is worth noting that in one of the stations, at least, a florist has been appointed, and it may be added that there is no good reason why an industry of such magnitude as commercial floriculture should not be represented in this work. And when we consider how much attention is paid to the cultivation of flowers and plants for ornament throughout the country, this certainly would seem an appropriate field for investigation and popular instruction.

It may be well to warn gardeners and fruit growers not to expect too much from the young stations. To the novice, the making of experiments may seem an easy task, but experience proves that few things are more difficult than the gathering of accurate and helpful information in this way. The highest skill is demanded in every operation, and with this must be united close observation and a faculty for gathering in every related fact for purposes of generalization. The experimenter must not only have unswerving intellectual honesty, but a trained ability to weigh evidence and a cool judgment that is never swayed by a preconceived hypothesis. And yet he must be adventurous in constructing theories, for mere machine-like accuracy in weighing and measuring can never take the place of the creative genius which originates hypotheses. A great discovery in science was once well characterized as an "inspired guess." But it is only the mind well equipped by study and in perfect command of all its resources that invents a sound theory so easily and naturally that it seems to be only a lucky guess. With so many raw recruits just entering the experimental field, it will be fortunate, indeed, if costly mistakes are not made. For a time, at least, it may require greater wisdom on the part of the practical cultivator to separate the true from the false in the bulletins borne on every mail than was exercised originally in preparing them. But a beginning must be made, and while we need not be over-hopeful of immediate results, it is safe to anticipate signal advantage to horticulture and agriculture from the stations, when their work is thoroughly organized and systematized. Capable Directors and their assistants will become more useful with larger experience. Under the searching criticisms of the press incompetent men will be weeded out and the work will at last fall into the hands of those who will prosecute it with wisdom, devotion and enthusiasm. It may require years of patient waiting before the new stations become as helpful here as they have proved in Europe, but some of the older ones already justify every reasonable hope of their founders. In future numbers we hope to indicate some of the more promising lines of investigation which should be pursued in the interests of horticulture.

ACCORDING to the English papers an extraordinary piece of tree planting has been undertaken in Wales. On the side of Moel Rhiwen mountain a loyal enthusiast, Mr. Assheton Smith, is inscribing in letters formed with trees, and each six hundred feet in length by twenty-five feet in width, the words "Jubilee, 1887." The first trees were planted with much ceremony on the Queen's jubilee day; 630,000 trees will be needed to complete the giant inscription, and two hundred men are constantly employed upon the work. It is not pleasant to think what an amount of good planting might have been accomplished if a different direction had been given to the expenditure of all this energy and money, which now will go merely to disfigure a whole country-side with a colossal monument to wastefulness and bad taste. And, what is worse, so liable is a modern nation to be led astray by any conspicuous novelty, Mr. Smith may find many admirers, and, perhaps, an imitator or two—a supposition justified in the fact that no English journal which we have seen has uttered a protest against his scheme.

No planting as bad as this has yet been done in America, and it is doubtful, perhaps, whether anything quite so bad in disfiguring nature has ever been deliberately attempted before anywhere.

Tree-planted letters, however, are not a novelty. In the hunting-park at Moritzburg, near Dresden, there may still be seen the initials of a certain seventeenth-century prince done in evergreen trees, clipped in such a way that their height increases from the base to the top of the letters, which are seen, therefore, as though laid on an inclined plane. But these letters are only some thirty feet in length and are hidden away in a corner of the park. When this device was made, formal planting, the clipping of trees and puerile gardening tricks of many sorts were in universal use; and, placed as it was, it had at least the merit of being unobtrusive. It has remained for the nineteenth century, which prides itself upon a truer love for the genuine beauties of nature, to disfigure a whole mountain-side and a lovely landscape with a gigantic inscription which can be read for miles.

The Pine Barrens in May.

IT is the last of May, and very late in the Pines. The broad-leaved Laurel (*Kalmia latifolia*) is only just beginning to unfold its many-flowered corymbs of rose-colored and white blossoms, making the waste places gay and brilliant. And its small relative, the Sheep Laurel, is opening its deep crimson-colored flowers. In some places it has taken possession of the ground to the almost entire exclusion of other plants.

The Stagger Bush (*Andromeda Marianna*) is in full bloom. Although not as showy as the Laurel, yet its large clusters of pure white, waxy-looking bells make it very attractive. Another shrub of this genus, *A. ligustrina*, is also in flower, as well as its near congener, *Leucolhoë racemosa*, with long one-sided racemes of white flowers.

The Sand Myrtle (*Leiophyllum buxifolium*), a little evergreen shrub, with umbel-like clusters of flowers, is charming. The small petals are pure white, but the ten exerted purple-pink stamens give it considerable color, while the dark, shining leaves make an effective background for the flowers. In the more moist places *Itea Virginica* is abundant, and covered with racemes of small white flowers. But the crowning beauty among these wild shrubs is the Fringe-tree (*Chionanthus Virginica*), which here and there are so white with their graceful, drooping panicles of flowers that at a little distance they look like snow-banks.

The heavy odor of the Swamp Magnolia proclaims its presence on every side, and those who like the fragrance are fortunate, as the flowers are very beautiful amid the deep setting of the shining leaves. The Swamp Maple,

growing alongside, is also pretty and effective with its long, swaying pedicels and winged scarlet fruit.

The Holly (*Ilex opaca*) is shedding its winter leaves, and sending out new ones, which have not yet taken on the glossy green that characterizes them later in the season. The bright red berries are still scattered over some of the trees, while the new shoots are full of clustered flowers, giving promise of abundant berries for next Christmas time. Its relative, the Ink-berry (*I. glabra*), is also in bloom, while retaining its thick evergreen leaves and black berries. And another shrub of this genus, the Black Alder (*I. verticillata*), is likewise holding its bunches of scarlet berries while being crowned with new leaves and flowers.

In the distance I see great clumps of Mistletoe, and on a near approach I find this, too, covered with flowers amid its white berries. The flowers are greenish yellow, nearly the color of the thick, persistent leaves. The Sweet Gum trees, on which it has made its home, have a forlorn, prematurely old look, as if they did not enjoy the burden imposed upon them. The Shad-bush (*Amelanchier Canadensis*, var. *oblongifolia*), together with most of the Blueberries, are nearly out of bloom, and forming fruit for a plenteous harvest.

Many of the herbaceous plants are now in the first flush of beauty. Among the most notable is *Xerophyllum asphodeloides*, which sends up from a thick tuft of evergreen, grass-like leaves, from one to eight or ten flower stems, surmounted at the top with a compact raceme of beautiful white flowers. The Pitcher-plant is also unfolding its singular deep purple flowers, and its strange, pitcher-shaped leaves have withstood the frost of winter, and are still fresh and bright.

The Pine Barrens also nourish some lovely Orchids. The delicate *Arethusa bulbosa* is now in bloom, and the low Moccasin flower (*Cypripedium acaule*), and these will be succeeded by other species until frost comes in the fall.

And here, too, I find the pretty little Star-flower (*Trientalis Americana*), with its pure white stars standing above the whorl of pretty leaves. It is called a northern plant, whose habitat is cold damp woods, but here it is fresh and vigorous, with stems bearing three and sometimes four flowers. The slender Blue Flag (*Iris Virginica*), with leaves no wider than some of the grasses and sedges that surround it, is just beginning to open its fine, delicately formed flowers. And the little heath-like *Hudsonia tomentosa* is thick in the more sandy places—scarcely allowing room to step—and is covered all over with bright yellow flowers, that are too pretty to crush with the foot. And here is the Cucumber-root (*Medeola Virginica*), the stem clothed with white wool, and bearing two whorls of leaves, and just beneath the upper one small recurved purple flowers.

Most of the plants herein mentioned can be easily cultivated. I have a nook in my garden devoted to them, where they are growing finely. One side of the bed is bordered with *Xerophyllum*, which blooms freely. One plant has eight flower stems, others four and five, making a beautiful display. The Pitcher-plant also does well in an artificial swamp—five flowers on one plant. This, and other bog plants, are more beautiful here than in the wild swamps, as they never suffer from drought as they often do in the shallow bogs—the home of their birth. *Mary Treat.*

May 30th.

Suggestions for the Improvement of Cemeteries.

WE shall be able, perhaps, to realize more quickly and clearly the direction in which to seek for improvement in cemeteries by following a more practical and out-of-doors method of investigation than by consulting an art-library. Let us, then, consider the simplest possible example and see what suggestions it may offer for our guidance in more complex and more extensive cases.

Some of us, perhaps, may remember to have seen a cluster of many family graves in an uncultivated nook

or dell of an old farm, where some of the less commercially valuable, but equally beautiful, original timber trees have been allowed to grow undisturbed, till their very size makes the few brown-stone grave-slabs seem modest and nestling to the ground, and where, the cattle having been kept out, the wood violet and other shy wild plants add their delicate charms, while they also mark the peaceful seclusion of the spot. Such simple and yet dignified rural furnishings are in harmony with the purpose to which the place is dedicated and to the feelings of the sympathetic visitor to it, and leave the imagination free to conjure up, if it will, romantic visions of the past. In such a spot the thought might easily occur to one that here was indeed a restful place in which to have laid away the mortal remains of a few of those weary human beings whose life struggle it was to subdue nature to their own aims, and who yet finally succumbed to her and whose remains became a part of her.

How much more appropriate to their lives are such graves, with such surroundings, than they would have been in some great cemetery, where their modest little grave-stones would have been put to shame by scores of big, staringly white Egyptian obelisks, broken topped Greek columns, Roman urns, weeping Italian angels, Renaissance canopies, Gothic spires, and all the other kinds of showy monuments, and where all restfulness and seclusion are annihilated by rows upon rows and scattering swarms of factory-made, white marble grave-stones, all set up on edge so as to be as conspicuous as possible and looking as if they would be heaved out of plumb by every frost. Such stones have, in fact, the very unmonumental quality of being in a state of unstable equilibrium. And as if all these white monuments and grave-stones were not enough to frighten Nature into submission, innumerable fences are added, mostly of the sort which may be described as the "this-is-the-most-show-you-can-get-for-your-money" cast iron fence. And, as iron rusts into a color which is somewhat harmonious with nature, such a catastrophe is carefully avoided by painting all iron work a gloomy black, or vivid white, or by gilding it, like a cresting over a chromo tea store. The managers of cemeteries seem to be proud of these private fights with Nature, and do all they can to aid and abet them with their ribbon gardening and by planting all the most artificial looking specimens of "nature's bright productions" that skillful nurserymen can induce to grow. They have no limiting rules as to showiness, but are only too glad to sell lots to those who will spend most in making a show that will advertise the cemetery.

The few who feel dissatisfied with this state of things should organize new associations for forming and maintaining truly rural cemeteries. They should have other and higher ideals in their minds, and should limit themselves and their successors by strict rules adapted to secure the desired result—so far as rules can do so. If they allow monuments at all, they should use the same care and discrimination that a "hanging committee" do in limiting and arranging the works of art that necessity compels them to place so cruelly close together in a gallery. But they ought to go further than this; they should encourage, if not require, burials to be made with no monuments at all at the graves beyond the merest end of a dark colored stone that will serve to permanently mark the spot and to carve a family name upon. All other necessary information in regard to persons buried in the cemetery can be given on slabs in a memorial wall at the entrance, or by written records. They can provide halls, galleries, or loggias in which to place bas-reliefs and other sculptures of suitable character and size, and thus avoid all monuments scattered promiscuously through the grounds. As for planting, it should be done according to a comprehensive scheme, and the choice of plants had, probably, best be limited to such as are native in the region; not that this is essential, but in order not

to leave too much to the discretion of zealous, but indiscreet persons, who are constantly making their selections for planting upon the supposition that what is good under some circumstances must be good always. They should establish a rule limiting fences to those that are necessary, and requiring these to be in conformity with some general scheme devised with due regard to harmony with and strict subordination to nature. There should be a like subordination to nature in all other necessary artificial constructions, such as retaining walls, bridges, roads, walks, gutters, steps, guide posts, vault fronts, and so on. They should avoid formality and artificiality in all things and at all times, for they should remember that they have set out to make a rural cemetery and not an architectural one.

J. C. Olmsted.

Brookline, Mass.

The Cultivation of Huckleberries.

Gaylussacia and *Vaccinium*, genera belonging to the Huckleberry tribe of the *Ericaceæ* or Heath Family, comprise a hundred or more species found in various regions, but chiefly in America, where they are known as Huckleberries, Blueberries and Cranberries. Owing to their great abundance, few attempts have been made to improve any of them except the Cranberry. The time will come, however, when every small-fruit garden will have its improved varieties of Blueberry or Huckleberry, as well as its Strawberries and Raspberries. No good collection of these plants, so far as I know, exists in any of the European gardens, and, apart from the collection started at the Arnold Arboretum, I know of none in America. Indeed, so difficult has the cultivation of these plants been considered, that any record of success in the attempt has usually been doubted.

The growing of Huckleberries and Blueberries from seed requires close attention, and can hardly be carried on successfully without a green-house or frame. The best soil to use for them is sand and loam in equal parts, care being taken that the sand is free from clay or iron.

Shallow earthen pans are better for the seed than boxes, as there is less danger from fungus, but after the first transplanting boxes may be used.

As soon as the fruit is received it should be macerated in water for several days, so as to separate it from the pulp, and then washed clean. If early in the season, seeds of the early varieties may be sown at once, and will come up in a few weeks, but as the plants will make little growth, they will need careful handling to keep them over the first winter. It is better to wash out the seed and mix with fine moist sand, and keep in a cool pit or frame until the days begin to lengthen, say about the middle of January. Then prepare the seed pans or pots and insure free drainage by using sphagnum or coarse siftings of peat. Firm the soil well and give a gentle watering with a fine hose. When the soil has settled, scatter the seeds thickly and evenly over the surface and give the lightest possible covering. Then add a layer of fine sphagnum, syringe lightly, and set the pans in a temperature of 60° to 65°. After sowing, if the seed is not allowed to become dry, it will usually come up in from five to six weeks, although I have known it to lie in the ground a year and then germinate. The pans should be examined now and then, and as soon as the seed shows signs of germination the coarsest of the moss should be removed. When the plants have made the first rough leaf they should be pricked off thickly in shallow boxes and fresh soil prepared and drained as for the seed. They should be syringed every day and kept growing in a high temperature and moist atmosphere. As soon as they have covered the ground they should be again transplanted. After the third pricking out, if everything has been carefully attended to, they will be growing strongly and will need more air and less moisture, to harden them off gradually. The frequent transplanting in fresh soil each time keeps the plants from damping off and encourages good root-growth. About the 1st of September they can be removed to a cold-frame or pit in some sheltered situation, where they should have plenty of air every pleasant day, but should be covered at night to keep them from frost as long as possible, so that they may become ripened before going into their winter quarters. As winter sets in they should be covered with moss and shutters, and will only need airing once or twice a month for a few hours to guard against fungus, which will start even in a cold-frame if kept long without air. About the first of May they can be planted in prepared beds of peaty soil or a light sandy soil of good depth. If dry weather sets in they will require a good

syrring toward evening, as the plants are not deeply rooted yet, and delicate rootlets are soon destroyed if allowed to dry. After the middle of August the syrring may be discontinued, so that the plants may ripen well. When freezing weather comes the beds should be mulched with Pine needles, Oak leaves, or other similar material, to keep the plants from heaving. After the second year they are transplanted to the nursery and need only ordinary care. When finally removed they will be found to transplant with the greatest of ease, and no perceptible loss.

The Huckleberries and Blueberries can also be propagated from cuttings of the underground stems or stolons which are found on many varieties. These can be taken up in the autumn, cut in lengths of two or three inches, planted in boxes of sandy peat or loam, and kept in a cool pit or house away from severe frost until about the 1st of February. They then require a gentle heat and moisture until they start. When they have made a good growth they should be hardened off and treated as other hard wood plants, but, like other members of the Heath Family, they cannot endure saturation while growing under artificial treatment.

These plants can also be grown by layers, by bending down the branches and tonguing, as with other hard wood plants. A good moist mulch of moss around the young layers will accelerate the rooting. I have not as yet propagated them from cuttings or grafting, but I see no reason why this should not be done with cuttings of the young wood, just as other Ericaceous plants are propagated.

I should advise those not having green-house facilities to select healthy young plants from an open pasture if possible, not more than a foot high. Much larger ones can be transplanted, but greater care is needed for success. Take them up early in September and plant them firmly and thickly in a well prepared bed, which should have a good share of sand and peat with the loam. Protect well with a heavy mulch, and during the first summer keep them well watered when the weather is dry. If the ground is kept well stirred and clean, by the second spring they will have an abundance of fine roots, when they can be transplanted where they are to remain with the greatest ease and safety. I have handled thousands of them in this way with perfect success. My reason for transplanting early in September is that new roots are then formed before winter sets in, and if well mulched, as stated above, they are ready for a strong start in the spring. While they will do well in any good soil not overcharged with manure, I find they give more satisfaction if a few inches of peat or leaf mold is spaded in with the soil. On poor light lands a top dressing of well decomposed cow-manure would be beneficial. Strong, rank manure should be avoided, as most plants of this family resent its use.

The following are a few of the best known North American species: The Black Huckleberry (*Gaylussacia resinosa*) is a shrub from two to three feet high, with dull, reddish yellow flowers and sweet, crisp, globular berries of a shiny black color. The fruit is firmer than that of other species, which makes it of more value as a market berry. But it is much more difficult to start and is not so easily transplanted as the Blueberry. Of several marked varieties, one has very sweet, pear-shaped berries, with blue-black bloom; the common name of "Sugar Plums" has been given to them. Another variety has glaucous leaves, and berries covered with a glaucous bloom. A third has large bluish berries, with rich flavor, and a fourth has white berries, which are much more delicate to the taste and bring in market more than double the price of the common varieties. Large areas of Huckleberries now grow wild, and yet the crop is diminishing each year, and it would be prudent to prepare for future supplies. Superior varieties could be originated, and they might be made as profitable, no doubt, as other small fruits. Naturally, the Huckleberry is found in open woods and dry rocky hills from Canada to Georgia.

The Dangleberry or Tangleberry (*G. frondosa*) is easily distinguished from the common Huckleberry by its large pale green leaves, which are glaucous beneath, and its loose drooping racemes of flowers often from two to three inches long. When neither in bloom or in leaf, it can be distinguished by the reddish yellow wood of the new growth, and the ashy gray bark, often peeling from the old wood. The fruit is large and has a blue bloom. It ripens much later than the former species and is more acid in flavor. It is not common in eastern Massachusetts, except along the seashore. I have never found it more than three or four miles from the coast. It is a much stronger growing shrub than *G. resinosa* and of a more open, branching habit, often being found more than four feet high. Farther south it comes to greater perfection and is considered superior in flavor to other varieties. It is native from

Massachusetts to Florida. It grows much more readily in cultivation than *G. resinosa* and might be improved like the other species by selection or hybridization.

The Bush Huckleberry (*G. dumosa*) is a small shrub not more than two feet high and not as common in eastern Massachusetts as the other species. I have usually found it in sphagnum bogs with *Andromedas* and *Cassandras*. The leaves are narrow and shining above. The flowers are in short racemes and bracted. The berries are of a good size and shiny black, not abundant and rather insipid, but not unpleasant to the taste. Plants transplanted into a deep moist soil at the Arboretum only two years planted are doing fairly well.

The Deerberry, or Squaw Huckleberry (*Vaccinium staminium*), is a neat bush two or three feet in height, with slender green branches which afterward turn brown. The foliage is often two inches long and one wide. The racemes of flowers are conspicuous on account of the long yellow anthers projecting beyond the spreading corolla, which is pure white. Few of our hardy Ericaceous plants are more beautiful in bloom, and it is well worth a place in every garden if only for cut flowers, which appear like fairy bells. The berries are greenish white or dull red and can hardly be called edible. The fruit from North Carolina is much larger than that grown in Massachusetts. Its range is from Massachusetts to Florida.

The High Bush Blueberry (*V. corymbosum*) forms handsome clumps of shrubbery from four to ten feet high in deep swamps and moist woods, but seldom reaches more than four feet in open pastures. The young branches are usually yellowish green, turning to a light gray when old or much exposed, while the bark on old stems becomes rough and peels off in shreds. The leaves are narrow, mostly egg-shaped, often purple at the time of flowering, but afterwards becoming much broader and coarse veined. The flowers are large, white, bell-shaped, and borne on the extremity of the branches of the previous year's growth. They appear in May and early June, and the fruit is ripe from August to late in September. The latter is variable in shape, size, flavor and color. Of many well marked varieties, one has large black fruit of a pleasant acid which seems exactly the flavor to add to a bowl of new milk. Another, a large blue one, has a delicate sugary flavor. I chanced upon a bush in East Foxboro last summer which was twelve feet high, loaded with berries of a beautiful blue, rich, juicy, and half an inch in diameter, while some were even larger. In this swamp ten or twelve good forms of fruit might have been found, and by careful selection and hybridization there is no reason why the High Bush Blueberry should not become an excellent and abundant fruit, as it is more easily cultivated than any of the others. An acquaintance in Cambridge planted a few, some years ago, and now he has all the fruit he needs during the season, while during the rest of the year nothing can exceed the beauty of the shrubs. A dwarf form of *V. corymbosum* which rarely grows more than eighteen inches high has large fine abundant fruit of a bluish black color.

The Low Blueberry (*V. vacillans*) is a shrub from one to three feet high with a yellowish green stem and glaucous leaves, usually growing on high rocky ground and at the edge of woods. It bears an abundance of large sweet berries which are chiefly covered with a blue bloom, though I have found black varieties. The fruit and flowers are formed at the extremities of the last year's growth, which is from one to four inches long without leaves, so that a large part of the plant seems leafless. The ends of the branches are covered with fruit, however, which can be stripped off by the handful. As it is very prolific, the flowers of this species in May look much richer and more abundant than in any of the others. The fruit is ripe from late July to September. This plant is well worth cultivation as an ornamental shrub, and for its valuable fruit. I saw a white variety of it some years ago in Plymouth, Massachusetts.

The Low Blueberry (*V. pennsylvanicum*) is a low growing shrub seldom exceeding a foot in height with narrow shining leaves and white flowers in early spring. This is found in immense beds in Pine woods and rocky, shady places, often covering great areas of rock when there is not more than an inch of soil, with a carpet of rich soft green which in May and June is covered with white and pale pink blossoms and in July loaded with its delicately flavored fruit. This is the first Blueberry to ripen in New England, and the early crop brings such prices that the children earn many a dollar by picking it, besides the fun of going a-berrying. These berries are somewhat easily bruised, but if carefully handled can be carried a long distance. There are several recognized varieties of this species. One is black fruited, flat at the end and much finer than the species. This might be made profitable as well as

ornamental, as it will grow under the drip and shade of trees, and on the poorest soils.

The Canadian Blueberry (*V. Canadensis*) is a dwarf shrub with light green wood seldom exceeding a foot in height, and resembling *V. Pennsylvanicum*, but with broader and more downy leaves. The fruit is blue-black and ripens later than the common Blueberry. It is not common in the State of Massachusetts, but through Vermont and parts of the British Provinces it is more plentiful and is sent in large quantities to Boston markets after the home supply is exhausted.

V. uliginosum is a low spreading shrub with glaucous foliage and blue berries which are edible but not abundant. It is a native of the high New Hampshire Mountains and northward. It is also found in northern Europe and northern Asia. It is growing well at the Arboretum.

V. cespitosum is a minute alpine variety not more than one or two inches high.

The Cowberry, or Mountain Cranberry (*V. Vitis-Idea*), is of neat habit, resembling miniature Box, but of a darker and more glossy green. The woody branches springing from underground shoots or stolons soon make a solid mass of rich green foliage not more than four or six inches high. The flowers are of a rosy pink, and the berry dark red and acid. They make, with sugar, a rich jelly or sauce for meats or desserts. The plant is found only in one or two localities in Massachusetts, but is more common on high mountains of New Hampshire, and in the Province of New Brunswick it covers immense tracts and in the markets of St. Johns I have seen the berries for sale by the barrel. It is also a native of the high mountains of northern Europe, where the fruit is used for jellies. It does fairly well in cultivation in a peaty moist soil.

The Common Cranberry (*V. macrocarpon*) is found in large beds on low grounds in almost every part of New England. It is a prostrate evergreen creeping along the earth or moss by fine roots. The flower stems are thrown up on slender branches, and are pale red, later becoming variegated. The fruit, usually bright red, is sometimes black. It varies much in size, shape and color, is round, pear-shaped or egg-shaped. Many varieties have been selected by the cultivators, some of which are nearly an inch in diameter. The growing of Cranberries has become in many parts of the country a great industry. Hundreds of acres of Cranberry bogs are now in preparation at an expense of from \$100 to \$300 an acre. Even at that price the bogs yield a good profit, often in the third year, as many as five hundred bushels being sometimes gathered from an acre of well prepared land.

The Small Cranberry (*V. Oxycoccus*) is a much smaller plant in leaf, fruit and flower. It is usually found in cold bogs. The fruit is used for the same purposes as the other Cranberries, but is seldom gathered when *V. macrocarpon* can be had. It does fairly well in cultivation, but except for botanical purposes it has little interest.

The Erect Cranberry (*V. erythrocarpon*) is a tall shrub, with reddish nodding flowers, and large black, very juicy insipid fruit. It comes from the mountains of North Carolina, and south. This shrub is scarcely hardy in the Arboretum. We have also *V. Myrtillos*, *V. Arctostaphylos* and *V. ligustrifolia*.

Other varieties that we have not yet tried may prove of interest, such as *Gaylussacia brachycera*, a very rare, dwarf, evergreen species from the mountains of Pennsylvania and Virginia; *Vaccinium hirsutum*, a small plant from the mountains of North Carolina, with neat foliage and dark colored fruit, and several others.

New or Little Known Plants.

Amelanchier alnifolia.*

DOUBTLESS hundreds have seen and admired the bloom of our eastern Shadbush among the bursting foliage of the spring woods to one who has seen and tasted its fruit. For some unexplained reason the flowers of this species, at least in certain sections of the country, are rarely fertile, and in my boyhood the Juneberry, as the fruit of the Shadbush was called, was like a myth to me until a young tree well laden with ripe berries was brought home by a neighbor as a curiosity. The peculiar flavor of the fruit as then experienced lingers yet in memory. With the western representative of the genus, *A. alnifolia*, the case is different. It fruits abundantly, and in the region from the Rocky Mountains westward, where the supply of berries and fruits is limited to a few Raspberries, Buffalo-berries, Haws, scarcely edible Currants and the Wild Cherry (of all which the last is really the only one deserving mention), the abundance and excellence of this fruit goes far in its season to make up the deficiency.

In a note which I find in the Gray Herbarium, written many years ago by the missionary, Rev. Mr. Spalding, it is stated that hundreds of bushels of these berries were dried every year for food by the Indians of the Clear Water region in Idaho.

This shrub, which is here figured, grows to a height of 6 or 8 feet, with an erect somewhat tree-like habit and dark green foliage. The leaves are rather thick and vary much in form, but are generally rounded or broadly elliptical, mostly very obtuse, or truncate, or even retuse, and coarsely toothed usually only near the summit. The flowers are usually large and showy, in short racemes, and the dark purple fruit is 3 or 4 lines in diameter, with few seeds. It is found in the mountains throughout the West, at wide extremes of altitude, from British America to California, Utah and Colorado, and from the Pacific to the Rocky Mountains, Minnesota, and Lake Winnipeg. S. W.

Fig. 34.—*Amelanchier alnifolia*

Plant Notes.

Selaginella Pringlei, Baker.

THIS new rosulate *Selaginella* (Nos. 271 and 886 of *Pl. Mex.*, wrongly referred to *S. cuspidata*, Spring.) is abundant with *S. leptophylla* in gravelly soil of dry calcareous bluffs and ledges of the barer mountain ranges of Chihuahua. It is as much a "resurrection plant" as is its associate, which, indigenous along our south-western border, has been often described and is well known. As the atmosphere and soil become dry, these plants take the form of a ball by the curling inward over their centre of their frond-like stems. Then the cañon sides present an unsightly and desolate appearance as though strewn with dead rubbish; but an evening shower suffices to transform them into lovely banks, thickly spread with the green mats of these plants, circular in outline and of exquisite design. The new species is very distinct from its well-known congener, being of a lighter green, and having softer

* *A. ALNIFOLIA*, Nutt. in Journ. Philad. Acad., vii. 22. Glabrous or often more or less pubescent; leaves broadly elliptical or rounded, obtuse at both ends or rarely acute, often somewhat cordate, coarsely toothed usually only toward the summit; racemes short and rather dense; petals an inch long or less, narrowly oblong; fruit purple.

stems and spinulose leaves. For the embellishment of rock-work in regions where they would not be exposed to severe frost (though they might in colder countries be pulled up and laid away for the winter on a dry shelf), these radiate-stemmed Selaginellas may be made of great service.
C. G. Pringle.

No true Water Lily (*Nymphaea*) was known to the flora of Pacific North America until June of last year, when Mr. John B. Lieberg discovered in a pond in northern Idaho a very pretty and distinct species that Mr. Thomas Morong, in the May issue of the *Botanical Gazette*, describes under the name of *Castalia* (the name which some botanists are anxious to see adopted in place of *Nymphaea*) *Liebergi*. It is a diminutive plant with white odorless flowers about an inch and a half in diameter when fully expanded. Mr. Morong points out the resemblance of the Idaho plant to *Nymphaea pygmaea*, a native of Siberia, China and Japan. The extension of this genus into western America is a fact of no little interest from the point of view of geographical botany.

A Sonora Hillside.

THE illustration on page 187 will give our readers a pretty accurate idea of the general appearance of much of the desert country in southern Arizona and the adjacent parts of north-western Mexico. It represents one of the low, granite foot-hills of the Sonora Mountains near the head of the Gulf of California. This is one of the most barren and inhospitable regions of the North American Continent. For fifty miles inland from the Gulf, sandy plains, which near the coast are shifting sand-dunes, alternate with numerous chains of low mountains trending with the coast—vast piles of volcanic rock, sprinkled over with a little fine soil. These desert mountains are absolutely treeless except in occasional cañons, where a little soil, washed down from the slopes above, has enabled the Mesquit and the Ironwood (*Olneya*) to obtain a foothold, and to drag out a miserable existence. The base of these forbidding mountains, and the lower hills and broad, gently swelling *mesas* which support them, are covered with more soil than the higher slopes, and produce a striking and extremely interesting Cactus vegetation. Mr. Pringle, almost at the peril of his life, and only with great suffering to his animals from scarcity of water and absence of forage, made a careful botanical survey of this region during the summer of 1884, and our illustration of a Sonora Hill is from one of a series of photographs which he was able to make during this journey. The tall, grotesquely branching cylindrical plant scattered over the hill is the *Suwarrow* of the Mexicans (*Cereus giganteus*), the tallest of the Cactus family, often exceeding a height of sixty feet, with a diameter near the ground of two feet. The handsome white flowers appear only at the very top of the tall shaft, and quite encircle the summit. The skeleton consists of a number of stout perpendicular ribs, only slightly attached together, and composed of hard, solid and durable wood, upon which time and exposure seem to make very little impression. They may be found scattered about on the desert, where the plants have died or been cut by Indians in order to secure the edible fruit. The fleshy covering soon disappears by decay, but the skeletons remain hard and sound. They afford the best material produced in this region for the rafters of huts or for small posts, and the Mexicans gather them in large quantities from the desert for these purposes. The stiff, rigid clumps among the *Suwarrow* on the hillside are plants of another large Cactus, widely branching at the ground from a single crown—*Cereus Thurberi*—one of the interesting discoveries of Dr. George Thurber, who, as botanist attached to the United States and Mexican Boundary Survey Expedition, first explored what is now the extreme southern portion of Arizona, and parts of Sonora. Although closely

allied to *C. giganteus*, *C. Thurberi* is a much smaller plant, the clustered stems rarely rising to a greater height than fifteen feet. The flowers, like those of *C. giganteus*, are greenish white, but the tube is narrower and more elongated, and they appear, not at the summit of the stem, but in a circle about one foot below it; and the fruit, like the ribs of the stem, are thickly beset with clusters of black spines. It was found also by Mr. Schott in Sonora, shortly after its discovery, but from that time (1851) was not seen again in a wild state by any botanist until Mr. Pringle visited this part of Mexico in 1884. *Cereus Thurberi* was at one time in cultivation from seed brought home by Dr. Thurber, and it may still be found, perhaps, in some of the European collections. There seems to be no record, however, of its flowering in cultivation. The large Cactus with tall, cylindrical stems in the lower left-hand corner of the picture is another *Cereus* (*C. Schottii*), a plant which, from a widely branching or stoloniferous base, throws up numerous stems, ten to fifteen feet high, and six inches in diameter. They are five to seven angled, armed in the sterile part of the plant with short, and on the fertile upper branches with long, pendulous spines, which form a reddish gray beard, in which the flesh-colored flowers and oval, purple fruit are hidden. There are scattered over the hillside, too, numerous dwarf specimens of a leguminous plant, *Parkinsonia microphylla*, which, under more favorable climatic conditions, sometimes attains the habit and the height of a small tree, and of *Bursera microphylla*, both plants able to put forth and maintain their minute leaves during a few weeks under the burning Mexican sun, which here so heats the rocks in summer that the human hand cannot bear contact with them. The large bush in the lower right hand corner is a small plant of the so-called Green-barked Acacia, the *Palo Verde* of the Mexicans, one of the most conspicuous plants of the desert, and, next to the Mesquit, the most familiar, perhaps, to travelers in the whole Boundary region from Texas to California. The *Palo Verde* sometimes becomes a tree of considerable size; and it is always a most striking and conspicuous object owing to the perfectly smooth, light, bright-green bark which covers its stem and branches. It remains throughout the long, dry and heated season perfectly leafless, but with the midsummer rains puts out tiny leaves, and soon becomes brilliant with a profusion of handsome, bright yellow, pea-like flowers.
C. S. S.

Cultural Department.

Annuals for a Succession of Flowers.

GARDENS should now be bright and gay; every empty spot should have been filled and planting should have been finished. But there will soon come a time when many gaps will occur, and it concerns us now to prepare material with which to fill them. Many annuals are of brief duration. Among these are Nemophila, Collinsias, Virginian Stocks, Clarkia, Lupins, Poppies, Hawkweed and Ten-week Stocks. After a few months many annuals—for instance, Drummond Phlox, Gaillardias, Zinnias, Mignonette, and many more—lose their trim shapes, and it is best to clear them away and recover the ground with fresh plants. When Hollyhocks, Larkspurs, Foxgloves, Canterbury Bells and Sweet Williams have done blooming and are rooted out or cut away, something is needed to occupy the space they filled.

To keep the garden filled, sow at once a fresh set of annuals, and keep them ready to fill up empty spaces as they occur. African Marigolds (the Eldorado strain) are capital for filling into places recently occupied by other plants, and they will keep in bloom till frost destroys them. The cucumber-leaved Sunflower (*Helianthus cucumerifolius*) and *Cosmos bipinnatus* may also be used in the same way. The latter, however, should be grown and starved in pots till its flower buds are set before it is planted out. Raise some fresh dwarf French Marigolds and Petunias to plant in dry ground, as these thrive in such places where many other annuals would perish. Snapdragons in bloom now if cut back would bloom again in the fall, but not in such perfection as young plants raised now from seed. China Asters from seed sown now will bloom in September

and October. Zinnias raised now give fine flowers from August onward. *Coreopsis coronata* and *C. Drummondii* are bright and beautiful yellow-flowered Composites, and should be used liberally for late flowers. About the end of July mildew usually injures spring-sown Drummond Phlox, and good young stock should be provided to replace the old. Put in now a sowing of annual Candytuft and another a month hence. Seeds of *Gaillardia picta*, and its variety *Lorenziana*, sown now will take the place of early spring stock. Corn Flower raised now will bloom freely before the summer is over, so will Balsams, annual Chrysanthemums and Mignonette. The dwarf Nasturtiums are very good in their way, but Lobb's varieties continue in good blooming condition longer than any of the annual sorts. Potato beetles are apt to attack *Nicotiana affinis*, and destroy its beauty before the summer is over. It is well to raise a lot of young plants now, for it is one of the most generous and fragrant of night-blooming plants. In fact, any annual that will bloom within three months from sowing, may be raised from seed sown by mid-June for service in the fall.

dling growth. And if they cannot be set out permanently as soon as they are large enough for transplanting they should be pricked off into other temporary beds, to keep them stocky and cause them to root well and to be in better condition for planting.

W. F.

The Plum and the Curculio.—The plum is generally considered one of the most delicious of the stone fruits, and many persons prefer it to any other product of our orchards. It certainly would be found oftener in home fruit-gardens but for the fact that the curculio has been so destructive. Occasionally, fine fruit is raised in small quantities, with no other precaution than keeping poultry in the yard with the trees. It has long been known, too, that the curculio could be conquered by suddenly jarring the trees every morning, when the insect, inactive and unable to fly, drops into a sheet and is destroyed. This, however, is a tedious process, and a simpler remedy has long been desired. This seems to have been found in the application of arsenical poisons in a spray, by means of a force-pump with a nozzle which throws the poisoned water over the

A Sonora Hillside.—See page 186.

At this time of year it may be well to sow these annuals in a small plot of ground specially reserved for them, in soil which should be moderately moist and very mellow. From this seed bed the seedlings may be transplanted as required. Should warm, dry weather set in, seeds are likely to lie dormant in the ground till after the next soaking rain, but in the case of these succession-crop annuals we cannot afford this inactivity, and they should be kept watered, and, if need be, slightly shaded until after they germinate. In preparing the ground for fine seeds to be sown in summer, in the event of warm, dry weather, it is well to give the ground a thorough soaking with water the day before it is dug, mellowed and sown, rather than to prepare the ground while it is dry, and sow the seeds and water afterwards.

Seeds sown in rows are easier cared for than those sown broadcast, and give a better chance for using a small hoe between them. Seedlings should not be allowed to grow up thickly in the rows, but should be thinned to prevent spin-

tree in a fine mist. The process was described in the first number of this journal, and it only needs to be added that it is not yet too late to save the fruit, as the insect is just beginning to work on the young plums. Of the forms of arsenic used, London Purple seems preferable to Paris Green, being cheaper and less liable to injure the foliage of the tree. It is also in a finer powder, and therefore more easily kept in suspension in the water. Three-fourths of a pound to eighty or one hundred gallons of water is considered a good proportion. The greatest caution should be used with poisons of this kind. The hands of the operator should be protected, and neither horses nor men should be allowed to breathe the vapor. Grazing animals should be kept out of the orchard for some time. If a heavy rainfall, soon after the application, should wash off the poison, a second application may be made. All who have tried this method unite in saying that no danger can come from eating the ripe fruit, as the small amount of poison lodged upon it is dissipated before it matures.

In a paper read before the Illinois State Horticultural Society last winter, Mr. D. B. Wier held that the curculio prefers to deposit its eggs in the fruit of the native plums. He therefore advocates the planting of native varieties among the trees of foreign origin. His claim is that the insects will not only pass by the latter trees for the former, but that a large percentage of the eggs deposited in the native fruit will fail to develop, so that the increase of the pest will be held in check. Another old remedy is dusting the trees with air-slaked lime. It is reported in the bulletin of the Ohio Experiment Station for May, that orchards treated in this way in Michigan have yielded abundant fruit. The lime is applied by means of a flat paddle from a barrel in a wagon which is driven along the rows of trees on the side towards the wind. The lime can also be mixed with water and applied in a spray. This last method has been practiced near Boston with remarkable success. S. A.

Orchid Notes.—*Cattleya Skinnerii alba*, a lovely variety, bearing snow-white flowers with just a few purple stripes in the throat, is a native of Costa Rica, and to be well-grown needs more heat than is usually accorded the type. It delights in abundance of water, both overhead and at the root, during the growing season, and requires a long season of rest, in a cool, dry house. One plant now in bloom here is bearing 25 flowers on two spikes, and they will last a month in perfection, forming the chief attraction of the Cattleya House. *Cattleya Wageneri* is a very rare and chaste var. of *C. Mossiae*, bearing pure white flowers, with a dash of lemon at the base of the large open lip. A superb form is now in bloom with us, the flowers being fully 9 inches across and of good substance. This plant is doing unusually well in a basket filled entirely with sphagnum moss, a capital potting material for most Orchids when care is taken that it does not become saturated with water. A thorough soaking about once a week is often sufficient. *Miltonia (Odontoglossum) vexillaria* will soon be at its best, and may now be seen in abundant varieties. Among the choice of these may be noted var. *rubella*, with flowers of deep rose; var. *leucoglossa*, pale rose, with a large pure white lip; var. *Hilliana*, with large rose-colored flowers, dotted and striped with dark purple; var. *superba*, a deep colored form, the base of the lip being white, with radiating crimson lines. This Orchid is probably the most beautiful of the Miltonias or of the Odontoglossums, to which genus it was formerly referred. Unfortunately it is seldom seen in good condition in this country. In many instances the cause of this is too little water, as may easily be seen by their starved and thrips-eaten condition.

Thrips has always been the pest of this species and will be sure to appear whenever the watering is neglected. The plants should be watered at least once a day and always from overhead. During the hot summer days or when the firing is heavy in winter it may be necessary to syringe the foliage a few times. Under this treatment thrip never attack the plants here. In respect to heat we try to keep a temperature of 60°–65° the whole year round. We use peat and moss in equal parts for potting, particular attention being paid to drainage. Under the above treatment these Orchids grow like weeds, producing 3 to 4 spikes of flowers from a bulb and increasing the number of leads and size of bulbs every year.

Kenwood, N. Y.

F. Goldring.

Staking Plants.—Hollyhocks, Dahlias, perennial Larkspurs, Bottonias, Sunflowers and many other tall-growing, top-heavy plants, will need staking. Never wait till the plants grow large and are blown over or broken down, but stake them before they need support. Once the stakes are set, it is an easy matter to tie up the plants occasionally, and in this way to preserve their good form. Use neat stakes, but strong ones, and firmly set. A large Dahlia, heavy with rain, will require a strong support in a high wind. Chestnut, locust and red cedar stakes worked at the saw-mill in suitable lengths, and from one to two inches square, and with the sharp corners planed off, can be used for tall, heavy plants like Dahlias and Sunflowers and for young trees. Good stakes can also be made from the refuse yellow pine which can be procured at many saw-mills. Such heavy and stiff stakes are not best for tall Lilies like *L. auratum*, *L. superbum* and others, which grow from five to nine feet high, but long, strong, elastic stakes are preferable. These sway a little in the wind with the plant, and at the same time are perfectly secure, and for this purpose there is nothing better than Red or White Cedar saplings such as are used for bean-poles, slender and neatly dressed. Almost any stake does for smaller plants, although the cane stakes so much used by florists are not of much value in the flower garden; they rot off in the ground too quickly. But whatever

is used should be neat, and firmly set, and, if the plants are in rows, accurately in line. The plants should grow higher than the stakes, and they should be so tied as to hide them, and at the same time not to appear as if crushed or in an unnatural position. W. F.

The Rock-Garden in Spring.

TULIPS are still conspicuous among the plants flowering this week in the New England rock-garden. The most beautiful of them is the Lady Tulip of gardens, *Tulipa Clusiana* (also known as *T. praecox* and *T. rubro-alba*), a common plant from Portugal to Persia, and one of the most clearly marked and least variable of all the Tulips. It has linear, acuminate, channeled, glaucous leaves, a slender flexuous stem, twelve or eighteen inches high, and a delicate white flower two inches long, the narrow segments marked on the inside with a handsome purple spot, the three outer flushed externally, except along the edges, with bright red. The anthers and filaments are dark purple or nearly black. The flowers of *Tulipa acuminata*, or, as it is often known in gardens, *T. cornuta*, are always striking and interesting. They are sometimes scarlet and sometimes yellow, and these colors are sometimes blended. The segments are very long, and all are narrowed gradually into a long, narrow, horn-like point. This is a very old inhabitant of gardens, and a very distinct type, but its native country is not known. It is very hardy here, and one of the most easily cultivated of all the Tulips. *Tulipa reflexa* is also in bloom. This is another Tulip which is only known in gardens, and which, as Mr. Baker has suggested, is probably a hybrid between *T. acuminata* and *T. Gesneriana*. It has handsome bright yellow flowers, two and a half to three inches long, the segments narrowed gradually to an acute point and sharply reflexed above the middle when the flower is fully expanded. Among our native Violets worthy of a place in the garden is *Viola pubescens*, the common yellow Violet of northern woods, with broadly heart-shaped, downy leaves, and rather small bright yellow flowers, which continue to appear during several weeks. It takes kindly to cultivation, thriving in the shade, and is springing up everywhere in the rockery from self-sown seed. The Pepper-root (*Dentaria diphylla*), another inhabitant of northern woods, probably is not seen very often in gardens, where, however, it can well fill some shady nook or pocket in the rockery. It has large compound leaves, with three rhombic-ovate, coarsely cut leaflets and short racemes of rather large white flowers. The long, fleshy, toothed root-stock peculiar to the plants of this genus of the Mustard Family (*Cruciferae*) have a pleasant pungent flavor, to which they owe their common English name. Another pretty shade-loving native plant now in flower is *Waldsteinia fragoides*, a low perennial herb, with leaves divided into three cut-toothed lobes, and small bright yellow flowers, in size and shape not unlike those of the Strawberry, but produced upon many-flowered scapes rising above the foliage.

Gardeners hardly realize or appreciate the beauty of our North American Lady Slippers (*Cypripedium*), and yet among them are plants as showy and far more delicate and beautiful than any of the tropical species in which the horticultural world is just now so deeply interested. All the species of the Eastern States are perfectly hardy and can be grown as easily as any of the more delicate of our wild plants. They will thrive, with the exception of *C. acaule*, which requires drier soil and a more sunny exposure, along the margins of Rhododendron beds in peaty loam, or in the shady and least dry parts of the rock-garden. They are easily transplanted and make excellent pot-plants, if needed for the decoration of conservatories or living-rooms. The only one of these interesting plants blooming here now is the larger of the two yellow flowered species, *C. pubescens*. It has stems two feet high, pubescent like the broadly-oval, acute leaves, and handsome flowers, with a pale yellow gibbous lip, and long, linear, twisted petals. It is the common bog species north and west, and is found also on the Alleghany Mountains.

Varieties of *Iris pumila*, with bright-blue and with yellow flowers, are now in bloom. It is a dwarf European species, three or four inches high, with large solitary flowers, well suited to the rock-garden, and an excellent subject for a dwarf edging to the herbaceous border. The dwarf Iris is very hardy, and spreads rapidly, soon making broad, dense mats. Not less beautiful is the crested dwarf Iris of the southern Alleghany Mountains (*Iris cristata*), a low plant, with leaves only three or four inches long, and very handsome, light blue flowers, with a long, slender tube much longer than the short-clawed divisions of the perianth, of which those of the outer series are

beautifully crested. This is a hardy plant, spreading rapidly by creeping root-stocks, and admirably suited for the border of wood-walks and other rough parts of a garden, where it can more than hold its own against weeds and grasses.

Arnebia echinoides is one of the most showy of the hardy perennials now in flower. It is a native of Armenia and a member of the Borage Family, nearly allied to *Lithospermum*. The stems, which grow from six to twelve inches high, are terminated by large, one-sided, solitary spikes of handsome, primrose-colored flowers, marked at first with purple spots in the sinuses between the lobes of the corolla, but which entirely disappear at the end of a few days. The sessile, alternate leaves are ciliated on the margins like the stems. *Arnebia echinoides* may be increased from cuttings made from the stems and from the roots, and it is easily raised from seed.

Aubretia deltoides is one of the prettiest of hardy, spring-blooming rock-plants. It is an evergreen trailer, with terminal few-flowered racemes and small rhomboidal leaves, which just now is covered with sheets of handsome, pale purple, four-petaled flowers, half an inch across. It requires deep soil and rather an open exposure, where it can spread through the crevices between the rocks and send its trailing stems over their surface. It can be easily increased by cuttings and from seed, which, if sown as soon as ripe, will make strong flowering plants by autumn.

Scilla Hispanica, or, as it is generally known in gardens, *Scilla campanulata*, is the latest of the genus here in flower, blooming with the Poet's Narcissus, the two being excellent plants to associate together in beds or wild wood-borders. The flowers are deep blue, bell-shaped, half an inch deep, racemose, and spreading nearly at right angles from the slender six to twelve flowered scape, which is eight to twelve inches high, and springs from a rosette of linear strap-shaped leaves. There are varieties with white and with flesh-colored flowers. It thrives in dry and in comparatively wet soil; and it is one of the best of the hardy bulbs which can be naturalized here in grass along the borders of woods and wood-walks.

Ornithogalum nutans, the Satin Flower of some old New England gardens, is such an old-fashioned flower that few people nowadays know it. And yet it is a beautiful and a very hardy plant, which has been growing in this garden for over forty years; and during all these years its modest flowers have given fresh and ever increasing delight. It is a bulbous plant of the Lily family, a native of southern and central Europe, with four or six strap-shaped, flaccid leaves, and a loose raceme of five or six large, nodding, bell-shaped flowers. They are an inch long, with broad, petaloid filaments; the segments of the perianth are white, broadly flushed with pale green on the outside, smooth and shining like satin, and less spreading than in other species of this genus. The Satin Flower flourishes in all soils, in the full exposure to the sun and under the dense shade of overhanging trees and bushes.

Among Pæonies the earliest in bloom is one of the single-flowered forms of *P. tenuifolia*, with rather broader leaf segments than are found in the typical plant. The single-flowered variety of this handsome south Russian plant is much less often seen in gardens than that with double flowers, although it is certainly far handsomer and more attractive; and this is true of all Pæonies, whether herbaceous or shrubby, that the single are handsomer than the double flowers, although double-flowered varieties are almost invariably grown in American gardens. *P. tenuifolia* produces solitary, dark crimson, cup-shaped flowers, surrounded by the crowded, reduced upper leaves, terminal upon stems twelve to eighteen inches high; the leaves, of which there are ten or twelve upon each plant, are cut into narrow, one-nerved, confluent segments, which vary in width from one-twelfth to one-fourth of an inch in different varieties. *P. tenuifolia* is a perfectly hardy plant of the very easiest cultivation.

Boston, May 25th.

C.

Notes from the Arnold Arboretum.

THE number of plants in flower in the Arboretum this week is not large. Among the Barberries, one of the earliest in bloom is the form of *Berberis vulgaris* from northern China and Manchuria—the var. *Amurensis*, or *Berberis Amurensis* of some authors. Of the many forms of the common Barberry now cultivated this is one of the most distinct, interesting and valuable from a garden point of view. The leaves are much larger than those of the common Barberry and the stems are stouter and more rigid, although the Chinese plant will not attain probably its height and dimensions. Indeed, Maximowicz, in his "*Flora Amurensis*," describes it

as a low shrub, rarely more than three feet high, a stature which the Arboretum plants have already surpassed. The flowers are somewhat larger than those of the common Barberry, possessing their delicious fragrance, and appear here fully two weeks earlier. This is one of the most desirable of the perfectly hardy deciduous shrubs of comparatively recent introduction. It is a free-growing plant which can be readily increased by cuttings or division, or from seed, which has not been produced yet on the plants in this collection.

Every lover of nature in America, and nearly every gardener, knows the Great Laurel, or, as the people who inhabit the southern Alleghany Mountains, where it grows with a perfection and beauty unknown elsewhere, call it, the "Ivy," but the little northern Swamp Laurel, *Kalmia glauca*, is less known. It is, nevertheless, when in flower one of the handsomest of the small shrubs of North America, where it is found from the Pennsylvania Mountains far northward, always in cold peat-bogs. *Kalmia glauca* rarely exceeds a foot in height; it has a loose straggling habit, narrow sessile, oblong, revolute leaves, white glaucous on the lower side, and terminal, few-flowered, smooth corymbs of large and very showy lilac-purple flowers. It is not an easy plant to establish in cultivation, although when once established and left to grow without any effort being made to improve its habit by pruning (which seems fatal to it) it will flower freely year after year. Great care is needed in taking up young plants for cultivation, which should be thoroughly rooted in pots or boxes before they are planted in the garden. *Kalmia glauca* is now well established in the Arboretum, where it has flowered for several years.

Much more easily cultivated is the beautiful Rhodora, which botanists now refer to the genus *Rhododendron*, as *R. Rhodora*. The Rhodora which is one of the best known and best loved wild flowers of New England, can be easily transferred to the garden from the cold northern swamps, which at this season of the year are tinged with its handsome rosy flowers. It is a low deciduous shrub, two or three feet high, with oblong leaves, downy on the lower side, and appearing later than the umbel-like terminal clusters of flowers. It requires a deep peaty soil, in which it will soon spread, and make large clumps.

Fothergilla alnifolia is too rarely seen in gardens. It is a low and very hardy shrub belonging to the Witch-hazel family, with showy terminal, catkin-like spikes of small flowers, with numerous long, projecting white stamens. They are the only conspicuous part of the flower. It has no petals and a small bell-shaped calyx. The oval or obovate leaves, smooth, or pubescent on the lower side, appear later than the flowers. The Fothergilla, although not found growing naturally anywhere north of Virginia, is perfectly hardy here.

Clematis (Atragene) verticillaris, a rare plant confined to the mountainous or far northern part of the country from northern and western New England and Virginia to Wisconsin, is the earliest of the genus in flower here. It is a woody climber with stems six or eight feet long, trifoliate leaves, and large, handsome blue or purple spreading flowers, two or three inches across, which in the mountains appear sometimes with the melting snows. This plant requires ordinary garden soil, and no special cultivation.

The earliest of the brambles in flower is also an American plant—*Rubus triflorus*, the dwarf wild Raspberry of northern swamps and woods, with annual herbaceous stems six to twelve inches high, handsome ovate-lanceolate, doubly-serrate leaves, pointed at both ends, and one to three flowered clusters of white flowers followed by small inedible fruit. It is an exceedingly pretty little species, which, when established, makes a neat compact mass of foliage, well worth a place on the borders of the shrubbery.

Ribes multiflorum is a Hungarian species rarely seen in gardens. It is a handsome shrub at this season of the year, with numerous upright and spreading branches three or four feet high, long-petioled, three or four lobed leaves, which are dark green and glabrous above, lighter green and very pubescent on the lower side; and long, dense, pendulous racemes of green flowers. The fruit is red and about the size of a pea. The plant, although more interesting than showy, might well be cultivated more frequently. A beautiful figure of it (*t. 31*) will be found in Lavallée's "*Icones*."

Ribes Uva-crispa is a smooth-fruited plant which botanists consider one of the wild forms of the common Gooseberry. It is a low shrub with rigid branches two or three feet high, densely armed with stiff yellow prickles, small, orbicular, palmately divided leaves, hairy on both sides, and with green flowers, hanging singly or in pairs from little tufts of green leaves. The berry is small and yellowish. It is found in hedges and open woods of central and southern Europe and

western Asia, and has been cultivated for centuries for its fruit. A plant of the America Red Currant (*Ribes rubrum*) is a beautiful object in flower. It is not considered distinct from the garden Currant of Europe, although the veins of the leaves are white beneath, which led Michaux to apply to the American plant the name *albinervum*, and the yellow-green flowers are larger and more conspicuous than those of the European Currant. The stems are straggling or reclined and three to five feet long. The wild Red Currant is an inhabitant of cold bogs and woods from northern New Hampshire and far northward. *Ribes floridum*, the wild Black Currant of our northern woods, is in bloom also, and resembles the Black Currant of gardens. It is a shrub three to five feet high, with heart-shaped, lobed, resinously dotted leaves, drooping racemes of large and handsome greenish or white flowers, and black berries with the smell and flavor of those of the garden plant. These two wild American Currants probably will not be often found in those gardens where plants of merely botanical interest are not cultivated.

The Corchorus (*Kerria Japonica*), with its bright yellow and very double flowers, is almost invariably found in old country gardens in the Northern States, but this plant in its natural state with single flowers, each with five petals and numerous stamens, is still rare. It is, however, a far handsomer and more desirable plant. The *Kerria* is a shrub five or six feet high, with slender, virgate, flexuous stems, and ovate-lanceolate, longly acuminate, doubly serrate, deciduous leaves, rounded or subcordate at the base, and solitary flowers terminal on short lateral branches (in the single form wide spreading, an inch and a half across) and appearing with the leaves. The fruit has probably never been produced in this country, and according to Von Siebold it rarely ripens in Japan, where the plant is everywhere cultivated, and now widely distributed in a semi-wild state. It is found in the mountainous regions of central China, and like the Ginkgo and several other plants, for many years known to Europeans from Japan only, it is probably a native of that country. In central China the fruit is reported to be "yellow and good to eat like a Raspberry," the Chinese name indicating that it produces an edible berry. The single and the double flowered forms are beautifully figured in Siebold and Zuccarini's "*Flora Japonica*," t. 98.

Daphne Genkwa is another Chinese plant long cultivated in Japan, and first made known by Von Siebold, who found it in Japanese gardens and described and figured it in the "*Flora Japonica*," t. 75. The *Genkwa* is a handsome and interesting shrub with spreading tortuous branches covered at this season of the year with sessile lateral fascicles of two to seven handsome, tubular, lilac-blue, precocious flowers about an inch long, the tube, like the ovary, densely coated on the outside with silky hairs and quite smooth within. The leaves, which appear sometimes later than the flowers, are opposite, membranaceous, short petioled, about an inch long and quite entire. The *Genkwa* is very generally cultivated in Japan, both on account of the beauty of its flowers as an ornamental plant, and for the flowers and bark, which are believed to possess valuable medicinal properties and are frequently used and highly esteemed by the Japanese. *Daphne Genkwa* is not very hardy here, and like nearly all the other species of the genus in the collection, requires in winter a slight protection of evergreen branches.

Daphne Cneorum, a trailing evergreen shrub of central and southern Europe, with tough, wiry stems, smooth, lanceolate, glabrous leaves, and terminal clusters of bright pink, deliciously fragrant flowers, is now in bloom. It is a free blooming plant, but not very hardy nor satisfactory in this climate. Sometimes it grows well for a number of years, forming wide, handsome mats, and then, in a winter apparently not more severe than those which have preceded, it dies, or is seriously injured. In some exposures and situations it appears to do best when unprotected in winter, in others a covering of evergreen branches appears beneficial. It is well worth all the care and attention necessary to secure its free growth and abundant flowers.

Two *Spiræas* in addition to the two mentioned in the last issue of these notes are now in bloom, *Spiræa media* and *S. hypericifolia*. The former is a tall, erect shrub with round branches, flowering after the leaves have attained their full size. They are elliptical, acute and obtuse, entire or sometimes deeply serrate at the end, three or four ribbed, smooth above, hairy on the lower side and on the margins. The handsome, many flowered corymbs terminal on lateral, leafy branches of the year are produced in great profusion, for a distance of two or more feet along the ends of the main branches. *Spiræa media*, which is often confounded in gardens with *S. chemadryfolia*, which has square branches and smaller and more generally serrate leaves, is one of the best of the

early flowering *Spiræas* here, of its section. It is very hardy, grows rapidly in all soils and it can be transplanted with the greatest ease. It is found in Hungary and southern Russia, and through Siberia to Kamschatka and Mongolia. *Spiræa hypericifolia*, known sometimes in gardens as Italian May, or St. Peter's Wreath, is a tall shrub with long, slender, flexuous, round branches, small, wedge-oblong leaves, entire or slightly crenate or lobed at the end, and small white or cream-colored flowers in nearly sessile lateral umbels, terminal on very short leafy branches. A variable species, of which several forms are distinguished, it is found from western Europe through Siberia to Mongolia.

May 25th.

The Forest.

Forest Trees for California.

IN the second number of GARDEN AND FOREST I mentioned the "English" Oak (*Q. Robur pedunculata*) as a promising timber tree for California. The facts thus far gathered concerning this rather unexpected adaptation are these: The acorns of this Oak (from a tree in New England) were first planted on the experimental grounds of the University in 1879, with a number of species of eastern Oaks, which were increased in succeeding years. All of these, however, were found to be of exceedingly slow growth, showing little or no inclination to utilize the long growing season of California. After two years' growth none of the American Oaks had attained a greater height than eighteen inches, the average being from eight to ten only. Of the European Oak seedlings, none measured less than twenty inches, and a number were three feet in height, with strong branches. Attention having thus been called to the possible importance of this tree for California, several importations of acorns were made subsequently, and these, with seedlings a year old, were distributed for trial to numerous localities in the State.

Unfortunately, but few of these seem to have found favorable conditions for their prosperity, from causes sufficiently apparent from the experience had upon the University grounds themselves. It was found, first, that the acorns were extremely attractive to all sorts of depredators, including blue jays, rats, gophers (*Thomomys umbrinus*) and ground squirrels (*Spermophilus fossor*), and that, therefore, but a small percentage of the acorns sent out ever germinated. Those that did germinate, however, were reported to be growing thriftily and rapidly. How long they continued to do so, will have depended largely upon the protection afforded them from cattle, which seem to be as fond of the foliage as the other animals mentioned are of the acorns; moreover, the ground squirrel and gopher delight in gnawing the roots and trunks as well. But few of the trees escaped mutilation from one or the other cause, and even the one which is the best representative of the stock grown by the University experiment station, now beginning its seventh year, lost fully one season's growth, being weakened by removal and having been bitten off by a horse. It thus shows properly the result of five years' growth only. It is now sixteen feet high, with a trunk six inches in diameter a foot from the ground, and separating at three feet into three branches, forms a spreading top, fourteen feet across. The tree has now set an abundant crop of acorns, and a seat is made around it, the occupants of which will be fully shaded during the warm hours of the day.

A Black Oak (*Q. tinctoria*) of the same age and grown without any interruption, is a bush scarcely six feet high and having as yet no aspirations to become a tree. Its growth is about the best among the eastern Oaks.

Two species of Hickory (*Carya porcina* and *C. tomentosa*), also contemporaries, have as yet hardly risen above four feet, and, like many eastern trees, show their aversion to the climate by sending up suckers from the base as soon as the shoots of the previous year have made a growth of a few feet.

This enormous difference in favor of the European Oak seems partly, at least, due to its peculiar root habit. A seedling a year old, appearing above ground with a stem the size of a goose quill at the base and six to eight inches high, will show a straight tap root three to four feet long and one-third of an inch thick near the crown. It thus quickly reaches a depth in the soil where moisture is found during the whole of the rainless summers of California; and hence, doubtless, its vigorous growth during the entire long growing-season, the leaves remaining active from after March to the end of October. The latest leaves, however, belong almost entirely to the second growth, which pushes out very vigorously toward the end of June, and frequently reaches a length of four feet before the end of the season.

But all this is very much changed when the tap root has been seriously shortened, or destroyed in transplanting. The European Oak then assumes the habit of root, as well as of stem, exhibited here by the eastern Oaks, and its growth becomes equally slow. Some two-years-old seedlings, transplanted from the nursery to the brow of a dry hill above the University, show this to perfection. The tap roots having, of necessity, been badly mutilated, fibrous roots branch out from the stump, but have thus far, in two years, been unable to reach the moist depths of the very rich soil. They have not only no second growth, but no tendency even to form a definite trunk; the branches tend to spread out low, and between them, crops of suckers rise from the base of the stem at the time when the standard trees begin their second branch growth. These weakly shoots form the next year's branches, while the larger ones frequently die back. This curious habit, resulting in the formation of low, scraggly bushes, instead of stately trees, is just what is shown here by the Oaks of the Mississippi Valley when left to themselves; and the unlooked for resistance of the European Oak to the severe drought of the California summer, as well as its surprisingly rapid development, thus seems to find a simple explanation in the peculiar habit of its root to push down into the moist soil the very first season. It would be interesting to know whether in its native country, or in the region of summer rains in the United States, it exhibits a similar tendency.

Thus, while this Oak promises excellent results as a timber tree, not only for California, but, doubtless, *à fortiori*, for Oregon, its propagation evidently requires considerable care. The acorns must either be planted where the trees are to stand, or transplanting must be done while the seedlings are quite young, and with great care not to mutilate the tap root. Both acorns and seedlings must be fully protected against animal depredations, especially against the rodent family, and later, as saplings, against ranging cattle and horses.

But if, as may reasonably be hoped, these precautions will insure to the Pacific coast a supply of hard-wood timber that will do away with the heavy cost now involved in the importation of this necessary material, the labor will be amply repaid. It may be objected that with such rapid growth, the timber may not possess the same qualities as in its native climate. But when it is considered that the more rapid growth is accomplished in a proportionately longer space of growing time, this apprehension loses much of its force; and it is not at all probable that the English Oak, with a habit so widely different from that of the native Oaks of California, should produce a wood of a quality so inferior as theirs.

University of California, May, 1888.

E. W. Hilgard.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—Is there not some way of inducing the guardians of the Central Park to remove the hundreds—indeed thousands—of dying Norway Spruces which so seriously deface its beauty? There is scarcely a point of view in the whole park from which

some of these trees may not be seen in a very advanced stage of hopeless decay and ugliness. Just at this season, when everything else is clothing itself with fresh green, their mournful, miserable forms are especially distressing; but there is no season when they are not eyesores in themselves and witnesses to want of attention or want of judgment on the part of the Park authorities. Of course the cutting of trees which are sickly beyond hope of recuperation sometimes involves the necessity of replanting, but with regard to most of these Spruces this would not be the case. Let any one follow the East Drive, for example, and note those which are the most obtrusive in their decay. He will find, if he has any eye for the grouping of trees and the effect of landscape arrangements, that in a great majority of cases their presence would be undesirable even if their condition were better. Nature seems by chance to have recognized this fact, for in one or two places in the park where the presence of Spruces is really desirable, they have flourished well. On the West Drive, for example, near the well-known group of Weeping Beeches, stand several Norways in fine condition, and admirably placed as regards the general effect of the scene.

I know, of course, that difficulties attend the cutting of trees in public places. Fetish-worship, as directed to trees, seems not yet to have become extinct in the minds of the ignorant; and whenever an axe is laid to a trunk in the Park there is almost sure to be a letter in some daily paper from some cranky loungee calling attention to the reckless injury to public property which is being worked. By such persons a park seems to be regarded simply as an expanse of ground in which to grow trees—not an expanse in which they should be grown in the right places and grown well. But the Norway Spruces of the Central Park are now so far advanced in decay that even the self-appointed apostle of ignorance in tree-preservation could hardly raise his voice in their favor. And whether he should protest or not, intelligent public opinion would certainly sustain the Park authorities should they enter upon a campaign of almost wholesale cutting. It would be a relief to intelligent eyes to be rid of these distressing objects, and an even greater relief to note the increased chance for development which their removal would afford to their healthy neighbors, and the increased beauty of the wayside groups or little dells which they are now crowding and deforming.

New York, May 1st.

Philodendron.

To the Editor of GARDEN AND FOREST:

Sir.—In regard to the hardiness of the Spanish Chestnut, of which you ask the experience of your readers, I would say that it is somewhat tender here, but hardly more so than the English Walnut. Both are tender when young, losing the extreme ends of their branches in winter. As they get stronger year by year, this loss does not occur, and, in time, they become large, fruitful trees. Of both the Spanish Chestnut and the English Walnut there are many very large trees about Philadelphia, bearing fruit freely every season.

Germantown.

Joseph Meehan.

Recent Publications.

The Botanical Works of the late George Engelmann. Collected for Henry Shaw, Esq., and edited by William Trelease and Asa Gray. Pp. 548. Cambridge, 1887.

Mr. Henry Shaw, of St. Louis, the founder of the Botanical Garden of that city, which bears his name, has certainly reared a more appropriate memorial to his old friend and fellow-townsmen, in causing this volume to be made, than any statue of bronze or of marble could have been.

Dr. Engelmann's botanical writings cover a period of about fifty years; they relate chiefly to the plants of North America, generally to the most difficult families and genera, for which Dr. Engelmann had a special predilection; and often to plants of the highest horticultural importance and interest, such as the Oaks, Pines, Firs, Grapes, Agaves, Cactuses and Yuccas. In these and in other families he was long the leading authority, and his writings must always be referred to. They were widely scattered through government reports, the proceedings of learned societies, and the columns of periodicals, and quite inaccessible to the general student, who will now welcome this handsome and substantial addition to botanical literature. The different papers are grouped by subjects under fourteen chapters.

No. 1. Contains Engelmann's inaugural thesis *De Antholysi Prodrumus*, a remarkable morphological paper which attracted the attention and won the approval of Goethe.

No. 2. Contains the sketch of the Botany of Dr. A. Wislizenus's expedition into northern Mexico.

No. 3. The various papers on the Dodders (*Cuscutineæ*), a family which Engelmann studied for many years, and finally elaborated in a classical memoir.

No. 4. Contains all the papers, fourteen in number, on the *Cactaceæ*. These embrace, perhaps, Engelmann's most important botanical work. Many of these were first published by the United States Government, and were beautifully and elaborately illustrated. These and the other illustrations, joined to Engelmann's previous publications, all appear in this reprint and add greatly to its value.

No. 5. Contains the papers on *Juncus*.

No. 6. Contains all the papers on *Yucca*, *Agave* and similar plants, which, like the Cactuses, botanists are generally willing to pass by, because they are so difficult to manage in herbaria, but which Engelmann loved and studied through years of patient and painstaking research.

No. 7. Contains all the papers on Conifers, which no one knew so well or studied so faithfully.

No. 8. Contains the papers on Oaks, and the best information which yet exists in regard to the botanical characters and relationship of the North American species of these most difficult plants.

Nos. 9, 10 and 11. Contain all that Engelmann wrote about the American Grape Vines, on the *Euphorbiaceæ* and on *Isoëtis*. In No. 12 are collected the shorter miscellaneous papers; in No. 13 are various lists and collected descriptions of plants, and in No. 14 are several general notes upon features of vegetation in different parts of the United States.

The editors of this volume have wisely abstained from making any changes in the text as the author left it or from adding explanatory notes, when recent investigations might naturally have led him to change his views. Their task, however, has not been a light one, as many of the papers were published under conditions unfavorable for proof-reading, and others were never revised by the author. An excellent portrait of Dr. Engelmann, from a photograph taken during the last ten years of his life, increases the value and adds to the interest of this memorial.

Professor Trelease is prepared to furnish a few copies of this book in sheets, which will be delivered to the Express Companies at St. Louis, at cost price, twelve dollars.

Notes.

The California Florist is the title of a new illustrated monthly published at Santa Barbara and San Francisco and devoted to the interests of floriculture on the Pacific Coast. Judging from the first number the new enterprise seems to be in capable and energetic hands, and deserves success.

At an auction sale of a lot of imported Orchids recently held in Boston, a healthy plant of *Cypripedium Fairrieanum* with two new breaks brought \$240. At the same sale a plant of the well known hybrid, *Cattleya Exoniensis*, raised many years ago by crossing *C. Mossiæ* and *Lælia purpurata*, was sold for \$105. Other plants brought prices proportionally high.

In a paper from the Botanical Institute of the University of Pavia, Dr. Fridiano Cavara describes a number of new fungi which infest grape-vines in Italy, and, in referring to American species, he expresses the opinion that the *Greeneria fuliginæa* of Messrs. Scribner and Viala, which was considered by them the type of a new genus, is in reality a form of *Coniathyrium Diplodiella*, and he states that the same form was previously known in Italy.

Small flat Peaches, grown in Florida, have been on sale in our markets for several days, under the name of "Japanese Peaches." It is the fruit of the "Flat Peach of China," which Decaisne believed to be a species (*Prunus platycarpa*), but which later botanists now consider merely one of the many forms of the common Peach cultivated by the Chinese. The Flat Peach is a large and vigorous tree, with long, slender branches, nearly evergreen foliage, pale pink flowers and small fruit, two and a half to three inches wide, so flattened on the upper and lower sides that it is rarely more than one inch deep, with a deep five-angled eye at the top. The stone is round, two-thirds of an inch in diameter, flattened like the fruit, and slightly wrinkled. The flesh, which adheres slightly to the stone, is juicy and of excellent flavor, although the skin is thick and rather tough. The flower-buds of this tree are generally killed at the north, but it is evident from the earliness and excellence of the fruit in this market, that its more general cultivation in the south may be made profitable.

The auction sales of plants in this city show no decline in activity as the spring season closes. They are held every

Tuesday and Friday, and on more than one occasion as many as 50,000 plants have been disposed of. The stock in the main is small though well-grown, and was formerly bought by the trade, but lately, and especially this year, many private buyers resort to the warerooms of Young & Eliot for bedding plants and the like. The prices this year have hardly exceeded two-thirds of the wholesale trade prices—but growers do not complain, because when plants are sold in large lots at a cent each, buyers take an increased supply. The sales are not confined, however, to cheap stock. Fine specimen plants are often sent here. At one auction not long ago, where many well-grown Palms were sold, a good specimen of *Phoenix rupicola* brought \$94, and experts pronounced it worth \$150. The total amount received at that particular sale was between \$4,000 and \$5,000.

Retail Flower Markets.

NEW YORK, June 8th.

Cut flowers are inferior in quality, as a rule, and there is less variety in the shops. Mignonette remains of good size. Peonies are large, and well grown, and sell for from 16 to 20 cts. each. La France Roses are very fair and cost \$2.50 a dozen. Catherine Mermets and Brides are not large but are otherwise excellent; they bring \$2 a dozen. Niphetos and Perles des Jardins cost \$1.50 a dozen. General Jacqueminots are unsatisfactory, although stems are longer than a week since. American Beauties and Paul Neyrons are the finest. All selected Hybrids sell for \$5 a dozen, or 50 cts. each. Puritans cost 40 cts. Moss Rosebuds are unusually pretty and mossy, bringing \$4 a dozen. Yellow Daisies are 40 cts., and white Marguerites, which are really field Daisies, bring from 15 to 25 cts. a dozen. The blue Cornflowers are highly esteemed and always in demand; they cost 15 cts. a bunch of from 15 to 25. Water Lilies from New Jersey ponds are in market at 25 cts. a bunch of 3. Carnations are much improved in quality and command 50 cts. a dozen. Snowballs are in brisk demand. Cattleyas bring from 50 cts. to \$1 a flower. Many bedding-plants are seen in florists' stores. These are well cultivated and make a brilliant blaze in windows, doorways and on plant-stands. Business has been brisk among florists generally this week with orders for out-of-town entertainments and for city weddings.

PHILADELPHIA, June 8th.

The quality of flowers, especially Roses, has fallen off decidedly this week. The notable exceptions are Meteor and Madame Cuisin, both of which can be relied upon to give good flowers during the hot summer months. A few Roses are being cut out-of-doors from sheltered positions in favored localities near the city. The Jacqueminots from under glass are by no means good. They sell at from \$1.50 to \$2 a dozen, the same as Mermets and La France, while The Bride, Perle and Sunset are from \$1 to \$1.50. Bennett and Gontier are steady at \$1.50. Niphetos, \$1. Bon Silene and Safrano, 75 cts. Hybrids, \$3. American Beauty averages better in quality than the Hybrid Remontants in general, and brings from \$3 to \$4 a dozen. Carnations, Heliotrope and Mignonette are 25 cts. per dozen. Lily-of-the-Valley, \$1. Pansies, 10 cts. Smilax from 40 to 50 cts. a string. *Asparagus tenuissimus* from 50 to 75 cts. a string. *Adiantum cuneatum*, 25 cts. per dozen fronds. Sweet Peas, 50 to 75 cts. a dozen. Cornflowers, blue, white, pink and purple, are 25 cts. a dozen, while the yellow Cornflower is 35 cts. a dozen. Field Daisies are 25 cts., and Dahlias, double and single, \$1 to \$1.50 a dozen. The Miniature Sunflower (*Helianthus cucumrifolius*) is offered in limited quantities at 50 cts. a dozen. This is a beautiful and useful annual.

BOSTON, June 8th.

There is an abundance of flowers here now; in fact, an overstock, particularly of Roses. Prices are low, and the street corners are well supplied with peddlers, who dispose of an enormous quantity of flowers at seasons when the supply is heavy. These dealers are not in favor with the store florists, who have often tried, but as yet without success, to have these street sales prohibited. Whether they injure the store trade or not, they certainly dispose of many flowers to people who would not otherwise buy, and they render a valuable service to the growers by using up their second quality and surplus stock. Those customers who want the best, properly packed, and delivered at their homes, must always go to the regular stores, and, everything considered, these probably get their flowers cheapest in the long run. The main stock of Roses coming in now consists of Teas and the commoner fancy Roses. With the exception of American Beauty and Jacqueminot, there are few large Roses. Jacqueminots are not as good as they have been. The hot weather brings small and thin blooms. Out-door Roses do not show color as yet. Long-stemmed Carnations are quite plenty, and so are Stocks, Heliotrope and Mignonette. Good Lily-of-the-Valley is very scarce, and brings winter prices. Other bulbous flowers are out of market entirely. A good many Ghent and "Mollis" Azaleas are brought in now, and are very useful and effective in large decorations. Prices by the dozen range as follows: Tea Roses, 50 cts.; Mermets, Perles, Sunsets, Niphetos and Brides, \$1 to \$2, according to quality; Jacqueminots, \$3, and American Beauties, \$4; Lilies-of-the-Valley, \$1; Heliotrope and Mignonette, 50 cts. Smilax, 50 cts. a string. Maidenhair Ferns, 50 cts. a dozen. The florists are all very busy, and appear to have a satisfactory spring trade.

The Association of American Nurserymen.

THE nurserymen of the world have played such an important part in the general advancement of horticulture, that all planters and lovers of plants have something akin to a personal interest in their prosperity. That our parks and gardens have been enriched with such a variety of beautiful plants from all quarters of the globe is largely due not only to the business enterprise of nurserymen, but also to their intelligence and skill, and, we may add, to their enthusiastic, self-denying and too often unappreciated devotion to the cause of horticulture. We are sometimes inclined to criticise the glowing descriptions and highly colored pictures of novelties in the trade catalogues, but, on the other hand, these same catalogues must take rank among the most effective means of disseminating information of practical value concerning trees and shrubs and fruits and flowers. It is to the trial grounds of the great nurseries, more than to any other place, that planters have been obliged to turn for object lessons in cultivation and for instruction as to the hardiness, the beauty and the distinctive characteristics of trees and plants for the forest, the orchard and the garden. This means not only that nurserymen must be depended on for the material used in landscape gardening, forestry and fruit growing, but that a good share of our knowledge of these subjects has been derived from their studies and labors.

All persons, therefore, who take any interest in gardens or forests cannot but hope that the annual meeting of the Nurserymen's Association, to be held this week at Detroit, will prove successful in point of attendance and in the value of its deliberations. A large proportion of the subjects considered will be distinctively of a business character, but even these may benefit every tree-buyer. It was concerted action at a former meeting which effected the just reduction of freight rates for nursery stock, which is a direct advantage to every planter. Much remains to be done towards insuring such stock in transport against disastrous delays and exposure and towards holding railroad and express companies responsible for safe and speedy delivery, and this subject will, no doubt,

command the attention of the meeting. But perhaps the greatest benefit derived from these gatherings is found in the interchange of personal experience among the members. Very often papers of real and permanent value are read and published in the reports of the association. But the discussions which follow the reading of these papers are generally of more importance still, having a freshness of suggestion and a directness of aim which are never so manifest elsewhere as in the flashes which come from the contact of alert minds in friendly argument. Fortunately, there are no secrets in American nursery practice and no attempt at concealment interferes with the mutual improvement which comes from this reciprocity of ideas, and in this way the garnered experience of individuals in every part of the country becomes the common property of all.

Conventions of nurserymen and florists would be well worth attending for this single purpose, even if they were not made attractive by pleasant social features, by opportunities for enlarging acquaintance, by offering a timely period of recreation after the busy season has passed. No doubt they will prove more useful still in many directions as they become more thoroughly organized. They might render good service to horticulture by a systematic effort to secure uniform and correct nomenclature of trees and shrubs. It would be directly in the line of their labors to devise some plan for the better classification of cultural varieties of the different fruits and some comprehensive system for describing and identifying them. They might collect data from various stations in the country as to what fruit and ornamental trees are reliable in different sections and what ones are likely to fail. Indeed, there are fields without number towards which they can direct united effort, and so many skilled cultivators scattered over so wide a territory and working for a single purpose could hardly fail to accomplish results of lasting importance to horticulture or pomology.

Walks and Drives.

THE walks and drives play an important part in determining the effect produced by villa-grounds and country places. Whether composed of gravel, asphalt or simply of earth, they form wide lines, distinct from their surroundings in color and texture, drawn through lawns and shrubberies. As such they are conspicuous features; they are features, however, which have no real beauty in themselves, and, therefore, they should be used with care and discretion.

It is desirable to limit them as much as possible—to make them neither more numerous, nor wider, nor longer than necessary. Too often we see in small places a walk almost wide enough for a drive, and a drive almost wide enough for a park-way; a drive where a walk would have served every purpose, or walks which serve no purpose at all. It is no infrequent thing to find, instead of a fine stretch of lawn, an assemblage of winding paths, leading nowhere except back to the houses again, with small scraps of turf between them. Unity of effect is ruined by such an arrangement and no practical end is served. If for any reason the borders of the lawn are often visited, the turf itself may be walked on, for, unless exactly the same track is perpetually followed, a great deal of walking will not injure it. And if it is objected that the circling paths give access to the flower-beds with which they are bordered, the answer must be that the flower-beds are as much out of place upon a lawn as the paths themselves. Of course in a flower garden it is different. There the beds and the walks leading to them are the main concern, and whatever grass exists may rightly be subordinated to them. But if it is desired that turf shall preponderate in the effect, then the less it is cut up and disturbed the better. There is nothing more beautiful in itself, and nothing which gives so marked an expression of size, unity and restfulness to a place as a wide sweep of lawn. In the majority of cases it is better worth striving for than anything else;

and it should be jealously preserved from the presence of any accessories except those which may serve to enhance its proper character and increase its apparent size. It may be surrounded with trees and shrubs, and, if it is of considerable size, a few isolated specimens may be brought forward from such bordering plantations. But a lawn must be very large to admit of any other decoration.

In his suggestive article in our issue of June 6th, Mr. Olmsted pointed out the mistake which is so often made in demanding that the best rooms of the house shall be on the entrance front. One great reason why they should not be, is that they should have the best outlook, that either a drive or a walk must give access to the entrance front, and that no matter how simply treated it may be, it cannot fail to detract from the reposeful character of the outlook. Nevertheless we often find that even when the lawn front of a house is not the entrance front, a walk is carried past the lawn entrance or by the piazza or the windows facing the lawn. A greater mistake could not be made than this. The smallest stretch of gravel or naked earth brought thus into the immediate foreground disturbs the effect from the house of the green expanse—injures its restfulness and decreases its apparent size. And looking towards the house the injury is as great as when we look out from it. Nothing is more pleasing to the eye than the foundations of a house springing from the green turf, clothed with vines and broken with low-growing shrubs. Then that most charming of all effects is secured—the effect of intimate union between the soil and the building it bears—between Nature's work and man's work. But the smallest line of gravel will ruin this effect if it runs parallel with the walls of the house. And the lawn itself will look infinitely more beautiful if there is no walk running away from the house and cutting it in two. There can rarely be a need for such a walk when the lawn front and the entrance front are not the same. Even if a flight of steps leads down to the lawn from porch or piazza, no path is necessary unless there is a strong temptation for feet to follow one another in a given direction. If this is the case, however, a gravel walk is, of course, preferable to a trodden track, which gives an air of neglect to a place. But such a walk should be as short as possible, and it should not be bordered with flower-beds.

When a place is quite small it is best to make all drives and paths straight if possible. The drive, if there is one, should not approach the street front of the house, and should be carried to the entrance elsewhere in as direct a line as convenience will permit. Or if entrance front and street front are the same let there be no drive, let the gate be opposite the door, and let the path run in a direct line between them. Of course, if there are irregularities in the surface of the ground they should determine the course of paths; but such cases are comparatively rare, and in all others there are many reasons why the straight line should be preferred. Every foot of grass is doubly valuable in very small grounds, and a straight path absorbs fewer feet than a sinuous one; it is difficult to give a graceful form to a sinuous line unless it is of considerable length; when the house walls and the street line lie near together their straightness seems to prescribe that, in the interest of harmony, the connecting line between them shall be straight as well; and the straight line is more simple in effect, and simplicity is the greatest of virtues in the arrangement of small grounds.

We learn from the *Prairie Farmer* that the farmers of Iowa have suffered considerable loss from a disease of their nursery stock of Apples, Plums, Rose and other plants. The disease shows itself in the formation of excrescences on the roots which are popularly called "cancers." The origin of the trouble is obscure, some attributing it to insects and others to fungi. There is probably no good reason for thinking that the trouble is due to insects, and, as far as fungi are concerned, Professor T. J. Burrill, who has examined diseased roots from Iowa, states that,

although there is a considerable growth of the mould-like filaments of some fungus and swarms of bacteria on and in the exterior cells of the old bark, no one can say from this evidence that either of these causes the trouble, and he infers that, if the cause is a fungus, it comes rather from the soil than directly from a diseased plant to the healthy one.

The Cultivation of Truffles.

THERE are two things, truffles and terrapins, which no one dares to dislike, for, even if they are not exactly to our taste, they are always expensive, and we are, of course, willing to make martyrs of ourselves by pretending to like delicacies which only the favored few can afford to set before us. But there are a good many genuine admirers of truffles in America as well as in France, and they will be interested in two recent books on the cultivation of truffles—"*Manuel du Trufficulteur*," by A. de Bosredon, and "*La Truffe*," by Dr. C. de Ferry de la Bellone. Of the two, the last-named is the better from a scientific point of view. M. Bosredon, whose style has a touch of Daudet about it, begins with an account of an interview with an aged rustic, *Père Chenier*. The sententious *Père Chenier* wags his head gravely and enunciates the fundamental law of truffle culture: "*Semez des glands, vous récolterez des truffes.*"

The discovery of the law that, if one sows acorns, he will gather truffles, a discovery which has enriched many owners of barren land in some parts of France, was made by accident about eighty years ago. The growth of the truffle has always had an air of mystery about it. When one wants a crop of beans he sows beans. But the case of the truffle may be compared roughly to what would happen if one should get a crop of beans by planting bean-poles. The explanation of this anomaly is well stated in "*La Truffe*." Every one knows that truffles grow underground, and are hunted, if one may use the expression, by pigs and dogs whose scent is acute. At first, they were not even supposed to be plants at all, but later they were believed to arise from the punctures of roots by insects, still later, to be morbid conditions of the roots themselves, and now they are known to be fungi which are probably parasitic on roots of different trees, especially Oaks.

Unfortunately, *Père Chenier's* law applies only to regions where truffles occur naturally, and there, by sowing acorns of trees growing in truffle-bearing regions, there can be produced in a few years, seven to ten, crops of truffles which continue so long as the trees are in good condition. Fortunately for the French, the best soil is a thin, calcareous one not of much value for other crops. Dr. Ferry gives a chart showing the localities where truffles can be grown in France, and practically they are cultivated nowhere else. As all champagne comes from Champagne, so all truffles come from Perigord—at least, the labels say so. There is a considerable number of species of true truffles which belong to the *Tuberaceæ*, a sub-order of *Ascomycetes*, not to mention the false truffles which belong to the *Gasteromycetes* or puff-ball family, and a pretty full account of them is given in "*La Truffe*," together with some figures which, of course, are not to be compared with the superb plates in Tulasne's classic "*Fungi Hypogæi*."

Commercial truffles have not yet been found in the United States, although a few species of the truffle family have occasionally been found by botanists in the Eastern and Southern States. California seems to be much richer in *Tuberaceæ*, and Dr. H. W. Harkness has detected a considerable number of species in that State. Apart from their rarity, the American species, so far as known, cannot compete in flavor with the French, and it is hardly likely that truffle culture will soon be undertaken in the United States.

Dr. De Ferry's book is full of interesting details. We

have heard of fat pigs, learned pigs and precocious pigs, but it was left to his sympathetic pen to portray the well-bred, conscientious, pains-taking pig, the pig whose superior education alone makes him worth from sixty to seventy dollars. This comparison of the mental, and, if one dares to say so, the moral qualities of pigs and dogs, would delight any comparative psychologist. It is also interesting to read of the tricks of truffle poachers and the intricacies of the laws for their punishment. Nothing seems wanting, except, perhaps, some notice of the lives of the distinguished *gastromomes* whose talents were unselfishly devoted to the preparation and digestion of truffles. Even art is made to contribute to the value of the book, the frontispiece being a reproduction of M. Paul Vayson's Truffle Hunter, exhibited in the Salon of 1886.

W. G. Farlow.

The Domestication of Wild Fruits.

THERE are two reasons why we should attempt the improvement of our more promising wild fruits. First, there is a prospect that they may become valuable additions to our orchards or gardens; and second, the culture of these fruits offers a favorable opportunity to study the influence of changed conditions upon the characters and properties of these plants.

Regarding the first of these propositions we are not justified in assuming that all the fruits not now in cultivation are incapable of improvement. To argue that they must have been tried and found wanting in prehistoric times, because history gives no record of their cultivation, would be quite unwarrantable. Neither are we justified in assuming that because no attempt has been made to improve them, success is sure to follow systematic efforts. Our knowledge is hardly sufficient to prophesy what may be the outcome in submitting any given wild fruit to the experiment of systematic and prolonged cultivation.

To the scientific horticulturist the second proposition offers a more hopeful field of labor than the first. Whether the attempt to domesticate a wild fruit proves successful or not, from an economic point of view, it can hardly fail to add to our knowledge. The origin of our cultivated fruits, and especially the degree of their present excellence that may be ascribed to man's aid, is, to a considerable extent, involved in obscurity. The submitting of a hitherto untested wild fruit to cultivation, and the systematic study of the changes that result from such treatment, may throw light upon the historical development of our present cultivated fruits, and what is of still greater importance, it may furnish valuable hints for their further improvement.

The Juneberry (*Amelanchier Canadensis*), in some of its varieties, possesses qualities that commend it for experiments in domestication. It belongs to the Rose Family, and is thus botanically related to the best fruits of temperate climates. The plant is hardy, prolific, and exhibits remarkable variation. The fruit in its best natural state is of fair quality, attractive in appearance, sufficiently large to admit of convenient gathering, firm enough to bear carriage; and it keeps for a considerable time after being picked. In stature the species varies from a low shrub to a tree thirty to forty feet in height, and forms, grouped within the same botanical variety, sometimes exhibit nearly as much variation in height. The fruit is often very small, dry and seedy, and utterly worthless for any economic use; but in certain varieties it attains a diameter of fully half an inch, is sweet, fairly juicy, and delicately flavored.

Thus far, the finest fruit has been found on a form which is said to have come from the Rocky Mountains, and which is the only one I have attempted to cultivate. It appears to have been first brought to public notice by Dr. Hall, of Davenport, Iowa, who grew it and advertised the plant for sale about ten years ago. Mr. Benjamin G. Smith, of Cambridge, introduced it into Massachusetts, and received a silver medal from the Massachusetts Horticultural Society for it. Through the courtesy of Mr. Smith

a few plants of this variety were sent to the New York Agricultural Experiment Station in the year 1882.

These plants, which were well rooted layers, were set out in a moderately fertile clay loam, and have since received the same culture that is given to Raspberries. They have now grown into rather straggling shrubs about four feet high, though Mr. Smith states that on his grounds plants set some years earlier have attained the height of six feet. The shrub appears perfectly hardy in the climate of Geneva. It varies considerably in productiveness in different seasons, but during the past three years has borne at least a fair crop. The fruit, a miniature pome, varies in size from a fourth to a full half inch in diameter, and in its external appearance bears a striking resemblance to that of the Huckleberry, being deep purple in color, and having, like that fruit, a persistent and protruding calyx. The flesh is white, or slightly pinkish, and has a peculiar delicate, faintly aromatic flavor that is not in the least unpleasant, although lacking in intensity. With sugar and cream, the flavor is perceptibly heightened, and some persons who have tasted it in this way call it delicious. The seeds are small, soft, and though inclosed in carpels, are little noticeable in eating the fruit.

It should be said that this plant is not without its enemies. A fungus, *Rastelia penicillata*, attacks the foliage and fruit in some localities, though I have not seen it at Geneva. The curculio infests the fruit to some extent, and the English sparrow takes his share, but all these obstacles have not prevented good crops from our trial-grounds.

The most promising field for improvement in this fruit doubtless lies in the growing of seedlings, and in the crossing of varying forms. I have made sufficient experiments to demonstrate that the seedlings may be very readily grown; and I have a considerable number now on trial, though none of them have fruited as yet. I hope to secure plants of other varieties, and from distinct localities, in order to try the effects of cross-fertilization. One reason why I have been especially interested in this fruit is that it offers an opportunity to test a hypothesis. I have been struck by a coincidence that in almost all our fruits and vegetables, a pale flesh is accompanied by a mild flavor, while a dark-colored flesh is accompanied by a rich flavor,* and in fruits that contain much acid, the acid almost always increases with the depth of color in the flesh. The fruit of the only form of the *Amelanchier* with which I am well acquainted has a white, or very nearly white, flesh, and while the flavor is, as has been stated, quite delicate, it is too little marked to render the fruit generally popular. If by growing seedlings, or by cross-fertilization, we can secure varieties that have a darker-colored flesh, I should expect that they would have a more pronounced flavor, and might then rank among our delicious fruits. It is in this direction that I am chiefly working.

Geneva, N. Y.

E. S. Goff.

New or Little Known Plants.

Pitcairnia Jaliscana.†

THE order *Bromeliaceæ* is scarcely represented within the limits of the United States aside from the few species of *Tillandsia* which are found in Florida, and the Spanish Moss (*T. usneoides*) which drapes the trees so abundantly in the swamps and river bottoms of the South from the Dismal Swamp in Virginia to Texas and Mexico. In the extreme western borders of Texas a single species of *Hechtia* has been found as an outlyer of the Mexican flora, and in southern Florida a West Indian species of

*A paper giving a large amount of data bearing upon this subject was contributed by the writer to the *American Naturalist*, for 1884, pp. 1203-1210.

†PITCAIRNIA JALISCANA, Watson, Proc. Am. Acad., xxii. 456. Acaulescent; basal bracts spinosely margined, and with attenuate, barbed appendages; produced leaves furfuraceous beneath, entire, linear, a foot long or more, by three or four lines broad; flowering stem glabrous, with numerous bracts; floral bracts mostly colored, dilated, much longer than the erect pedicels; petals scarlet, linear, nearly two inches long, twice longer than the acuminate colored sepals; stamens and style slightly exerted.

Catopsis; and these are all. The genera with more showy flowers than these, such especially as *Billbergia* and *Pitcairnia*, are more strictly tropical in their character. *Pitcairnia* is, next to *Tillandsia*, the largest genus of the order, and its seventy-five species are found mainly in the region lying east of the Andes from Brazil to Mexico, while none occur outside of the tropics. On account of their highly ornamental flowers a very large proportion of them have been in cultivation in the gardens of Europe, but they are rarities in our own hot-houses.

We have figured for this week (page 197) one of two species of *Pitcairnia* which were discovered by Dr. Edward Palmer in 1886, near Guadalajara in Mexico, the most northern locality on the continent for any member of the genus. The striking colors of the flowers and bracts cannot be shown, but most of the other characters are well represented. The short outer bract-like leaves that cover the swollen base of the stem are prolonged, as in many other species, into slender appendages which are very sharply barbed. The plant is otherwise unarmed. The few proper leaves are long and linear, and are covered on the under side with a white, scurfy pubescence. The floral bracts are mostly of a deep rose color, and the flowers themselves are bright scarlet. Heat and drought are the delight of these plants, or at least they are capable of enduring and thriving under an extreme of both. The present species was found growing in the crevices of rocks in deep, hot ravines, and would probably need, like the rest of the genus, the heat of a stove for its successful cultivation. S. W.

Cypripedium bellatulum is the name given by Professor Reichenbach to a new species which is closely allied to *C. Godefroya*, and which might fitly be described as a giant form of that fine species. The flowers are described by Messrs. Hugh Low & Co. as nearly four inches across, and many of the leaves are ten inches long, and more than one-fourth as wide, and marked as finely as those of *Phalenopsis Schilleriana*, while their under surface is purplish red throughout, or marbled with deep red. The flowers are of perfect shape and profusely spotted.

Plant Notes.

Prunus pendula.

THE tree which is figured on page 198 of this issue is one of the loveliest in flower, and the most pleasing and graceful in habit of all the plants which have been transferred from the gardens of Japan to those of this country. It is the *Prunus pendula** of Maximowicz; a species first described by Von Siebold in his "*Synopsis Plantarum Japonicarum universi regni Japonici*," a work which, unfortunately, I have been unable to find in this country. M. Franchet has kindly examined, however, the copy of this rare book in the Paris Museum, and informs me that Von Siebold in his description of the plant retained the Japanese name *Itozakura*, that is pendulous, for this species, so that Maximowicz, instead of adopting Von Siebold's specific name, translated it into Latin, changing his *Cerasus Itozakura* into *Prunus pendula*. Were the laws of botanical nomenclature rigidly adhered to, it should be known as *Prunus Itozakura*, a change which, under all the circumstances of the case, it is certainly not desirable to make, at least for garden purposes.

Prunus pendula, as now seen in gardens, has probably been somewhat changed by long cultivation from the wild type; indeed, specimens of what is evidently the same plant collected in the forests in the central part of Nipon vary very considerably from it in the length and breadth of the calyx-tube and in the much smaller corolla. Here it is a small tree twelve to fifteen feet high, with wide-spreading, flexible, pendulous branches, those on the lower

part of the stem horizontal, with pendulous ends, the upper widely arching from the trunk. The bark resembles that of the common Cherry tree, although light brown in color. The flowers, which precede the leaves, are produced from scaly, lateral buds in two to four flowered fascicles. They are borne on long, slender, pubescent pedicels, which are destitute of bracts. The tubular calyx and incised calyxlobes are densely pubescent and dark red in color. The petals are half an inch long, ovate or obcordate, pale rose colored, and more than twice as long as the stamens. The ovary is slightly, and the style is densely, covered with long, nearly white, hairs. The leaves are three or three and a half inches long, slightly hairy, when young, on the under side, twelve to fifteen ribbed, ovate and longly acuminate, sharply glandular-serrate, with two conspicuous glands near the base of the blade. The stipules are linear, glandular, and, like the short petioles and young shoots, pubescent. The fruit is black, the size and shape of a pea.

A second species of *Prunus* (Fig. 37), very similar in general appearance to *Prunus pendula*, is confounded with it in gardens here. It has the same general habit and the same long, pendulous branches, but the bark is darker, and hardly to be distinguished from that of the common Cherry tree. The flowers are corymbose on short leafy branches, and the pedicels are conspicuously bracted at the base, and, as well as the shorter and paler calyx tube, are covered with a few scattered hairs. The petals are more narrowly ovate than those of the last species, entire and rarely truncate, much paler pink or nearly white in color. The ovary is quite smooth, but the style is densely coated with hairs. The leaves which appear shortly after the opening of the flowers are broader, thinner and more deeply and irregularly cut on their margins and are only 6-8 ribbed. They are pubescent on the under side, as well as the petioles and young shoots, and have two conspicuous orange-colored glands at the base of the blade. Their larger stipules are three-lobed and glandular. The corymbose inflorescence of this plant, the forked stipules and the texture and color of the young leaves point to some form of *Prunus Pseudo-Cerasus*, but the style is conspicuously hairy, and I therefore very doubtfully refer it to Maximowicz's *Prunus Miqueliana*,* authentic specimens of which, however, I have not been able to examine.

The two species are cultivated in nurseries under the name of *Cerasus Sieboldii pendula flore roseo*, and *flore carneo*.

Under the name of *Cerasus Herinquiana* M. Lavallée described and figured in his *Icones*, t. xxv., a plant which seems identical with the second of these two Cherries.

These plants were sent to the Arnold Arboretum several years ago from one of the Dutch nurseries. Both species flower here every year and are exceedingly hardy, requiring no special care or cultivation. They can be increased by grafting upon the common Cherry. The grafts should be inserted close to the ground in order to secure the peculiar habit and full beauty of these trees. When grafted as standards, as is often the case in nurseries, they are then less graceful and lose much of their peculiar habit of growth.

Our illustration is from a fine specimen on the estate of Arthur Blake, Esq., in Brookline, Massachusetts.

C. S. S.

The finest varieties of the common Lilac (*Syringa vulgaris*) in the large collections in the neighborhood of Boston are Philamon and Marie Lagrange. The former has large, broad, compact panicles of dark purple-red flowers, nearly half an inch across the limb when expanded. This has the deepest and richest colored flowers of all the Lilacs. Marie Lagrange has very large pure white flowers in immense panicles. Both varieties are of European origin; and they grow rapidly and vigorously, and soon make fine specimens.

Thinning Fruits.

THE systematic thinning out of fruit has hardly received the attention it deserves, either at the hands of commercial growers or of amateurs. The former class particularly argue

seasons some varieties of fruits set far more than the trees can fully develop and mature. In such cases natural or artificial thinning must be resorted to, to secure satisfactory results. The army of curculios, codlin moths, birds and fungi assist in this matter with great energy, but generally with little discrimination. And yet without their aid, it must be confessed that the fruit grower would often find thinning an imperative duty.

If half the crop of Apples, Pears or Peaches on a tree were removed, those remaining would frequently aggregate as much in bulk as the whole would if allowed to remain, and would probably yield as much money, to say nothing of the diminished labor of handling. Again, well grown fruit meets a readier sale. Such Pears as the Seckel, which grow in clusters, can be thinned with decided benefit, and perhaps it is the small varieties generally that pay the best for thinning, as increase of size is more readily appreciated in the smaller kinds. Apples and Pears which incline to cluster, even in twos, are generally more defective, by reason of insect depredation, than those borne singly. The Beurré Bosc is one of the latter kind and not prone to overbear, and if attacked by insects, it is generally in the calyx. The Bartlett, when well set, is in pairs and triplets, and the point of contact is generally the seat of insect operation. The early thinning of these clusters to single specimens, therefore, gives fairer and larger fruit for the trouble. On the other hand, Marie Louise has never borne for me a fine flavored specimen except on a light crop; with a full crop, even when severely thinned, they attain cooking qualities only, which is even more than I can say of the Mount Vernon. Indeed, it is yet an unsolved problem with me whether the lightest kind of a crop of the latter would give me specimens of tolerable table quality. Clairgeaus are very prone to overbear here and thinning is an absolute necessity if their quality is to be brought above mediocrity.

Peaches can be fairly thinned by pruning the trees, which is the most feasible method. But when this is neglected and the trees are full set, the removal of half to two-thirds of the fruit, after the natural dropping is over, will be found beneficial, not only enhancing the size, quality and value of those remaining, but saving the tree from breaking down. With Peaches it is size that tells, and the larger the Peach, the greater the proportion of flesh to stone. A friend in California writes that the Peach trees there did not contain more than one-third as many as lay on the ground after the Chinamen had completed the work of thinning. With Chinese labor here, or his rate of wages, this question of profit in our large Peach areas, with their enormous products, would still be a debatable one, and whether our markets would stand a sufficient advance in prices to compensate for the increased expense, is, to say the least, problematical.

Thinning Strawberries is sometimes practiced to secure extraordinary berries for exhibition, but the only practical way to improve the quality of the crop is to thin the plants. If allowed to run in thick matted rows they generally become too crowded for the best results, and many plants must, of necessity, become weak and unfruitful. No better evidence of this fact can be adduced than to compare the crop on plants grown in hills with the same number of plants in thick matted rows. The hill system means extra labor, it is true, but the improved quality of the crop will go far to compensate for it.

Pruning is also the best method of thinning and improving the quality of the Grape crop. With judiciously pruned vines to start with, the after thinning is simple and easy. All that is required is to rub off the superfluous buds and shoots. A vine producing twenty-five pounds of fruit in clusters of half a pound and upwards, would bring more money than one producing the same number of pounds in clusters of one-quarter of a pound each, give more satisfaction to the grower for home consumption, and save labor and time in gathering.

The sum of the matter is, that in most cases, larger, more

Fig. 35.—Pitcairnia Jaliscana.

that in the case of large trees it is often impossible, and that even when it can be done, the time and labor expended bring no corresponding profit. I am inclined to think, however, that when it is intelligently practiced the thinning of fruit almost always pays, and often pays large returns. In favorable

beautiful and finer fruit can generally be raised when a very considerable portion of the sets are removed. Apples or Peaches when crowded closely along a limb are no more able to attain full development than Beets or Cabbages when set too closely in a row. It will generally pay to reduce the number of sets in some way. The exceptions in the case of Pears, mentioned above, simply prove that some varieties will not respond to this treatment in some places. These facts the fruit grower must learn by experience. The commercial grower raises fruit for the profit. He must study his market to know how far his gain from increased quality will warrant the increased expense of thinning. The amateur, who prides

fortunate that they have so generally gone out of fashion. When grown as standards to the height of two or three feet they make plants of striking beauty. They are all rapid growers, and need a liberal supply of water when making wood and flowers. A correspondent of the *Gardener's Chronicle* makes the following selection of varieties from a large collection at the gardens of the Royal Horticultural Society at Chiswick.

One of the freest and strongest grown is named *Ver Luisante*; orange-red with orange centre, deepening in color with age; the young flowers open orange, and deepen in color as they mature. This would make a good exhibition specimen when well grown. *Le Styx* has very fine,

Fig. 36 *Prunus pendula*

himself on fine specimens for exhibition, or for his table, does not stop to consider the financial side of the question. He simply takes the necessary steps to secure what he wants. His labor in this direction is often really a pastime, and if he does not reap his reward, in his satisfaction from day to day, he is pretty certain to do so when his crop matures. Those who have not studied and experimented in this field will be surprised to find that in many cases the very finest fruit is produced only after thinning has been carried on to an extent that would seem to the novice most extravagant.

Montclair, N. J.

E. Williams.

Lantanas.—These are properly classed among green-house plants, but they make admirable bedding plants, and it is un-

rich, deep orange-red flowers, produced in large and bold trusses; it is a very free grower also. *Mons. Boucharlat* has fine and showy pale orange flowers; the individual blossoms are large, and they are produced in very fine trusses that are bright and striking; it is a remarkably good grower also, being strong and robust. *La Patriote* is a very pretty variety; the flowers open pale golden-orange, changing to pink, and with a rosy-pink centre; a fine and distinct variety. *Venusta* is salmon-colored with orange centre; very fine in the pip and truss; distinct, and very good. *Clio* opens gold, and gradually changes to lovely rosy-purple; fine pip and truss, and a good, free grower. *Triomphe du Commire* is of a pale lilac-pink color, deepening in color with age; fine pip and truss, and it can safely be marked very good. *Grisette*

is lilac and mauve, tinted with rose; the flowers open pale lemon, and change to the above; it is a good grower and very free. *Rosa Mundi*, rosy-purple, is very pretty indeed. *Souvenir d'un Ami* opens gold; the flowers then become orange-salmon, and finally the salmon deepens to rosy-purple; very fine pip and truss, and good habit. *Comtesse de Beneval* opens yellow, and changes to pale rosy-pink; it is a very pretty and free variety. *Meteore* opens cream, and changes to pink and pale rosy-lilac; it is a pretty and pleasing variety.

Coming now to what may be termed the yellow-flowered varieties, probably the best is *Reveille*, deep yellow in color, very fine and free. *Pluie d'Or* is pale golden-yellow, flowers and trusses alike small. *Figaro*, bronzy-yellow, is very free of bloom also. *Bijou*, orange and gold, is of dwarf habit, very free, and makes an excellent pot plant. *Grappe d'Or* is of a fine hue of gold, very dwarf in growth, and exceedingly free. *Californie* is of a distinct pale yellow color, good close habit, and very free indeed.

One of the best whites is *Innocence*; it opens pale lemon or

side, and this will be especially beneficial if the bark shows signs of loosening or peeling off. Sprinkling the tree occasionally will help to check too rapid evaporation; to the same end the surface of the ground should be stirred and mulched, but the branches should not be cut back to diminish the leaf surface.

S. A.

Why Vines Winter-Kill.—The hardiness of vines is generally based on the ability to pass through the winter safely, but the ability to do so is dependent on their condition in the fall when they go into winter quarters. In my vineyard are numbers of vines of Roger's Hybrids, such as *Wilder*, *Lindley*, *Merrimack*, besides *Niagara*, *Brighton* and *Pocklington*, that appeared when pruned in December to be thoroughly ripened and matured so far as we could judge. Many of these this spring are winter-killed, even to the root in some cases. This condition is unquestionably due to mildew. These vines that were mildewed most are injured most, while other vines of the same varieties that escaped this scourge are budding to the re-

Fig. 37.—*Prunus Miqueliana* (?)

primrose, then changes to white; of good habit and very free. *Bouquet Blanc* is yellow, changing to white. Lastly comes *Le Lis*, which opens pale yellow, and changes to pure white; good habit and very free. Perhaps, taking all things into account, this is the best white grown.

The best dozen varieties, selected from the Chiswick trial, will be found in *Ver Luisante*, *Le Styx*, *Mons. Boucarlat*, *La Patriote*, *Venusta*, *Clio*, *Triomphe du Commire*, *Comtesse de Beneval*, *Reveille*, *Bijou*, *Innocence* and *Le Lis*.

Newly Transplanted Trees.—Young trees that were transplanted this spring generally look well, because of abundant rains, but it should be remembered that dry weather may come and with it comes danger. A vigorous growth of new shoots is proof that healthy new roots have formed, and that they are furnishing all the moisture needed to supply the leaves. But where there is little new growth, or none at all, it may be inferred that the root growth is small and unable to supply the tree with sufficient moisture. In such cases it is good practice to wrap the trunks, or shade them on the south

most extremities. Winter hardiness is dependent on summer hardiness, and the latter is of most importance.—*Orchard and Garden*.

Notes from the Rock Garden.

THE handsomest flower in the Rock Garden this week is the Siberian Columbine (*Aquilegia glandulosa*), the earliest of the genus to flower here, with the exception of the native *A. Canadensis*. It is a dwarf species growing eight or ten inches high, the flower stems each with one to three flowers, which have bright blue sepals fully an inch and a half long, pure white petals, and short and very stout, incurved spurs. The Siberian Columbine is perfectly hardy, but it is a plant of rather delicate constitution, or rather it is short-lived, and in order to obtain the best results it should be treated as a biennial and not depended on to flower more than once. If the seed is sown very early in the spring (it is better to sow it in heat during winter), the plants will be strong enough to transplant

early the first season into nursery rows, and then they can be transplanted again in the autumn into the rockery or herbaceous border, where they will bloom the next spring. Few plants better repay this trouble.

Thermopsis fabacea is a hardy Siberian perennial Pea, with pale foliage, and tall, erect racemes of large, clear-yellow flowers, which is just now in all its beauty. It spreads rapidly from underground shoots and is almost too rampant in its growth for the rockery, and is better suited to a large herbaceous border, where, if left undisturbed, it will soon spread over a considerable area.

Tiarrella cordifolia, known as the false Mitre-wort from its resemblance to its near relative the *Mitella*, is now a beautiful object in the shady parts of the rockery, where it is well established and thoroughly at home. It is a member of the Saxifrage Family, with heart-shaped, hairy leaves sharply lobed and toothed, and a solitary, slender, leafless scape a foot high, bearing a simple raceme of small, pure white flowers. The False Mitre-wort is found in cold, northern woods and on the Alleghany Mountains.

The small, yellow Lady's Slipper (*Cypripedium parviflorum*) is in flower. It is a pretty species, much smaller in all its parts than *C. pubescens* mentioned last week in these notes, rarely growing more than a foot high. It has a bright yellow lip flattened above and darker brown sepals and petals. The flowers are fragrant. It is a not infrequent inhabitant of northern bogs and wet woods.

Clintonia borealis is a stemless, perennial plant of the Lily Family, which recalls to the lovers of nature the name of De Witt Clinton. It is now in flower in a shady corner of the rock garden. The flowers are greenish yellow, half an inch long, with reflexed segments, and are produced in a few-flowered umbel, upon a low, slender, naked scape sheathed at the base by the stalks of the large, oblong leaves. The blue, oblong berries which ripen in August are very ornamental. This pretty plant inhabits northern woods, and is found also in those which cover the Alleghany Mountains; it is easily transplanted into the garden, when, if in a shady position and deep, rich soil are provided, it soon becomes thoroughly established.

Ixiolirion Tartaricum, var. *brachyantherum*, is a variety of the well known *I. Tartaricum*, a native of central Asia, and a member of the Amaryllis Family. It is a very hardy bulbous plant of easy culture, with narrow, grass-like leaves, trumpet-shaped, deep blue flowers, with reflexed segments, two inches in diameter when expanded, and borne in a loose terminal umbel, upon a scape twelve or eighteen inches high.

The latest Tulip in bloom is the dwarf *T. Biebersteiniana*, grown in some foreign nurseries as *T. Persica*. It is a native of southern Russia, the Caucasus and Persia, extending as far east as Turkestan. The flowers are an inch and a half deep, bright clear yellow, with acute segments, the three outer ones being somewhat broader than the others and flushed with pale green on the outside. The yellow stamens are bearded at the base. The scape rarely exceeds six inches in height, bearing below the middle two or three narrow, pale, glaucous, channeled leaves. This is a very attractive little plant which should find a place in every collection of hardy bulbs.

Smilacina bifolia, or, as it is sometimes called, the Wild Lily-of-the-Valley, is a common northern plant with creeping root-stalks, often forming wide carpets, especially on rather dry knolls occupied by the White Pine and by the Oaks. It is a dwarf plant, three or four inches high, with two or rarely three heart-shaped clasping leaves, and short, single racemes of small, pure white flowers. It is easily cultivated and admirable for carpeting the shady parts of a rock garden, or to plant under shrubs and other taller growing plants.

Solomon's Seal (*Polygonatum multiflorum*) once was often found in American gardens, where at this season of the year it was a conspicuous and beautiful object. Now this handsome plant is so rarely seen here that it seems entirely unknown to people of this generation. Solomon's Seal has stout stems two feet or more in height, inclined to one side, alternate, ovate leaves, with pendulous, tubular, white flowers tipped with green, in axillary clusters. It is a bold and striking plant, well adapted for naturalization along the borders of shrubberies or wood-walks, where, if planted in deep rich soil, it soon makes broad clumps. *Polygonatum multiflorum* is widely distributed through central Europe and Russian Asia.

Few persons realize the beauty of our common wild Maiden-hair Fern (*Adiantum pedatum*) in cultivation, or know what a useful plant it is for a shaded rock garden, where it soon spreads and throws up a profusion of its graceful fronds. It bears exposure to the sun, too, and is an excellent pot plant for the summer decoration of rooms or piazzas.

Boston, May 30th.

C.

Notes from the Arnold Arboretum.

Prunus Jacquemontii is flowering here for the second year. It is a common plant in the drier regions of the north-west Himalaya from the province of Garwhal northward into Thibet and westward to Afghanistan, and is found at elevations varying from 6,000 to 12,000 feet. *Prunus Jacquemontii* is a shrub, which in the native country is said to attain a height of from six to ten feet, with long, slender, unarmed, divaricate branches, covered with pale gray bark. The leaves are two to two and one-half inches long, ovate or ovate-lanceolate, acute, sharply serrate, pubescent when young, on the mid-rib and primary veins, short petioled and destitute of glands. The flowers appear just before the leaves; they are solitary or often in pairs; very short pediceled, and quite cover the branches for several feet of their length. The tubular cylindrical calyx is about a quarter of an inch long, smooth, glabrous and striated, and twice the length of the acute lobes, which are hairy on the inside. The overlapping petals are bright pink, nearly circular, and about a quarter of an inch across. The ovoid ovary is quite glabrous, and is contracted into a long, narrow style. *Prunus Jacquemontii* has not produced fruit here yet; it is described as "globose, as large as the finger nail, red, juicy; stone nearly globose, a quarter to one-third of an inch in diameter, quite smooth." There is every prospect that this exceedingly interesting little Cherry will prove perfectly hardy in this climate, and that it will become a garden ornament of very considerable value. Dr. Aitchison, of the late Afghan Boundary Commission, who detected this plant in the Kuram valley and first introduced it into cultivation, in speaking of it says: "When the fruit is ripe and the plant is covered with it, which is usually the case, it forms a very pretty object in the landscape. It would be worth cultivating for ornamental purposes."*

The Dwarf Cherry of northern China (*Prunus humilis*) is in bloom. It is a low, delicate shrub, scarcely exceeding two feet in height, with virgate branches densely covered with pubescence during their first year, small, elliptical or obovate doubly serrate leaves, which are pubescent when young and small, pink or nearly white flowers, solitary or two or three together, and followed by small, edible, acidulous red fruit, rarely exceeding a third of an inch in diameter. It is a pretty little species, but less hardy and less valuable from a garden point of view than the closely allied *Prunus Japonica*, with which it has often been confounded, but which may be distinguished from it by its glabrous branches, ovate-lanceolate, long pointed, simply serrate, reticulate-veined leaves, and by its rather larger, deeper colored flowers. The double-flowered, white and rose-colored varieties of *Prunus Japonica* are not surpassed in beauty by any of the dwarf shrubs in the collection now in bloom; they are very hardy and are often seen in gardens. As these varieties of *Prunus Japonica* appear in garden catalogues under a variety of names, it may be an assistance to cultivators to add that to this species belong the plants grown under the names of *Prunus glandulosa*, Thunb.; *P. Sinensis*, Pers.; *P. Chinensis*, Blume, and *Amygdalus humila*, Sims. *Prunus Japonica* is a native of Manchuria and northern China as well as of Japan, where it is generally cultivated both in its single and double forms.

Prunus maritima, the Beach Plum, is a handsome plant when in flower, and one which is too seldom seen in gardens. It is a common coast-plant, from Maine to Virginia, often covering sandy dunes adjacent to sea-beaches. It is a low compact shrub, rarely more than three or four feet high, which is now covered with small white flowers, which in the late summer are followed by a profusion of handsome globular purple or scarlet fruit, which is collected in large quantities at some points on the New England coast and sold in the markets for preserving. This plant, although only found growing naturally in light sandy gravel, flourishes and flowers profusely when transferred to the garden. The little Wild Cherry (*Prunus pumila*) of the northern United States blooms here a few days earlier than the Beach Plum. The common eastern form is a low shrub, rarely reaching a height of two feet; but western plants sent to the Arboretum from the shores of Lake Michigan, near Chicago, have tall virgate, erect branches, six to eight feet high. This variety flowers nearly ten days later than the eastern plants, and reproduces itself from seed. The small white flowers, two or three together, are produced in the greatest profusion. The fruit is hardly larger than a pea, bright red and destitute of flavor. The Dwarf Wild Cherry is found on dry, rocky or gravelly banks or hill-sides, and is an excellent subject for planting in waste places, or for an

* Jour. Linn. Soc., xviii. 51.

undergrowth among other shrubs, or trees. It is very hardy, and easily cultivated.

The Ground Cherry (*Prunus Chamæcerasus*), with its small, glossy, coriaceous leaves, and small, abundant white flowers covering at this season of the year the long, slender branches, is a familiar object in many old-fashioned gardens in the United States, where it is generally seen grafted on a tall stem of the common Cherry tree, and forming a small and rather formal weeping tree. It is more attractive, perhaps, when grown naturally and on its own roots. It then becomes a graceful, low-branching bush, two or three feet high, gradually spreading over a considerable space. The Ground Cherry remains in bloom for a long time, and is perfectly hardy. A native of central and northern Europe and Russian Asia, it has been cultivated in gardens during more than three centuries. *Prunus avium*, the European Bird Cherry, the *Merisier* of the French, is in flower ten or twelve days later than the common Cherry tree (*P. Cerasus*). It is a handsome small tree, with ascending branches, coarsely toothed, soft leaves appearing with the large flowers, which are produced two or three together in sessile umbels, from lateral, scaly, leafless buds, and oval or ovate, dark red or black fruit. It is the origin of the Black Mazzard, the Black Heart and other garden cherries. A variety with double flowers, known since the days of Tournefort, should find a place in every collection of ornamental trees. The pure white, semi-double flowers are produced like those of the species with the leaves; they are composed of about 40 petals, thirty stamens and of an abnormally developed green abortive pistil. This is a smaller tree than the species, although equally hardy. It is sometimes known as *Prunus ranunculiflora* and as *P. avium multiplex*.

Some of the early flowering Hawthorns are in bloom. Of these the earliest and the handsomest is *Cratægus subvillosa*, a form, perhaps, of the exceedingly polymorphous *C. coccinea*, but, for garden purposes at least, sufficiently distinct to be considered a species. It is the largest of the Thorns growing spontaneously in the northern States, and one of the largest and most widely distributed of the American species, being found from eastern Massachusetts to Missouri and through the south-western States to the Sierra Madre Mountains of north-eastern Mexico. It is more common and better characterized west of the Mississippi River than in the eastern States, attaining, like several other species of this genus, its greatest size and beauty in the country adjacent to the Red River. *Cratægus subvillosa* is a round-headed tree, twenty to thirty feet high, with a stout short trunk, covered with light gray, scaly bark, rigid, smooth branches armed with long, stout, chestnut-brown spines. The leaves and broad foliaceous stipules are larger than on any other American Thorn; they are thin, glandular, especially on the petioles, roundish-ovate, cordate, wedge-shaped or truncate at the base, incised, and very sharply serrate, scabrous above, the lower surface, as well as the young branches, peduncles and calyx, densely tomentose. The flowers, in broad, flat corymbs, are produced in profusion; they are an inch or more across when expanded, pure white, the disk often bright scarlet. This species is, perhaps, more beautiful in the late summer than at this season of the year. Then it is loaded with large, bright, scarlet fruit, which is often more than an inch in diameter, and which is covered with a conspicuous bloom. The fruit of this species is the largest and by far the most showy produced by any of the Thorns which are hardy here. Unfortunately, it falls as soon as ripe, and long before the foliage takes on its brilliant autumn coloring. *Cratægus subvillosa* requires deep, rich soil in which to develop its greatest beauty. No other Thorn is more hardy here, or grows more rapidly into a handsome, shapely tree. *Cratægus Douglasii* is also in flower. This is the Thorn of the north-west coast, where, in the neighborhood of streams, it sometimes attains a height of thirty or forty feet. It is a handsome, round-headed tree here, worthy of a place in any collection, and interesting, too, in the fact that it is one of the very few ligneous plants peculiar to the coast region of Oregon and Washington Territory that is perfectly hardy in New England. It has stout, rigid branches, armed with short, stout, russet-brown spines, ovate, cuneate, coriaceous leaves one or two inches long, and small corymbs of white flowers a quarter to a third of an inch across, followed by small, black, edible fruit, which ripens here in August and soon drops.

Among foreign Thorns, *Cratægus sanguinea* and *C. nigra* are in bloom. The former is a widely distributed species through Siberia, Mongolia, northern China and Manchuria. It is well characterized by its broad, glandular stipules, shining, chestnut-brown, unarmed branches, smooth, purplish young shoots, and by the dark green, broadly-ovate leaves, wedge-shaped at the base, cut-toothed, and quite glabrous,

except in its axils of the primary veins. The flowers are white with purple stamens, two-thirds of an inch across when expanded, and followed during the summer by small, purple, or sometimes red fruit. This is a very hardy species, which becomes here a small tree, ten or fifteen feet high, well worth cultivating for its early flowers and handsome dark green foliage. It is the *Cratægus purpurea* of Loudon's Arboretum, ii. 822; and is well figured in Pallas' "*Flora Rossica*," t. 11. *Cratægus nigra*, a native of Hungary, is here a hardy and fast growing tree. It has pale green leaves, sinuately lobed, sharply serrate, broadly wedge-shaped or truncate at the base, and covered on the under side, like the young shoots, petioles, peduncles and calyx, with a thick white tomentum. The rather large creamy white flowers are followed by handsome black fruit, which hangs upon the branches until the late autumn.

The Tartarean Honeysuckle needs only to be mentioned here, that attention may be directed to the fact that it is one of the very hardiest of all shrubs, which might be more often grown than it is at present, in the extreme northern parts of this country. There are many fine varieties in the Arboretum collection with flowers ranging in color from pure white through pink and rose to red. The handsomest are from St. Petersburg, where a great deal of attention has, in late years, been given to the improvement of this shrub. *Lonicera Ruprechtiana* is a very hardy bush Honeysuckle, a native of Manchuria, which here forms a handsome, erect shrub, six or eight feet high by as much through, and which in its native country, according to Maximowicz, its discoverer, is sometimes a small tree 20 feet in height. It has ashy-gray branches, pale, ovate, blunt or acuminate, entire leaves, an inch or an inch and a half long, with prominent reticulate veins, slightly downy on the under side. The flowers, which have no perfume, are produced in great profusion. They are white at first, but soon turn light yellow or straw color, long peduncled, the slender tube of the corolla an eighth of an inch long and scarcely half the length of the narrow divisions of the limb. The beauty of the fruit of this species excels that of any Honeysuckle in the collection. It is a third of an inch in diameter, bright scarlet and almost transparent, remaining a long time on the branches. *Lonicera Ruprechtiana* is one of the most desirable of the perfectly hardy shrubs of recent introduction, and is well worth cultivating for the beauty of the fruit alone.

The Wayfaring-tree (*Viburnum Lantana*) is the earliest Viburnum in flower in the collection, although the Moosewood (*V. lantanoides*), a far handsomer plant, but the most difficult, perhaps, of all the American shrubs to establish in the garden, has been blooming in the cold, damp woods of the north for nearly two weeks. *Viburnum Lantana* is a stout, tall, much-branched shrub, very common through central and southern Europe, and perfectly hardy in this climate. It bears ovate, sharply serrate leaves, three or four inches long, cordate at the base, soft and velvety on the upper side, densely covered, as well as the young shoots, with white, mealy down. The small, white flowers in dense cymes, two or three inches across, are followed by handsome, purple-black, oblong fruit.

Two exotic species of *Amelanchier* are in bloom several days after the native species have shed their petals, *A. vulgaris* and *A. Asiatica*. The former is a dwarf shrub or more rarely a small tree, with roundish-oval leaves downy on the lower side, long petals and blue-black edible fruit. It is a native of the mountainous regions of central Europe. *A. Asiatica* is a small, graceful tree here, with long, slender branches with smooth, gray bark, ovate-elliptical, acute leaves densely covered, when young, with white wool, and compound racemes of handsome, pure white flowers. The fruit has not yet been produced here. This very hardy and desirable plant was found by Von Siebold in Japan, where it is very commonly cultivated in gardens and in the neighborhood of Temples, although probably a native of northern or central China. It is well figured in the "*Flora Japonica*," t. 42.

Staphylea trifolia, the eastern-American representative of the Bladder-nuts, is in flower. The drooping, raceme-like clusters of white, bell-shaped flowers are very pretty; but as an ornamental shrub for the garden it is in every way inferior to *S. pinnata*, a native of southern Europe, with bolder foliage, and larger clusters of pure white, fragrant flowers. This is one of the handsomest of the European shrubs which can be cultivated here successfully; and it should find a place in every garden. It is recommended as a good subject for forcing in winter. The Japanese *S. Bumalda* is very hardy, but the foliage is small and the flowers are much less conspicuous than those of the eastern American or of the European species, and it will not be often cultivated except as a curiosity. The very handsome and exceedingly rare species of northern California

(*S. Bolanderi*) has not yet been introduced into cultivation; and the *S. Emodi* is not in this collection.

The earliest *Elæagnus* in flower is the Japanese *E. longipes*, a handsome shrub, six or eight feet high, with pale green, oval punctate leaves, stellate pubescent on the upper side and covered on the silvery under side, when young, as are the new shoots, peduncles and corolla, with small ferruginous scales. The orange-colored flowers are long-stalked, with a long, slender tube and spreading limb, half an inch in diameter when expanded. The handsome, transparent, orange-colored, punctate fruit has an agreeable sub-acid flavor. This is a very hardy, free-growing plant well worth cultivation.

None of the evergreen *Berberis* (*Mahonia*) are very hardy in this climate, and they can only be grown when carefully protected in winter. The hardiest is *B. nervosa*, now flowering here for the first time. It is a dwarf evergreen shrub, with a smooth stem only a few inches high, producing from a terminal bud pinnate leaves one or two feet long the numerous acuminate leaflets palmately nerved, and elongated racemes of handsome yellow flowers. The oblong, blue fruit is a quarter to a third of an inch in diameter. *Berberis nervosa* is a native of the north-west coast.

May 30th.

7.

The Forest.

Forest Tree Planting on the Prairies.

AMONG the various methods of planting trees on the prairies, two have been recommended as more expeditious than digging holes for the roots and covering with the spade. One is to mark off the ground both ways as for a corn crop, and at the intersection of the lines to strike the spade down vertically, and then push the handle forward and backward, leaving a slit in the ground. Into this the tree is then inserted, the earth is pressed with the foot and the tree is planted. This method may do for inserting cuttings, or such trees as will readily root from the stems, but the roots will be cramped into an unnatural position, and aside from this, as the ground dries it will shrink, allowing the air to penetrate and destroy the crowded roots. I have examined many plantations made in this way, and never saw one—except in the case of Poplars—where there were not more dead trees than living ones at the end of the season.

Another method often recommended, is to mark the ground one way and plow furrows the opposite way, and then place a tree in the furrow at every cross mark, and plow the earth back over the roots. This is also an objectionable method, for it is not possible to plant all the trees at the proper depth, nor to tighten the roots properly. And even if that is attempted it will occupy more time than it would require to plant them with the spade. I never saw a plantation treated in this way that did not show many failures, and an unevenness in the growth of the trees, aside from being more troublesome to cultivate than if properly planted. All that is claimed in favor of either of these methods is that it is more expeditious than planting with the spade.

I will now describe fully, the method which long experience has convinced me is not only the best, but, all things considered, the most expeditious way, and the only way in which a great number of inexperienced workmen can be handled to advantage.

As many land owners who are not farmers plant forests on the prairies, I will commence with the prairie in its natural condition. It is very important that the prairie sod should be "broken" at the proper time, otherwise the planting will be delayed at least one year, and even then will not be in as good condition as if broken at the proper time.

Break the prairie in June or at the time the grass is in the most thrifty condition. Break quite shallow, not deeper than two, or, at most, three inches, as the greater the succulent growth and the shallower the breaking, the more surely will the sod be killed during the summer. Late in August and during September of the same year, turn the sod over lengthwise of the furrow, and deep enough to

bury the sod and leave two or three inches of earth over the entire surface. If it is not to be planted in the autumn leave the ground in this condition until the following spring, when the harrow and roller will put the land in excellent condition for planting. If planted in the fall run the harrow and roller after the plowing is finished, mark off the ground both ways for planting, strip the leaves from off the young trees, if frost has not already done so, then gauge the tree digger so as to cut the roots to the length required—six to eight inches, according to the depth and quality of the land—and commence planting.

The workmen are divided off into companies of three each, or two men and one boy, the two men with spades, the boy with a bundle of trees—the trees having previously been tied in bundles of 100 each. The two men with spades plant on adjoining rows, the tree holder walking between them. The planter strikes his spade vertically into the ground on the running line close up to the cross mark, raises a spadeful of earth, the boy inserts the tree, the earth is replaced, the planter places his foot close up to the stem of the tree, bearing on it his full weight—and passes on to the next mark. This tightening of the tree is very essential, and must be insisted on. The boy is kept quite busy attending two planters, but after a little experience he will learn to bring each tree out of his bundle with a quick circular motion that will spread out the roots when placed in the ground, about as evenly as they could be placed with the hand.

By this method the trees are planted in a straight line, and all at the proper depth, the roots are spread and the earth packed firmly over them. Two men and one boy will plant 4,500 trees in a ten-hour day, being two and one-half trees planted per minute for every man and boy employed, and the land will be left perfectly smooth and level for cultivating, making this not only the best, but the most expeditious way to plant forest trees on the prairie.

Robert Douglas.

Correspondence.

Northern Range of the Western Service-berry.

To the Editor of GARDEN AND FOREST:

Sir.—According to Sir John Richardson, the Service-berry (*Amelanchier alnifolia*), which was figured and described in your last issue, produces fruit in the Mackenzie Valley as far to the northward as lat. 65°. It appears to require not only a considerable amount of summer heat, but also a climate not very humid, and though present on Vancouver Island and found by me in 1878 in the Queen Charlotte Islands, probably attains its northern limit on the west coast at the last named places, as it is there of rare occurrence and depauperated in appearance.

The examination of the basins of the Stikine and Liard rivers and the head-waters of the Yukon, carried out last summer, afford some information on the occurrence of this species in the region between the west coast and the Mackenzie Valley. The *Amelanchier* was found in abundance, though as a small shrub only, near Glenora and Telegraph Creek (lat. 58°), in the Stikine Valley, to the east of the Coast Mountains, where the climate is dry and contrasts very remarkably with that of the seaward side of the same range. It was here in full flower about the 20th of May. It was again seen in the autumn on Tagish Lake, near the head-waters of the Lewes Branch of the Yukon, a few miles north of the sixtieth parallel and at a height of 2,150 feet above the sea. This locality holds a position similar to the last with respect to the Coast Mountains, and it appears probable that the *Amelanchier* may occur throughout the intervening country in favorable situations, though evidently near its limit on Tagish Lake, where the fruit seemed scarcely likely to ripen.

The *Amelanchier* was again found, farther inland, in the dry eastern lee of the Cassiar Mountains, growing on gravelly terraces along the Dease River (lat 59° 10', long. 129°). A line drawn to the northward of the various localities above mentioned will, I believe, define with near approximation to accuracy the north-western range of the *Amelanchier*, which is not mentioned in Rothrock's list of Alaskan plants nor in that of Dall.

From facts observed in several districts in British Columbia,

as well as in the Peace River country on the eastern slope of the Rocky Mountains, I believe that the degree and length of summer heat requisite for the development of this species closely corresponds with that necessary for the growth of wheat, and its distribution thus appears to possess a peculiar interest, regarded as a criterion of summer heat in places where cultivation has not yet been attempted. It may be mentioned that wheat has been successfully grown at Telegraph Creek on the Stikine and that barley is habitually cultivated there.

Ottawa, Canada.

George M. Dawson.

To the Editor of GARDEN AND FOREST :

Sir.—When trees are planted in a lawn shall the grass be permitted to grow directly around the trees, or shall a circular space be left around them ?

Shall trees be trimmed when they are first planted, and if so, in what manner ? Will it be necessary or advisable to trim them the second year ?

Providence, R. I., May 19th.

C. A.

[Trees, especially when first planted, will grow more rapidly if the ground about them is kept free from grass and weeds by frequent cultivation. A top dressing of well rotted manure spread over the dug space about the tree in the autumn, once in every two or three years, and forked into the ground the following spring, is an assistance to all deciduous trees. In the case of low-branching Conifers, like Firs, Spruces, and some Pines, standing in grass where the lawn-mower is used, it is a good plan to cut a circle in the turf a few inches wider than the lower branches of the tree. A tree protected in this way cannot be reached by the lawn-mower, even in the hands of the most careless workman, and its lower branches will be saved from mutilation.

It is a not uncommon practice to prune trees severely at the time they are transplanted. All the branches and a considerable part of the stem are cut away sometimes, especially in the country, and nothing but a bare pole planted. Trees mutilated in this manner often live, and sometimes eventually grow into fine specimens. The object of leaves is to elaborate sap, and the more leaves a plant carries, the more vigorously it will grow. It is a mistake, therefore, and an injury to the tree, to reduce its leaf surface just at the time when it needs all its vitality to overcome the serious shock which transplanting gives it. If a transplanted tree needs pruning to improve its form or to remove a dangerous fork in the main stem, or from any other cause, it is much better to wait for a year or two, until it gets a good hold of the ground, rather than to prune it at the time of planting. The subject of tree pruning in its various aspects will be discussed in the columns of this journal, and it is only possible at this time to say, generally, in answer to the inquiry of our correspondent, that the objects to be attained in pruning an ornamental tree are to so form the head that all the branches may be exposed to the light, to stimulate the growth of feeble and check the too rampant growth of vigorous branches, and to prevent the forking of the main trunk too near the ground, and so preserve it from splitting. The one rule which should be followed always in pruning a tree, is, that when a branch is to be cut off, it should be cut close to the trunk, so that no stub is left to decay and carry rot into the heart of the tree, and that when a branch is shortened, it should be cut back, for the same reason, to a lateral branch or bud. If this rule is followed a well established tree cannot be injured and often can be greatly improved by pruning.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—Can you kindly advise me what to plant to make a hedge against a fence about four and a half feet high which is shaded, but not at all densely, by a few tall Cherry and Ailanthus trees, and which faces the north-east ? Would Red Cedar do in such a situation ? I should prefer an evergreen hedge, but do not like the Spruce for this purpose.

New Brunswick, N. J.

I.

[The Red Cedar, the Hemlock, the Arbor-vitæ and the White Pine can all be used to make a hedge in New Jer-

sey. All these trees grow rapidly and bear cutting. Deciduous shrubs, however, as a rule, make better hedges in this country than Conifers, as they can better support the unnatural conditions to which hedge-plants must be subjected if they are to be kept to formal lines. The common Privet is one of the hardiest and most easily raised plants which can be used for a hedge. The Barberry makes a beautiful hedge, and so do Lilacs, Syringas, Tartarian Honeysuckles and other hardy garden shrubs. A hedge is a formal thing, which is beautiful only when it is uniform and regular and perfect; a hedge in which there are gaps or in which some plants are feeble and sickly is not an attractive object, and had better be cleared away and a new one planted, as it is almost impossible to repair an old hedge by inserting new plants. This is the reason why it is important to use only very hardy and carefully selected plants in making a hedge. It would be impossible, probably, to make a really good hedge under the conditions given by our correspondent. The overhanging trees will inevitably stunt the growth of the plants under them; and the hedge will present, therefore, a broken and unsatisfactory appearance, which cannot fail to be disappointing. An irregularly planted border of hardy shrubs in front of a fence is always better than a stiff, clipped hedge; and when, as in this case, the fence is overshadowed by large trees, an informal plantation is the only one which can be safely used. The common Barberry and some of our native Viburnums and Dogwoods will be found excellent plants to use in this way.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—In passing from woods to prairie here in Minnesota, some points in difference of climate are forced on our notice.

About November 20th, 1886, a foot of snow fell in the woods north of Minneapolis, while on the prairie, fifty miles west, the ground was not well covered.

On April 1st, 1887, in the woods, near Aitken, sleds were running with fair sleighing, and crossing the lakes with heavy teams as in winter; while on the prairie, near Fergus Falls, the seeders were going.

On April 23d, 1888, the dense Tamarack swamps of the Itasca basin held two feet of snow; while on the clearings, 100 yds. away, and on all the ground well exposed to sun and south wind, the ground was bare.

Recent Publications.

Pen and Pencil in Asia Minor; or notes from the Levant. By William Cochran. New York, Scribner and Welford.

This book, written by an Englishman who is a member of various British Agricultural Societies, is a combination of lively notes of travel with the serious and exhaustive discussion of an industry which the author has long been recommending to the notice of British colonists. Incidentally he gives interesting information with regard to the agricultural and fruit-growing possibilities of Asia Minor, especially as concerns the success which German colonists have had in raising the vine in the neighborhood of Smyrna. But his main object is to point out the possibilities and explain the processes of silk-culture as practiced in the Levant.

A long residence in China some twenty years ago convinced Mr. Cochran that the cultivation of the Tea-plant and of the Silk-worm might profitably be introduced in certain parts of Queen Victoria's dominions; and on his return to England he preached this belief so vigorously in the press and elsewhere, that, largely as a result of his words, Tea-farming was taken up on a great scale in Ceylon and in India. But the general adoption of sericulture in the east has been longer deferred, owing to the diseases which, for many years, had been raging among the silk-worms in China and which threatened the success of fresh enterprises of the sort. A few years ago, however, M. Pasteur devoted himself to examining these maladies and to providing a cure; and his lessons having been put in practice in the Levant, Mr. Cochran spent a season there for the purpose of studying the results. These, as seen in the large establishment near Smyrna of Mr. Griffith—who although an English citizen, has for many years been the consul of the United States—proved to be entirely satisfactory. In his present book Mr. Cochran exhibits this fact in a clear way, and gives full accounts, carefully illustrated, of the whole process

of sericulture as it passed step by step under his eyes. One chapter is devoted to the Mulberry and other trees the leaves of which have been used or experimented with as food for the silk-worm. The White Mulberry—*Morus alba*—always the favorite Silk-worm food in the east, is pronounced to be the best tree for this purpose, although the success in Louisiana with the Osage-orange is recognized; and the manner in which it is propagated and grown are fully explained. The ingenious way in which Mr. Cochran has sandwiched in his instructive chapters among those which record the merely picturesque incidents and sights of his voyage will undoubtedly attract to his book a multitude of readers who would not have cared for a mere technical treatise on sericulture. But simply as a treatise of this sort it well deserves attention from all those who, in various parts of the United States, have recently engaged in the silk-producing industry.

Recent Plant Portraits.

AMARYLLIS CONTESSA MARIANNA CAMBRAY DIGNY, *Bulletino de la R. Societa di Orticultura*, April; a variety with rather dingy red flowers streaked with white.

TEA ROSE, VICONTESSE DE WAUTIER, *Journal des Roses*, April; a handsome pink and very double variety raised by Alexandre Bernaix at Villeurbanne, near Lyons, an offspring of *Madame de Tartas*, fecundated by the pollen of *Anna Olivier*.

DICHORISANDRA PUBESCENS, var. *nov. Talmiensis*, *Revue de l'Horticulture Belge*, April; a handsome blue-flowered variety, the leaves striped with white, which appeared spontaneously in 1885 in the soil of a case of plants imported by the Botanic Garden of Brussels from Brazil.

CORDYLINTE INDIVISA, var. DONCETIANA, *L'illustration Horticole*, March 15th; a variegated variety of Belgian origin, the edges of the leaves marked with yellow.

TASCONIA PARRITE, *L'illustration Horticole*, March 15th. A handsome stove climber from Brazil with large orange flowers.

PRIMULA SINENSIS, var. EDWARD MORREN, *L'illustration Horticole*, March 15th; a variety with pale blue flowers; a novelty in Chinese Primroses.

ADANSONIA GREGORII, *Gardener's Chronicle*, April 28th; the Australian Baobab; one of the largest trees known.

DOUGLASIA LEVIGATA, *Gardener's Chronicle*, April 28th; a pretty little alpine plant of the Primrose family, from the mountains of north-western America. This genus commemorates the botanical labors of David Douglas, a Scotch botanical traveler, who discovered and introduced into cultivation some of the most important trees of Western America.

PHALÆNOPSIS SCHILLERIANA, *Gardener's Chronicle*, April 28th. "From an illustration from a photograph of plants in the collection of Fred. Scholes, Esq., of Brooklyn, who has been called the Partington of America, a compliment that is richly deserved, as our engraving undeniably proves. The two plants here depicted are fair representative examples (one being 3 feet in height), and only three years since were small pieces. Mr. Scholes is very liberal in the use of cow-manure in liquid form when his plants are making active growth. That he has practically demonstrated the efficacy of his treatment is proved by the luxuriance both in foliage and flowers of his *Phalænopsis*, one plant in his collection having no less than fourteen leaves from 8 to 15 inches long, and of remarkable substance. The plant carried three large branching spikes, and when in flower would be a marvel of beauty."

Notes.

Maple sugar was made this year in considerable quantities in California from the sap of the Broad-leaved Maple (*Acer macrophyllum*). The sugar is said to be of excellent flavor.

The annual meeting of the Society of American Florists in this city next August was to have been held in Tammany Hall. The burning of that building has somewhat embarrassed the local committee, but they have now secured the Fifth Avenue Theatre for that purpose.

Utricularia montana.—A splendid example of this showy plant is now flowering in the Orchid Houses occupied by Mr. I. Forstermann, of 50 Storm Ave., Jersey City. The plant mentioned has 26 stout spikes, on which are produced 100 large pure white blossoms of fine substance. This Bladderwort is sometimes classed with the Orchid family, to which genus it has no affinity. Its cultural requirements, however, are very similar, and it is invariably found in Orchid collections, where it thrives vigorously in a warm and very moist situation.

On the first of June Apples from New Zealand were on sale in San Francisco. According to so good an authority as the *Pacific Rural Press*, the fruit was not only shapely and handsomely colored, but firm and well-flavored. Apples from Victoria, are sold in the London market at from 2d. to 6d. each, and as the freight charges from the orchard to the seller are about 1½d. a pound, this leaves a good margin for profit to the grower in the Southern Hemisphere.

Retail Flower Markets.

NEW YORK, June 15th.

The supply of flowers this week has only been fair, but it has been sufficient to meet the demand. The decorations of halls and theatres for Commencement exercises have consisted of a few groups of foliage plants; Graduates' favors have been large loose bunches of flowers, more often than basket designs. Flowers from shrubs seem to grow in demand every year and have never brought as high a price as they now do. Syringa sells for \$1.00 a bunch of 18 large sprays, Weigela for 50 and 75 cts. a bunch. Snowballs are highly esteemed and cost \$1.00 a bunch. Hybrid Roses are smaller, but are of good quality, excepting Baroness Rothschild, which averages poor. All Hybrids cost 40 to 50 cts. each, the latter price holding for those selected. They are \$5.00 a dozen. Moss Roses cost 25 cts. a spray. Clusters of these with a few spikes of Mignonette are in demand for dinner favors. Genl. Jacqueminot Roses are small, but of rich colors, and bring \$1.50 a dozen. Brides, Catherine Mermets, Niphetos and Perles are also \$1.50 a dozen. Fine La France Roses cost \$2.00 a dozen. There are some handsome Orchids (Cattleyas) arriving which cost \$1.00 a flower. Pea blossoms are among the choice flowers added to bouquets and designs to give the last finish. They cost 50 cts. for a cluster of 18. Carnations cost 35 and 40 cts. a dozen. Pæonies range from 10 to 25 cts. each. The pink variety is in the largest request. Heliotrope is 50 cts. a bunch. Mignonette is poor and from 25 to 50 cts. a bunch. Field Daisies are very handsome and 15 cts. a dozen, and wild Buttercups cost 15 cts. a dozen. Gladioluses bring from 20 to 25 cts. a spike. Callas are scarce and 25 cts. each. Pansies cost 25 cts. a dozen. Lily-of-the-Valley is again coming in from green-houses.

PHILADELPHIA, June 15th.

Roses everywhere, and as a result there is a temporary glut in the market. It is only in Roses, however, that the over-supply is noticeable. Many other flowers are scarce, as for example, good Carnations, especially the white varieties. The crimson, scarlet and other colored varieties are fair in quality, and cost 25 cts. a dozen. Sweet Peas are more plentiful, and sell readily at from 25 to 50 cts. a dozen. Lily-of-the-Valley holds its own at \$1 a dozen. Mignonette and Heliotrope costs 25 cts. Hybrid Roses cost from \$2 to \$4 a dozen, according to quality and variety. Amongst out-door Roses there is a greater variety to select from than in the list of forcing sorts. Jean Liabaud and Louis Van Houtte are two favorites; the former is a velvety dark crimson, the latter is somewhat brighter and of very fine form. The dark Roses have not met with much favor in the winter for the past two seasons. American Beauty is still asked for, and sells at from \$3 to \$4 a dozen. Mermets, Bennetts and Brides are from \$1 to \$2 a dozen. Perles and Sunsets, 75 cts. to \$1.50. Bon Silenes and Gontiers are getting thin, and bring 50 cts. a dozen. Water Lilies are 75 cts. per dozen. Field Daisies are plentiful, and sell at 25 cts. a dozen. Single Dahlias, \$1 to \$1.50 a dozen. Cornflowers, 25 cts. a dozen. There is a steady demand for any choice good flower. Indeed, June is a better month for the flower trade than May, for new things like Sweet Peas, Miniature Sunflowers and the yellow Cornflowers keep coming into bloom, and are always salable.

BOSTON, June 15th.

The cut flower market has been heavily overstocked during the past week. Belated crops, intended for Decoration Day, but delayed by cold weather, have been coming in from every direction, and the wholesale dealers have been loaded down with surplus stock. Roses in all varieties, excepting the choice hybrids, are very abundant. Of choice hybrids there are none. Carnations are also very plenty in all the standard varieties, such as Anna Webb, Grace Wilder, Buttercup, Hinze's White, E. G. Hill and Allagatiere. There is still a small supply of Lily-of-the-Valley obtainable from Canada. After this is exhausted the green-house crop will begin to come in again, at increased prices, and will be in market as a regular supply all summer. The roots from which this is produced are kept over from last season in ice-houses, and are thus held in a dormant condition until required. White Gillflowers are abundant, and of best quality, very large and double. The choicer varieties of out-door flowers, such as Rhododendrons, Pæonies, Ghent Azaleas and Clematises, are used extensively in large baskets and decorations, and they help to make the florists' windows bright and attractive. Of Orchids a few *Odontoglossums* and Cattleyas (mainly *C. Mossia*) are in market. The demand for Lilies of all kinds is brisk, but very few are offered. Tea Roses bring 50 cts., but fancy sorts command from \$1 to \$2. Jacqueminots of rather inferior quality are held at \$3, and Hybrids are scarce at \$6. Carnations and Calendulas are 50 cts. a dozen. Stocks and Spiræa, 75 cts. Maidenhair Fern, 50 cts. Smilax, 50 cts. a string. Lilies-of-the-Valley cost \$1 a dozen, and will probably cost twice as much in a few days. Rhododendrons are \$5 a dozen; Ascension Lilies, \$2; Harris' Lilies, \$4, and a few Callas can be had for \$3.

Hardy Fruit Trees.

IN a recent number of the *Gardeners' Chronicle*, Mr. F. W. Burbidge advocates the introduction of fruits that are hardy in climates like that of the Volga region, where Apples, Cherries and Plums have been grown for a thousand years. He does not claim that these fruits would necessarily flourish in the moister climate of England, but he argues that if crossed with choice varieties of more tender constitution a new race might be hoped for which would have the fine flavor of one parent and the more vigorous habit of the other. The fruit growers in our north-western States have been experimenting in this direction with trees from the great central plain of Europe, where the conditions of climate more nearly resemble their own than do those of western Europe. But aside from this, there is ample encouragement for testing the fruit trees of other countries in the success which has followed the cultivation of the Japanese Persimmon and the Peen-to Peach, for example, in our southern States. No one can predict what advantage might be derived from crossing these with native species or garden varieties that are in cultivation here. Our best Raspberries and Grapes have been bred up from native species or by a mixture of native blood with that of introduced kinds.

The whole subject of improving fruit trees in hardiness by going back to the wild stock, or to forms that have become established by centuries of cultivation, is one that should engage the attention of our experiment stations. The fact that long years of work and study are required before any results are reached is all the more reason for beginning as soon as possible. As to the need of collecting and studying wild plants, Mr. Burbidge says:

In fruit growing, as in gardening generally, there is no standing still. We must either improve or we shall go back, and the best way to improve our native fruits will be to cross-breed with new blood in the shape of hardier kinds, from widely separated habitats and different soils. The Asiatic Grapevine did not succeed in America, but by inter-breeding it with native species a race of Grapes better suited to the cli-

mate has been obtained, and even the French vineyard cultivators have been glad to procure these American varieties to repair the ravages of the phylloxera during recent years.

One of the very best undertakings for our Royal Horticultural Society to undertake just now would be this task of collecting the wild species and cultivated variations of our hardy fruits, other than those now grown in England. It has always seemed to me, and doubtless to others also, a sad waste of time and capital to grow at Chiswick the ordinary kinds of Apples, Plums, Pears, Cherries, Grapes, etc., which are now to be seen in most nurseries and private gardens. The true work and business of a horticulture society is not with the old but with the new, and to be worthy of enlightened support the very fringe of progress must be lifted for us as it was lifted for our predecessors in the days of Lindley and Knight, Fortune, Douglas, Hartweg, and many others one need not name.

In conclusion, I venture to differ altogether from those who say that the days of collecting wild plants is passed or played out, and that the hybridizers can now carry on the work, and supply the collector's place to greater advantage. This view is the subtlest of all errors, viz., half a truth. There is room for the collector now as in the past, for the cultivator always, but the hybridist cannot with safety kick down a ladder on which he stands. The hybridizer may give us a few ephemeral forms of Orchids, Arads, Amaryllids, or florists' flowers, but what can he hope to do with our hardy fruits, vegetables, and grain-yielding grasses, when their wild prototypes are as yet un-introduced to our gardens? Looking broadly at the question, there is as much room for collectors now—more, in fact—than at any other time. The world of hardy flowers, now so popular, is practically untouched, and as I have said of the hardy fruits of northern Asia, we know practically nothing more than the late Karl Koch has told us in his books.

I believe the appointment by the Royal Horticultural Society of a really good collector, would be one of the most profitable investments the Society could make at the present time. Gardening is changing its ground now as it ever has done, and people generally are opening their eyes to the fact that the glass-house culture of a few stove plants or Orchids is a very small part of a great question. Gardening is creeping out into the fields, and every day the demand is greater for the best fruits, vegetables and flowers, that will grow in the open air.

The Sermon of the Flowers.

IF there are sermons in stones, there are more and clearer ones in the living works of nature. Just at this time of the year, for example, there is a lesson to be learned from the flowers which it would be well for us all to lay to heart and consistently put in practice. This is the lesson of free, persistent and painstaking giving.

Few persons are so parsimonious with the products of their gardens that they neglect to share them with their friends when chance suggests or some special occasion prompts. But, even to their friends, few give as persistently or as freely as they might. One is far too apt to think before giving whether his flowers are "good enough," and whether the recipient will "care about them." Such thoughts are as judicious as they are natural when the recipient is equally fortunate with the giver in the matter of gardens and hot-houses; but it is seldom realized how out of place they are when the friend in question can merely look at flowers over some one else's fence in summer and in winter must buy little bunches at big prices from a florist. Winter or summer even the refuse flowers of a rich man's garden would be gladly welcomed by more of his friends than he ventures to believe.

But it is not only to friends that nature bids us give—it is to the stranger, the wayfarer, the beggar. Here again it is too often doubted whether the gift would be really valued. Out in the country, where nature herself gives even to the poorest, perhaps it would not be. But in the city flowers are welcomed by every class as no other gift would be. Men may not always care for them, although almost always they do; but there will be found no exceptions among women and little children. Let a lady offer the flowers from her belt to the tired shop-girl behind the counter and she will carry about with her afterwards a memory of brightened eyes and smiling lips which will more than repay her for the sacrifice. Let her walk with

a bunch in her hands through one of the crowded streets in a poor quarter of the town—every child will clamor for a share of it, every forlorn and weary woman will eye it eagerly. Or let her take it to a hospital and see what pleasure a single blossom will give to a suffering soul. Nature's beautiful belief is indeed the right one—the cases are so rare that they need not be taken into account when a flower is not welcomed, no matter how humble it may be and no matter how devoid of sentiment the eye may seem to be which looks upon it. This is the right belief, and it would be well if we should try to express it as consistently and persistently as nature does.

As consistently and persistently, and, be it repeated, in as painstaking a way. Not merely when she is coaxed and flattered and things are made easy for her does nature give her flowers, but always and everywhere, under the most difficult conditions, with the loveliest patience and the most touching care and pains. This, to us of human-kind, is the greatest hindrance to giving; we do not mind parting with our treasures, but we do mind taking the trouble to dispose of them so that they will benefit others. We should be glad enough if our surplus could go by itself to tenement-house and hospital, but we are too busy or too careless to send it there. We would rather give money, for money can be more easily given. But money will not take the place of flowers, either in themselves or in that accompanying gift which makes half the excellence of their giving. He who gives flowers gives a bit of sentiment and sympathy too, and this is valued by the poor and suffering more than all beside. The very child who takes your blossom in the street takes it with a different smile from the one that greets your penny, for he knows or fancies it is given with a different thought.

In some of our large cities flower-missions have been established with headquarters where flowers may be sent and whence they will be distributed to those who need them most; and such missions ought to exist in every town, however small. But if they do not exist, a little trouble may well be taken to supply their place by individual effort. And we can all at least give freely as the chance may offer—to the child who brings home a parcel or peeps through the garden fence, to the workman plodding at nightfall past our garden to his own dreary home, to the shop-girl, to the poor needlewoman around the corner, to any one and every one whose steps cross our own. The gift cannot be too small to be worth giving—the human being can hardly be too callous to appreciate it or pass it on to some one else who will.

Some Eryngiums.

OUR Eryngiums have the reputation of being a hard genus, but since Mr. Rose and the writer have begun to study them in our work upon the North American Umbelliferae, we discover that the difficulty is not to be laid to the species themselves, but to the great confusion in naming them. Perhaps this is not to be wondered at, when one remembers the scattered condition of our literature regarding them. In the absence of the sharp contrasts which are brought out in a presentation of the species all together, collectors may well have become confused, and their errors have naturally become perpetuated. No genus of Umbellifers seems to have its species more sharply defined than *Eryngium*, and a few remarks about some southern and much confused forms may be helpful to botanists. In *Plante Lindheimeriana* Dr. Gray first unravels a bad tangle of synonymy, and clearly defines certain species which had before been perplexing, and which have been equally confused since. Our common *E. Virginianum* was first referred by Linnæus to his *E. aquaticum* as a variety, but was distinguished as a species and set up under its present name by Lamarck. Michaux then gave to the American forms of Linnæus' *E. aquaticum* the name of *E. yuccæfolium*, and referred to *E.*

aquaticum another plant which Elliott afterward described as *E. Virginianum*, but which was not the plant of Lamarck bearing that name. In *Pl. Lindh.*, 209, therefore, Dr. Gray, recognizing the establishment of *E. yuccæfolium*, Michx., and *E. Virginianum*, Lam., gave to Michaux's *E. aquaticum* and Elliott's *E. Virginianum* the name *E. præaltum*, and also separated from *E. Virginianum* another species which had been confused with it, and called it *E. Ravenellii*. As might be expected, *E. Virginianum*, *E. præaltum* and *E. Ravenellii* have been confused ever since.

E. Virginianum, Lam., is a slender plant, from one to three feet high, with lanceolate leaves, the lower on very long fistulous petioles, bracts as long as the head, bractlets with three spiny cusps (the middle one largest) and prominent, acuminate-cuspidate calyx-lobes, equalling or exceeding the bractlets. The species occurs along the margins of ponds and streams from New Jersey to Florida, and thence to Texas. Mr. Canby sends forms from Delaware, with bracts longer than the heads, but in every other respect they conform to this species.

E. præaltum, Gray, is a very stout plant, from four to six feet high, with radical leaves narrowly oblong (not unlike those of a *Rumex*), often two feet or more long, including the long petioles, bracts two or three times longer than the head, bractlets as in the last and longer than the calyx-lobes. It is found in tide swamps from North Carolina to Georgia. The so-called *E. præaltum* of Florida is another species.

E. Ravenellii, Gray, is slender, from one to three feet high, with linear, elongated, nearly terete (conduplicate) leaves, the lower ones twelve to eighteen inches long, bracts as long as the heads, bractlets with three strong and equal spiny cusps, short, mucronate calyx-lobes, and long, rigid styles. Formerly credited only to the wet Pine-barrens of South Carolina, with Ravenel as collector, it is now found to grow near Apalachicola, Florida, collected by Dr. Chapman. These Florida specimens Dr. Chapman took to be *E. Virginianum*, and it was from these, of course more or less modified by published descriptions, that he drew the characters of the *E. Virginianum* of his Manual.

Crawfordsville, Ind.

John M. Coulter.

Trees and Shrubs for a Trying Climate.

THE word "hardy" as commonly used is a relative term. With the prairie settlers of the north-west it means ability to endure the summer and winter extremes noted briefly in the article "Our Prairie Climate," in the issue of GARDEN AND FOREST for May 30th. Some of the essential characteristics of a truly "Iron-clad" plant here, are these:

(1) The foliage must be as perfect as that of the Duchess Apple, the Gakovska Pear, of *Populus Bolleana*, *Rosa rugosa* or of our native trees and shrubs that do well under cultivation on dry upland prairie. Critical observation under the microscope shows such leaves to be provided with extra rows of palisade cells, and a thick epidermis more or less protected by pubescence.

(2) The trees and plants with foliage adapted to great extremes of atmospheric heat and moisture are also protected by special structure of the outer bark, and all the parts of the flower are stronger; firmer and thicker, than those of plants developed in more equable climates. We may add that even the fruit of the true "Iron-clad" is protected by a thick epidermis and by more or less pubescence.

(3) The "Iron-clad" must be as fixed in its habit of growth as a Currant bush or a Hickory. The tree or shrub which can be lured into late growth by our warm, and often wet, autumns, will certainly be injured by our first norther.

(4) Our occasional warm south winds of winter and early spring will stimulate the tree or shrub from a climate dissimilar to ours into a feeble movement of sap, to be, perhaps, choked within twenty-four hours by zero weather. Our truly hardy tree must hibernate as perfectly as the

Duchess Apple, and I am glad to state that we have many trees and shrubs that are still better organized in this respect.

(5) The tree or shrub that defies our winter extremes, of from thirty to thirty-five degrees below zero, must have its new wood—even in the intercellular spaces—so perfectly stored with starch as to be incapable of being ruptured by freezing. A careful examination of the points of growth of the Silken-leaf Apple and of Bullock's Pippin will exhibit an unexpected difference in cell structure to the amateur in such work.

This too brief outline of the essentials of our hardy tree will naturally give the impression that our list of desirable trees and shrubs for the west must be short. But thanks to a rich natural flora, and direct and indirect introductions from old world climates of plants, not unlike our own, we already have a large and varied list to select from.

Some of the varieties and species which seem worthy of trial over large areas of our country will be noticed freely in another communication.

Ames, Iowa.

J. L. Budd.

Alexander Pope and the Gardener's Art.

IN most men's minds the name of Alexander Pope is a synonym for artificiality in art. There is, of course, a further kind of artificiality than Pope's—the kind which is not art at all. But among genuine artists in verse, he stands as the representative of formality, self-consciousness, rule and measure, of high polish, studied grace and well-balanced, rigorously calculated charm; as the very antithesis of all that is meant by the words natural, spontaneous, free and fresh. Narrowly considered as a poet for his manner of speech, the verdict is a true one. But there was more to Pope than this poetry, and there is more even in his poetry than its form. And it is a disappointment to find that so acute a critic, and so sympathetic a student of the eighteenth century, as Mr. Austin Dobson, fails to make these facts as clear as they ought to be made in his article on the poet, recently published in *Scribner's Magazine*.

It is but fair to say, however, that Mr. Dobson is not alone in his failure. So far as I have read, no biographer of Pope has recognized the service which he rendered the world in a branch of art which was not his own. None of them has explained that to this poet, whom we call the apostle of formality, England is more indebted, perhaps, than to any other single man, for the development of the "natural style" of gardening. Historians of the gardener's art have been more clear-sighted, but the attitude of his professed biographers is typified by that of Dyce, who says, "Though his writings exhibit incidental glimpses of rural nature, he appears to have had no passionate sense of her beauties; he had more pleasure in describing those external objects which are artificial than those which are natural. . . . In his *Windsor Forest*, which gave him an opportunity of presenting to us distinct and peculiar landscapes, his descriptions of scenery are general and without individuality." This is one of those verdicts which are true in the letter, but false in the impression they give. It is true that Pope's *Windsor Forest* shows us no such rural pictures as a modern writer would paint, is peopled with nymphs and dryads, and breathes in general the pseudo-classic spirit of the age; and it is likewise true, as Mr. Dobson says, that it "is cold and conventional to the modern reader." But had Pope really "looked at nature with the unpurged eyes of his generation"—Mr. Dobson's words again—he would hardly have written of *Windsor Forest* at all, and his poem would certainly have lacked those occasional breaths of freshness and that underlying strain of sincere feeling for nature's sincerest self, which even to the modern reader (if he can read a little deeply) redeem its coldness and artificiality of form. So, too, while it is true that

Pope can 'have had no "passionate" feeling for rural nature, we must remember that his life, except in its very early years, was passed in the cockneydom of Queen Anne's reign—in London itself, or beside the villa-ed Thames; and that it was a marked peculiarity then and there to have any feeling for rural nature at all. Again, it is true that, as a rule, he describes artificial, not natural, scenes; but artificial is a word of wide significance, and to accept it in this connection in its most pronounced significance, is wholly to misconceive of Pope. The scenes which he loved best were artificial, in the sense of having been created or altered by art. But they were not artificial in the sense of being formal. And this fact marks him off distinctly from the mass of his contemporaries—gives him a place in history as the apostle of a new art whose tastes and ideals were far ahead of those of his generation. If we study the little plan of his famous garden at Twickenham (published with Mr. Dobson's article), we see that, although some parts are formally designed, there are others in which a natural looking arrangement has been made; and all the descriptions of the place which have come down to us make clear its unlikeness in this respect to the typical garden of the time. Moreover, Pope's titles to honor, as an advocate of natural gardening, do not rest solely on his Twickenham experiment, or on the sentiments implied in his *Windsor Forest*. A paper on *Verdant Sculpture*, which he published early in life in the *Guardian*, is known to have worked a revolution in English practice—to have scotched, if not instantly killed, the practice of clipping trees into formal shapes. Kent, at first a painter, and then the earliest of English landscape gardeners—in the true sense of the word—was deeply influenced by Pope; and the famous Epistle to the Earl of Burlington, *On the Use of Riches*, might serve to-day as a text-book of aphorisms for the landscape gardener's instruction. It seems strange that Mr. Dobson did not dwell upon the passages in this poem which refer to the gardener's art—they would have served him for the establishing of so pretty an antithesis between Pope the formal poet and Pope the advocate of informality in another art. Might one not expect that Versailles would be his ideal, and the long drawn aisle of verdure, the square walled pool, and the marble terrace his synonyms for beauty out-of-doors? No; what he says is:

To plant, to build, whatever you intend,
To rear the column, or the arch to bend,
To swell the terrace, or to sink the grot,
In all, let Nature never be forgot. . . .
He gains all points who pleasingly confounds,
Surprises, varies and conceals the bounds.
Consult the genius of the place in all;
That helps the waters or to rise or fall;
Or helps th' ambitious hill the heavens to scale,
Or scoops in circling theatres the vale;
Calls in the country, catches opening glades;
Joins willing woods, and varies shades from shades;
Now breaks, or now directs, th' intending lines;
Paints as you plant and as you work designs.
Still follow sense, of every art the soul;
Parts answering parts shall slide into a whole,
Spontaneous beauties all around advance,
Start e'en from difficulty, strike from chance. . . .

And when he desires to say what should *not* be done, these are his words:

His gardens next your admiration call;
On every side you look, behold, the wall!
No pleasing intricacies intervene,
No artful wildness to perplex the scene;
Grove nods at grove, each alley has a brother,
And half the platform just reflects the other. . . .

Thus did Pope preach of gardening, and thus, according to his lights and opportunities, he tried to practice it. When Mr. Dobson, in the charming poem which follows the prose article, says of him, that "his Nature" was "a Parterre," the words are used in a metaphorical sense, as illustrative of his literary style; but even thus, it hurts us a

little to read them. It seems a lapse from perfect justice—or, should I say, from perfect taste?—to speak of parterres, even metaphorical, verbal parterres, in connection with the man who did so much to free gardening from the fetters of formality, to “call in the country,” and vary “shade from shade.”

I would not be understood as implying that Pope fought quite alone his crusade against formality in gardening. A hundred years before his time Bacon preached the virtues of a more sympathetic treatment of nature, and Milton sang the charms of a great natural garden. And in his own generation, Addison fought valiantly at his side. But it was only in the century of Addison and Pope that words bore fruit in actual deeds; and it is doubtful whether any single influence was as potent as Pope's in the matter. If we cannot quote the last line of his *Windsor Forest*,

First in these fields I sung the sylvan strains,

and make it apply with literal truth to gardening in England, we can say, at least, that he sang the sylvan strain more convincingly than had any one before him.

A date or two in conclusion may be of interest. Addison's *Description of a Garden in the Natural Style* was published in 1712, Pope's *Verdant Sculpture* in 1713, and his *Epistle to Lord Burlington* in 1731, while the first professional treatise on the natural style of gardening—Whateley's—did not appear until 1770.

M. G. van Rensselaer.

A Well Planted Village Street.

IT is not always that a village street makes a pleasing picture, but the impulse of any artist who might chance for the first time to face the leafy vista from which our illustration (page 209) is taken would be to make a sketch of it. And yet the elements of this picture are of the simplest and most natural character. We can conceive of a street which would be attractive on account of the well planted and well kept lawns on either side, with road borders straight and trim. But here the lawns form no feature of importance, and the problem of how much space shall be devoted to wheelway and foot-path is left to settle itself in the most practical and natural way, as the feet and wheels themselves may dictate. The paths are therefore laid just where they are most convenient, and certainly the flowing curves which mark the boundary between grass and gravel are more beautiful than any straight line could be, while they do not demand the frequent labor of cutting the sod and raking over the road-way, which are necessary when a formal border is neatly kept. The Dandelions in the grass bear witness that the lawn-mower is not used to destroy all the wild flowers, and these in their season add to the natural and rural charm of the street. The brightness of a bit of sky seen beneath the overarching limbs of trees which frame it in always adds a tone of cheerfulness to such a vista, and the sunshine which here sifts through the foliage on either hand forbids any thought of gloominess in the dwellings which a too dense shade invariably suggests. Altogether, this street picture has a balance and harmony which would not probably characterize one composed of various border plantations made in accordance with the individual tastes of different land-owners, and it is, therefore, pleasantly suggestive of a community of interest in the street and its beauty—a suggestion emphasized by the public well which stands for neighborliness and sociability.

It would not be wise nor practicable for any other town or village to imitate this example in detail. But no serious offense against the canons of good taste can be committed where a village street is so planted that it makes a complete picture—a picture as peaceful and natural as the one here presented, and with such unity of motive that no contradictions or incongruities are apparent.

Foreign Correspondence.

Notes on New Orchids.

SOME beautiful novelties in Orchids have been shown during the past week or two at the Royal Horticultural Society's exhibitions. One has excited unusual interest, being a new *Cypripedium*, a genus which is now so fashionable. It is a very near relative of the now well-known *C. Godefroya*, which was introduced a few years ago from Cochin China, and is called *C. bellatulum*.* It appears to be a free bloomer, as the plants exhibited on Tuesday last had several spikes, although they had not been out of the packing-case many days. Messrs. Low, the well-known Orchid importers at Clifton, are the introducers, and it is thought that they have made a hit in importing the plant in such health. All orchidists know and admire *C. Godefroya*, and the new plant being so much superior, it will, without doubt, prove popular.

Disa racemosa (*D. secunda*) was also shown for the first time on Tuesday. It is not a new plant to botanists, having been discovered many years ago in south Africa, but this is the first time it has flowered in cultivation. In growth and foliage it can hardly be distinguished from *Disa grandiflora*—the Flower of the Gods—but in flower it is very different. It has erect spikes rising about eighteen inches high, and on the upper parts of these are loosely arranged the flowers, each being about two inches across; in shape resembling those of *D. grandiflora*, but in color of a deep rose-pink, or, as some describe it, rosy-crimson, a color pleasing to every one and not common among Orchids. The plant is as easily grown as *D. grandiflora*, requiring an atmosphere cool and moist and partial shade. Some fine plants of it are now in flower in the Royal Gardens, Kew, the plants having been collected in south Africa by the assistant curator, Mr. Watson, when traveling in that region. No doubt the enterprising collectors of America will soon have it, as it is already in the trade.

A grand new *Cattleya*, a variety of *C. Mendelli*, was the admiration of all who visited the Exhibition of the Royal Horticultural Society in the Temple Gardens. This *Cattleya* was called *Rothschildiana*, in compliment to the great patron of Orchids. It is impossible to describe the distinguishing points of the flower, but it is one of the largest flowered forms of *C. Mendelli* I have ever seen, with broader sepals and a very ample lip with a lobe almost circular. The color, however, was its greatest charm, being so soft and delicate, the sepals being of one tint, the lip of another, and exquisitely frilled and margined with the deepest tint of all. It came from the St. Albans' Orchid nursery.

A very remarkable Orchid shown also at the Temple exhibition was *Lissochilus giganteus*. Like other species of *Lissochilus*, it is terrestrial, has long, broad, plicate foliage, and a flower stem towering six or eight feet in height, carrying numbers of large and curiously shaped flowers of a rosy-pink color. It is a singularly noble Orchid, but hardly one that everybody would care to cultivate, as such a giant takes up too much room. It was in the superb collection shown by Sir Trevor Lawrence. In that from Baron Schroeder, who owns one of the richest Orchid collections in Europe, were also some very choice things. I single out a few that struck me as worthy of note, and none more so than the snow-white *Ærides Williamsii*, which some say is the albino of *Æ. Fieldingi*, the Fox-brush Orchid. Though not absolutely new, it is so rare that most orchidists, even old, experienced men, had never seen it. A new *Scuticaria* called *Keyseriana*, after the Lord Mayor of London, who visited the exhibition, came from Messrs. Sander & Co. It has affinity with *S. Steelii*, but its flowers are larger, more heavily and richly blotched and barred, and, altogether, it is a finer flower.

*A brief description of this Orchid was given in a late number of this journal.—Ed.

The first Hybrid Epidendrum that is known to have been raised and flowered under cultivation was shown by Messrs. Veitch last Tuesday. It is named *E. O'Brienianum*, after the well-known orchidist, Mr. James O'Brien. This is a cross between the orange-scarlet flowered *E. radicans* (also known as *E. rhizophorum*) and the pink *E. evectum*. The hybrid shows the features of both parents in its flowers, both in form and color, the latter being of a kind of magenta-purple, just the tint, in fact, you would get by mixing vermilion-orange and crimson-lake on a palette. This cross, though not remarkable from the standpoint of beauty, is looked upon as important, as it may lead to really valuable results in the large genus Epidendrum. Two other hybrids were shown by Messrs. Veitch, one of which was said to be a cross between *Anguloa Ruckeri* and *A. Clowesii*. The flowers of the hybrid are like those of *A. eburnea*, being white, copiously freckled with pale red. One would have thought that the yellow of one and the blood-red of the other flower would have produced a cross quite different from the one

species, this plant (See Fig. 38, page 211), when grown, has no produced leaves, the stem leaves being all short, and the lowermost tipped with long, rigid, thread-like appendages which are cruelly barbed. The flower-bracts are not conspicuous, but the flowers, which are comparatively large, are of a light red color, and droop gracefully upon the slender pedicels. S. W.

Plant Notes.

Iris Korolkowi.

THIS is a beautiful new Iris, original in form and outline, showy and strange in colors. It was discovered and imported from Turkestan some twelve years ago and is one of the hardiest of its race. The flowers appear in May, and with the type and one variety, the ground color of falls and standards is a peculiar grayish-white, beautifully netted with olive and coffee-brown streaks; in some other varieties the ground color has a

Main Street, Kingston, Rhode Island.—See page 208.

shown, which was named *A. intermedia*. Another hybrid Orchid was a cross between *Dendrobium Dalhousieanum* and *D. Huttonii*. Here again the result is disappointing, though one could trace the feature of both parents in the flowers of the new comer, which is oppressed with the unpronounceable name of *D. porphyrogastrum*. It is obviously premature to speak of the merits of hybrid Orchids the first season of flowering.

London, May 24th.

W. Goldring.

New or Little Known Plants.

Pitcairnia Palmeri.*

THIS is one of the smallest species of the genus, and was discovered with the one previously figured, by Dr. E. Palmer, growing abundantly in the crevices of rocks in the mountains of Jalisco, Mexico. Unlike the former

*P. PALMERI, Watson, Proc. Am. Acad., xxii. 456. Acaulescent, somewhat furfuraceous throughout, the basal bracts ending in barbed, filiform appendages; leaves of sterile shoots very narrowly linear, entire, sparsely villous; those of the flowering stem bract-like and very narrowly attenuate; floral bracts, narrow, shorter than the reflexed pedicels; petals, light red, 1½ inches long, three times longer than the narrow, acuminate sepals; stamens and style included.

flush of purple and in one variety it is deep purple; the netting of all these is simply deeper in color. It takes to any soil, but prefers a loamy one. It enjoys a long, hard winter and a bright spring.

Max Leichlin.

Baden-Baden.

Calypso borealis.—The flowering season of this little Orchid is just over, and those who have had the pleasure of seeing it in its native habitat may consider themselves fortunate. The peculiar shape of its flower, the variety of delicate colors—pink, purple and white—and the single dark green leaf, make it a favorite among lovers of wild flowers, but to fully appreciate it, one must gather it in its natural home. It usually grows in dark cedar swamps among the largest and oldest Arbor Vitæ trees. Like *Aplectrum hyemale* and *Tipularia discolor*, it sends up its leaf and flower-bud in autumn, and in spring it is ready to start into growth as soon as the snow and frost disappear. Its height is usually three to five inches. After flowering it dies down to the bulb and remains in this until late in autumn. The bulb is quite small and the leaf so inconspicuous, that it is difficult to find the plant except when in flower. Coming so early in the season and being such a rare species, it is seen by only a few. In some portions of northern Vermont it is much more abundant than in the mid-

dle parts, and is quite rare, if it grows at all, in the southern part of the state. For this reason I am inclined to believe that in eastern Canada, where the *Arbor Vita* attains a much larger growth, it is quite common. It grows very abundantly in portions of Oregon and Washington Territory.

F. H. Horsford.

Pentstemon barbatus, Nutt., var. *Wislizeni*, Gray.—“Next in beauty comes the bright-flowered *Pentstemon coccineus*,” continues Engelmann in his report on the collection of Wislizenus; yet he could only judge of its beauty from dried specimens, with colors more or less changed or dimmed in drying, or from the accounts of his friend. Seen growing in its native haunts—near streams of wooded ravines of the Cordilleras—with slender, straight stems two or three feet high, clean, glaucous green leaves, and flowers in color between scarlet and crimson, scattered on filiform pedicels, it is, indeed, a graceful and lovely plant. In recent years Dr. Gray has referred it to *Pentstemon barbatus* of Nuttall, and given it a varietal name to commemorate its adventurous discoverer. C. G. Pringle.

Variations in *Viola pedata*.—There is a hillside near German-town famous for its great abundance of this beautiful flower. When a thousand plants are in full flower, as they were, a few weeks ago, a more charming sight could hardly be desired. While wandering among them I came upon four plants with flowers white as snow, a single plant with a distinct, dark eye, several with very light blue flowers, and others of a color almost identical with that of *Houstonia carulea*.

Joseph Meehan.

Cultural Department.

Poppies.

JUST now Oriental Poppies are in full bloom here and a brilliant display they make. Last year they were in their finest condition between May 26th and June 5th, but this season they, together with most other garden plants, are a week to ten days later in blooming. These Oriental Poppies are hardy, herbaceous perennials of the easiest possible cultivation, and long-lived, and they spread and multiply considerably from underground shoots. They are grown here in a mass several yards square on a warm, dry, sandy bank, where the ground, although naturally poor, is well enriched by surface manuring; the roots can penetrate as deep as they are inclined in the open soil—often four feet or more. Here they flourish and bloom most plentifully. But where the ground is better and the position more sheltered by neighboring shrubs, the Poppies are finer and less apt to be scorched by warm sunshine. When the plants have done blooming they are cut over and *Eschscholtzia Californica* is sown among them; this soon covers the ground and blooms through September and October.

The European Corn Poppy (*Papaver Rhæas*) is easily naturalized on sandy banks and in bulb beds. Here they grow at will and sow themselves. The Hyacinths, Narcissus and Tulips come up and blossom in April and May, and before they are out of bloom the Corn Poppies have covered the ground and begin blooming about the end of May. After their flowering season is over they are cleared away, as they are only annual, the bulbs are lifted, the ground forked over, and the bed planted at once with French Marigolds, Zinnias, Gaillardias, Vincas, Pelargoniums, or some other sun-loving plants. These are removed in October and bulbs are then set out for spring flowering. Seeds enough have fallen from the Poppies upon the ground for next year's crop, and they come up all over the surface like a thick crop of weeds.

Of the large double-flowered annual Poppies known as Ranunculus-flowered and Pæonia-flowered, we have a bed sixteen yards by twelve yards on a warm slope. The seeds were sown early in April, broadcast, raked in and rolled, and a sprinkling of *Eschscholtzia* seed was also sown at the same time along the outer edge of the bed. The *Eschscholtzia* is now in bloom but the Poppies will not flower till the first of July, when they always make a gorgeous blaze. But they do not last long—hardly three weeks. When they are done blooming the ground is cleared and forked and Marigolds or Zinnias are planted for autumn blooming. It is not worth while to wait for these Poppies to sow their own seed, as it costs but a trifle and it is better to clear off the plants before they ripen seed than to delay the next crop.

Such beautiful Poppies as Peacock, Danebrog and Mephisto can be raised from seeds grown in the green-house in March, and they should be grown along in pots till the first of May and then planted out in the garden. Treated in

this way, the Peacock Poppies are now in bloom; the others are not. But these may be sown out-of-doors in spring in the same way as the Pæonia-flowered Poppy, or they may be sown in the fall like Corn Poppies. In both cases they will grow and bloom well.

In a cold-frame the beautiful Alpine Poppies (*P. nudicaule*) have bloomed since April. They are hardy perennials, but the best practice is to treat them as annuals or biennials. They are of dwarf habit, and some are white, others bright yellow, and others orange; and when growing near each other the yellow and orange varieties mix together, and we often get yellow blossoms that are striped with orange and orange blossoms striped with yellow. These are lovely and appropriate plants for the rock-garden and they should be grown where water will not lodge about them, or hot south-west sunshine strike them in summer. If you grow them in the rockery let them naturalize themselves there; this they will soon do, as they scatter their seeds and seedlings come up all about them. Some young plants, raised from seed sown in the green-house last February, and planted out early in May, are now in bloom.

William Falconer.

Glen Cove, N. Y.

Bedding Plants for Spring.—The expensive fashion of “bedding out” is gradually losing favor, especially in England. It survives here perhaps because the number of plants available for summer bedding in this country is considerable, and success is comparatively easy. With spring bedding this is not so. The English system has been generally followed, but the difficulty here is in using the variety of plants used there. Wall-flowers, Aubrietias and *Saponaria Calabrica* cannot be used at all. Hybrid Oxlips wilt, and rapidly fade after the first spell of warm, bright weather. *Arabis albidia* and *Myosotis sylvatica* quickly run to seed, and *Myosotis dissitiflora*, which is a perennial and not an annual, and by far the better kind, is later in flower here because it must make new flowering shoots; those formed the previous fall, and which should flower early the next spring, being invariably killed back to the root-stock during winter. Perhaps seed sown or cuttings taken in August and wintered over in a frame would give early flowers; but I have never seen this tried. *Silene pendula compacta* does well if sown in July or August and kept over in a protected frame; it comes in well, and is charming when planted as a groundwork for yellow Tulips. As a groundwork for scarlet Tulips nothing is more beautiful than a bed of Pansies, especially since the great improvement in the French varieties of these plants. They have also the advantage of being easily and cheaply raised.

In addition to the above named, many-early flowering American plants are useful for spring bedding. It will possibly be regarded as an expensive innovation to suggest a bed of *Trillium grandiflorum*. But the expense would not be greater than the cost of many pieces of summer bedding, while the beauty would be infinitely greater. Why not have a bed of *Viola pedata*, even though the plant is common in some localities? The Dog-tooth Violet would make a handsome spring bed, and could be as easily followed by summer bedding as Tulips, though the same could not be urged in favor of the Trillium. The beautiful varieties of Moss Pinks (*Phlox subulata*) have proved admirable spring bedding plants. The varieties best adapted to this purpose are Nivalis, white; Atropurpurea, purple; Vivid, bright rose; and Model, light rose. It takes considerable time to work up a stock of these, and in order to keep their foliage green they should be protected in winter.

T. D. Hatfield.

Wellesley, Mass.

Primula officinalis.—Several patches of the English Cowslip are now in full bloom on a north hillside. These were planted six years ago and have had no protection whatever other than snow. The soil is a very poor clay loam. Our winters are very severe, the thermometer often registering more than 20° below zero. On the same hillside, though in better soil, are some clumps of *Scilla nutans* (Bluebells), also of *S. campanulata* in var. These have proved to be perfectly hardy and make quite an addition to our early summer flowers. We grow a large number of these Scillas in pots for house decoration, and now that we are sure of their being hardy, shall plant out all our surplus corms. *Narcissus Polyanthus* is hardy here, although they do not flower well, but *N. poeticus*, both double and single, bloom freely, and I have never seen better or larger flowers of the double variety, than those now on the hillside and which have come up through the sod. Jonquils are equally hardy and flower freely. *Erythronium grandiflorum albiflorum* (vide p. 177) is hardy here, having withstood several severe winters, and flowers annually. A small bed of *Iris xiphoides* has wintered well without the

least protection. If this should prove hardy it will be a grand acquisition.

Kenwood, N. Y., June 6th.

F. Goldring.

Spring Beauty.—This pretty little flower (*Claytonia Virginiana*), mentioned on page 177, grows abundantly in some parts of the woods near here. The largest group occurs near the edge of a swamp in a thick wood of Beech, Chestnut, and other trees. The hollow of the swamp is filled with *Symplocarpus foetidus*,

and begins to fade about the first of June. By the middle of June they have withered and disappeared, and without a close search their presence would be unnoticed. They come up, bloom and complete their growth while the woods are moderately open—that is, before the leaves have come upon the trees. In Central Park this plant is naturalized in the grass under the trees on a moist bank. As a garden plant it is of the easiest cultivation and in the rockery it survives year after year. The wild tubers can be gathered and planted in the garden or a stock of plants may be obtained from seed.

Glen Cove, N. Y.

Orchid Notes.

Orchids in Bloom.—The collection of De Witt S. Smith, Esq., of Lee, Massachusetts, comprises many choice specimens of this genus now in bloom. Conspicuous among them is a group of *Cypripediums* in splendid health, their broad, stout, green foliage, and large, well-formed blossoms, indicating intelligent treatment. The *Cypripedium* house is a span roof structure, having a centre stage forty feet long by eight feet wide, with side stages of the same length. Amongst the most notable in bloom is a very distinct variety of *C. Lawrenceanum*, the purple lines on the broad dorsal sepals being intermixed with numerous small, dark purple spots. The petals stand boldly outwards, the pouch being very narrow. A magnificent example of *C. Dayanum* named Smith's variety showed a flower twice the size of the common *C. Dayanum*. Another remarkable variety observed is a form of *C. Godefroya*, with broad, round petals, the ground color of which is pure white and the markings of the darkest purple. The foliage of this variety is clear green on the under side, while in the ordinary form it is of a dark chocolate color. *C. niveum* is represented by more than twenty plants in bloom, the stout spikes being unusually tall, and, in many instances, twin-flowered, forming a delightful contrast with its handsome mottled foliage. Mr. Norman, the gardener here, places the plants of the latter species, shortly before blooming, into a little more heat, to enable the spikes to attain a greater length, that the blossoms may be seen to a better advantage. Specimens of *C. grande*, *C. ciliolare*, *C. Dominii*, *C. Warneri*, *C. hirsutissimum*, are in superb condition, together with a very fine variety of *C. barbatum*, the centre of the flower being of a blackish purple and the petals tipped with light chocolate. *C. vernixium*, *C. Dauthieri*, *C. Hookera*, *C. concolor* *Regnierii*, specimens of *C. Morgana*, *C. cardinale*, are growing rapidly here, with a dozen plants of *C. Spicerianum* with fully fifty growths each. The *Cattleyas* are very showy, the flowers being unusually large and high colored. A plant of *C. Mossia* bore nine flowers on three spikes of extraordinary size, each measuring fully ten inches across, with petals four and one-half inches wide, lip three and one-half inches broad, and of a beautiful bright rose color. Large specimens of *C. Mendelii*, *C. Lawrenceana*, *C. Skinneri*, and a well-flowered plant of *Oncidium Jonesianum*, with a branching spike, formed the most attractive group in the *Cattleya* house. A fine group of *Dendrobium Pearcei* was also in flower, its pure white blossoms having remained nearly three months in bloom. Several examples of *Vanda suavis* were looking in excellent health, together with a quantity in bloom of the Butterfly Orchid, *Oncidium Kramerii*.

A. D.

Cattleya Sanderiana.—A magnificent variety of this fine Orchid is in bloom, with a four-flowered spike. The petals measure nine and one-half inches across and are a uniform deep rose. The lip, which is three inches across, is a beautiful magenta purple, which is brightened by the bold, yellow eye-like blotches characteristic of this species. This *Cattleya* is one of the earliest to start into growth, and grows very rapidly, flowering within two months from starting. It requires heat and a liberal supply of water until the bulbs are thoroughly matured, after which it should be taken out of the growing house and rested in a cool airy place; otherwise it will start a second growth which will weaken the plant. This is a somewhat new *Cattleya*, native of Colombia; but this species as well as *C. Imperialis*, are only geographical forms of *C. Gigas*, or, more properly, *C. Warszewiczii*.

Chysis Chelsonii.—This handsome Orchid is now bearing two spikes of 28 flowers. It is a hybrid between *C. lavis* and *C. Limninghei*, in growth resembling the former, but like the majority of artificial hybrids, it is much stronger than either of its parents, and a very free grower. It is an Orchid that objects to have its roots confined in a pot and should be allowed to ramble at will. It must be kept well supplied with water, and when forming its bulbs weak liquid manure may be given nearly every day. It requires strong heat to form large bulbs,

Fig. 38.—*Pitcairnia Palmeri*.—See page 209.

Veratrum viride, and the like, and the moist sides with broad stretches of Dog's-tooth Violet and Spring Beauty. In the wet-fish ground the tubers lie on or at the surface and are merely covered with a layer of fallen forest leaves; further up on the dry ground the tubers are buried in the earth from half an inch to three inches deep. From each tuber—according to its size—one shoot or a bundle of shoots—each containing a pair of opposite leaves and raceme of flowers—is produced. This Spring Beauty appears above ground about the first of May, is in bloom and full growth about the 20th of the same month

and though it should be kept comparatively dry when at rest, a warm house in winter suits it best.

Lælia flammea is a showy and rare hybrid raised from *L. cinnabarina* and *L. Pilcheri*, itself a hybrid. It somewhat resembles the former in growth, and the flowers are much in the way of *L. harpophylla*. Our plants are growing freely with the usual *Cattleya* treatment.

Kenwood, N. Y., June 8th.

F. Goldring.

Notes from the Arnold Arboretum.

FRAGRANT flowered Maples are not common; for this peculiarity, and for the great beauty of its brilliant autumn foliage, the variety of the well known Tartarian Maple which is found in the valley of the Amoor River in Manchuria, is well worth general cultivation. It is the *Acer Ginnala*, or, as M. Maximowicz now considers it, the *Acer Tartaricum* var. *Ginnala*—a small, bushy tree, attaining here a height of 15 to 25 feet, with bright green, smooth and shining, ovate, serrate leaves, incisedly trilobed, the terminal lobe longly acuminate. The yellow, long pediceled, small flowers are deliciously fragrant; they are produced in rather loose erect axillary racemes. The Manchurian plant differs from the typical *Acer Tartaricum* in its thinner and less coriaceous, narrower and more deeply lobed leaves, in which the middle lobe is much longer and narrower. The Manchurian Maple is a perfectly hardy, fast growing plant, whose autumn foliage rivals the Sugar Maple in the splendor of its orange and scarlet tints. It is very easily raised from seed, which has been produced here in great abundance for several years.

The English Hawthorn is not a very satisfactory tree in this climate, where the summer sun is too hot for it, scorching the leaves, which are preyed upon, too, by several species of fungus; so that it is not unusual to see plants almost entirely destitute of foliage by the end of August. The beauty and the abundance of the flowers, however, must compensate to a certain extent for this drawback to the English Hawthorn here, and of the innumerable varieties known in European nurseries, none is more vigorous or more satisfactory than a double-flowered scarlet variety, which originated in England not many years ago, and which is known as Paul's Double Scarlet Thorn. The rather small clusters of bright scarlet flowers are produced in the greatest profusion.

The American Crab Apple, *Pyrus coronaria*, is less frequently seen in gardens than the Japanese and Siberian apples. It is, however, an ornamental tree of very considerable value and beauty, and it has the great merit of coming into flower ten or twelve days after all the other apples have shed their petals. The American Crab Apple is a small bushy tree, twenty or thirty feet high, pretty generally distributed through the Appalachian forests from Ontario to Alabama, although not extending into New England and eastern New York. It has serrate or lobed, ovate, somewhat cordate leaves, and broad cymes of pale pink or rose colored flowers, which are nearly two inches across. The orange fruit, flushed with bright scarlet when fully ripe, is an inch or an inch and a half in diameter; it hangs on long slender stalks, and like the flowers is deliciously fragrant; it is sometimes used for preserving. This tree loaded with fruit in the autumn is hardly less ornamental than at this season of the year.

The earliest of the Spindle-trees (*Euonymus*) to bloom is an east Asian species, *E. alatus*, a widely distributed Japanese and Manchurian plant, remarkable for the wide, corky wings of its branches. It is now covered with small yellow-green flowers in loose, generally three-flowered cymes. The fruit is much less conspicuous than that of many other species of this genus, and its greatest merit is the beauty of the peculiar rose color of its autumn foliage, quite unlike that assumed by any American plant, or by any other Japanese plant in the collection. The peculiar corky formation of the branches, which is hardly developed at all upon one variety here, is also interesting. Varieties differ very considerably, in the time of flowering, and in the number of the flowers in their cymes. *Euonymus alatus* is very hardy here, soon developing into a handsome compact specimen four or five feet high. It is figured by Regel in his "*Flora Ussuriensis*," t. 7. The prostrate form of the Strawberry Bush (*Euonymus Americanus*, var. *obovatus*), is in bloom before the other American species. This is a useful subject for the borders of shrubberies and for other positions where it is desirable to connect the turf with higher plants, or to plant as undergrowth under trees. It is seldom used in gardens, however, although by no means a rare plant in much of the regions south of New York and east of the Mississippi River. It has long trailing branches which root freely, thin, dull, dark green, obovate leaves, erect flower-stems one or

two feet high, small greenish purple flowers and rather conspicuous warty crimson fruit with a scarlet aril.

Rhamnus alnifolius is another dwarf American shrub which, although possessing very considerable merit as an ornamental plant, in its compact habit and handsome foliage, is rarely found in gardens. It is a native of northern swamps, but takes readily to cultivation, soon forming dense, wide-spreading clusters of erect stems, a foot and a half or two feet high, clothed with pale yellow-green, ovate, acute, sharply serrate leaves, with prominent veins. The small yellow flowers and the black fruit are not conspicuous. It is now in flower.

Pyrus (Aronia) arbutifolia, the Chokeberry, is now in flower, and is exceedingly ornamental both in foliage and in flower. There are two distinct forms of this plant, the var. *erythrocarpa*, with narrow leaves, very woolly on the lower side, as well as the cyme, and purple-red or scarlet fruit, which remains upon the branches late into the winter; and the var. *melanocarpa*, which is nearly smooth and produces black fruit. *Pyrus arbutifolia* is a common shrub throughout the eastern part of the Continent from Newfoundland to Louisiana, with slender branching stems two to ten feet high, covered with grayish-brown bark. The leaves are an inch or more long, lance-oblong, oval or obovate, tapering at the base, sharply serrate, pale and often downy on the under side when young, dark green and shining above, the mid-rib glandular along the upper side. The handsome white flowers, often tinged with purple, and with conspicuous purple or brown anthers, are produced in compound downy corymbs; they are nearly an inch across when expanded. Those in the red-fruited variety, which is most common in the South, are considerably smaller and appear here fully a week later. The fruit is a five-celled pome, the size of a blueberry, rather dry, but sweetish to the taste. The common northern smooth forms, with purple or black fruit, vary considerably in the shape of the leaves and in the size and color of the flowers. Some of these forms are exceedingly ornamental when in flower, and the variability which this plant displays naturally, makes it not improbable that, as an ornamental plant, it might be greatly improved through cultivation and selection. I am not aware that its improvement has ever been undertaken systematically; the field is certainly not without promise. Some of the large flowered forms are often found in American nurseries, grafted as standards on tall stems of the Mountain Ash; it is, however, a far handsomer plant if allowed to grow naturally on its own roots, when it forms a tall, upright, and rather compact shrub, which is beautiful from spring to autumn.

Of the two species of *Hudsonia* which are found in the Northern States, the earliest, *H. ericoides*, is now in bloom. It is a bushy, heath-like, dwarf shrub, rarely exceeding six or eight inches in height, covered with slender, awl-shaped, greenish leaves, and producing numerous small, fugacious, showy yellow flowers along the upper part of the branches. This is a very common plant along the sea coast of the New England and Middle States, where it often covers broad stretches of dry, sandy, barren soil, making a conspicuous and beautiful appearance when in flower, and later in the season masses of agreeable gray-green foliage. The *Hudsonias* are not easy plants to establish in cultivation, but once established they grow and spread, especially if they can be slightly protected in winter. They are excellent dwarf rock-garden shrubs, or they can be used as a carpet about taller growing plants.

Neviusia Alabamensis is one of the rarest of North American shrubs, being known only in one locality—the cliffs of the Black Warrior River, in the town of Tuscaloosa, Alabama. The rarity of this plant, the peculiar structure of its flowers, and its relationship, which Professor Gray pointed out long ago, to the eastern Asian genera, *Kerria* and *Rhodotypos*, are sufficient to make its cultivation interesting. The clusters of flowers, moreover, with their long white stamens, are very beautiful, and make this plant a most desirable addition to any garden. The *Nevusia* is a shrub four or five feet high, with erect or spreading branches, short-petioled, membranaceous, ovate, doubly-serrate leaves and solitary or fascicled flowers, which are borne on long, slender peduncles from the extremities of short lateral branches. They have foliaceous calyx-lobes, no petals, and several rows of long stamens, which make the flowers conspicuous and showy. The *Nevusia* is perfectly hardy here, and may be propagated by cuttings as readily as any of the *Spiræas*. It is figured in the sixth volume of the new series of the *Proceedings of the American Academy of Arts and Sciences*, in which will be found a detailed account of this plant and its botanical affinities, from the pen of Professor Gray.

Pyrus fennica, a native of the mountainous parts of central Europe, and by some botanists considered a natural hybrid between *P. intermedia* and *P. Aucuparia*, although reproducing its

characters from seed, is in bloom. It has been described under many names, of which the most common of those still in use are *Sorbus hybrida*, *Azardus pinnatifida*, *Sorbus fennica*, *Pyrus pinnatifida* and *P. sorbifolia*. It is sometimes known in nurseries as *Sorbus quercifolia*. It is a small tree, with smooth yellow-brown bark and erect branches, which attains, under favorable conditions, a height of forty or fifty feet. The leaves are four to six inches long, deeply pinnately cut or almost pinnate at the base, the under side as well as the peduncles and young shoots densely hoary-tomentose. The flowers are creamy white, half an inch across, and borne in wide branching corymbs. The pome is small, rarely more than half an inch in diameter, and dull scarlet in color. *Pyrus fennica* is a plant of very considerable ornamental value; it is very hardy, and grows rapidly, and thus far has not been attacked here by insects; although, like the Mountain Ash, it will doubtless suffer from borers. Specimens differ considerably in the size, and especially in the cutting of the leaves.

Among the White Service trees (*Pyrus Aria*) in the Arboretum by far the handsomest is one received several years ago from the *Arboretum Segrezianum*, under the name of *Pyrus Decaisneana*, a variety probably of the common *P. Aria*, which, however, does not seem to have been described, and which does not differ from the species except in its broader, brighter green leaves. It has broadly ovate, doubly serrate leaves, dark green and shining above, covered on the lower side, as well as the petioles and peduncles, with a dense white tomentum. The White Beam tree and its numerous varieties are rarely seen in American gardens. Many of them are very hardy, however, and possess, as ornamental trees, valuable properties. They are natives of northern and central Europe, the Himalaya and some parts of central Asia. The White Beam is a low, round-headed tree, sometimes twenty to thirty feet in height, and sometimes, especially in northern Europe, a low bush. It forms a compact mass of bright green foliage, with which the white covering of the under sides of the leaves, when the wind stirs them, makes a pleasant contrast. It is handsome when covered with its scarlet fruit; and in winter, too, when its smooth branches and large green buds are exposed. The rather small creamy white flowers produced in branching corymbs are not very showy. The White Beam may be raised from seed; the fine varieties, however, can only be perpetuated by grafting, the Mountain Ash being often used as the stock. Like the Mountain Ash, this tree is liable to be attacked by borers.

Symplocos paniculatus is a hardy ornamental Japanese shrub now in flower. It has attained a height of four or five feet. The branches are stout, erect and covered with light brown slightly scaly bark. The young shoots are hairy pubescent. The leaves are dark green, ovate acute or sometimes slightly obovate, one or two inches long, minutely serrate, conspicuously reticulate-veined, scabrous on the upper side, softly pubescent below, especially along the mid-rib and primary veins. The small white flowers, less than half an inch across when expanded, are produced in short, loose panicles, one or two inches long, terminal upon short lateral leafy branches, which appear in great profusion along the principal stems. The fruit is blue, the size of a pea. The introduction of this very beautiful and interesting addition to our list of hardy shrubs is due to the Messrs. Parsons, of Flushing, who sent it to the Arboretum several years ago.

Among climbing plants none are hardier and few are more vigorous here than *Schizandra (Maximowiczia) Chinensis*, a member of the Magnolia Family, and a native of Manchuria, northern China and Japan, where it is often seen in the forests climbing over trees to a height of twenty or thirty feet. The long flexuous branches are covered with red warty bark. The leaves are two or three inches long, obovate or obovate-elliptical, sharply acuminate, serrate, and slightly pubescent on the under side along the principal veins. The flowers are produced in few flowered axillary fascicles which are completely hidden by the leaves. They are long peduncled, drooping, three-quarters of an inch in diameter, pale rose-colored and deliciously fragrant, and are followed by scarlet baccate fruits, an inch in diameter, and which remain a long time upon the plant. This is a very hardy and fast growing vine, which might be cultivated much more frequently than it is in this country.

Cytisus biflorus, a native of Hungary, is a very hardy shrub here, two to three feet high, with rigid, stout branches, and one of the showiest species of the whole genus, which can be grown in this climate without protection. It has oblong bright yellow parallelly paired flowers an inch and a quarter long, and longer than the small ternate silky leaves. *Cytisus purpureus*, a native of the central European mountain ranges,

is a very hardy and desirable dwarf shrub in this climate. It has procumbent, twiggy stems, solitary axillary, handsome purple flowers, and small, smooth leaves with oblong leaflets. It is sometimes grafted as a standard upon tall stems of the Laburnum, but in this climate it is more successful when grown upon its own roots.

The common Broom of Europe (*Cytisus scoparius*), a tall shrub, five to ten feet high, with small trifoliate leaves and handsome, solitary, axillary yellow flowers, produced in the greatest profusion during several weeks, is unfortunately not quite hardy, but with a slight covering in winter blooms profusely. This is one of the best known and most beautiful of European shrubs. *Cytisus albus*, the beautiful white Spanish Broom, requires also some protection here in winter. It has tall flexuous branches, just now covered with racemed fascicles of pure white flowers, and small silky trifoliate leaves. Like the last, it is well worth the trouble of the slight winter protection necessary to insure its profuse flowers.

The double-flowered form of *Wistaria Chinensis*, in which the stamens are all developed into petals, is rarely seen in flower here. It is one of the plants sent to this country from Japan by Mr. F. Gordon Dexter twenty-five years ago, and afterwards propagated and distributed by Mr. Francis Parkman. It is now in flower probably for the second or third time only in the neighborhood of Boston. The flowers have little beauty in themselves, and as the plant is such a very shy bloomer, its cultivation cannot be recommended.

June 8th.

7.

The Forest.

Dispersion of Seeds and Plants.

SOME time ago Mr. D. Morris, in a contribution to *Nature*, cited numerous instances in which birds had taken an active part in the distribution of seeds and plants. Birds, it is true, from their greater adaptability to rapid and extensive locomotion, are more concerned in this work than other animals, but they are, by no means, alone in scattering seeds. In *Nature* for March 15th Mr. Morris contributes further notes upon this subject, from which we quote:

"It may seem strange, at first sight, to assert that cattle have been the means of distributing the seeds of certain plants from one country to another, but a statement is made by Griesbach* respecting *Pithecolobium Saman* (N.O. Leguminosæ), a large tree native of Tropical America, now naturalized in Jamaica, that the 'seeds were formerly brought over from the continent [of America] by cattle.' This statement has been carefully examined and it is fully borne out by facts. Formerly, Jamaica, like Trinidad at present, was dependent for cattle on Venezuela. The food of the animals during their voyage consisted, amongst other things, of the pulpy legumes of *Pithecolobium Saman*. The seeds being very hard were uninjured by the process of mastication and digestion, and they were dejected by the animals in the pastures, where they germinated and grew up into large trees. In this instance the seeds were carried across the sea a distance of about a thousand miles, and there is no doubt that the cattle were directly concerned in their introduction. Indeed, without them the seeds, even if accidentally introduced amongst the fodder, would not have been placed under such circumstances as would have enabled them to give rise to plants. In the first place, by being passed through the animals the seeds were softened and the period of germination hastened. In the second place, being embedded in the droppings of the animals the seeds had a suitable medium to protect and promote germination; and this medium enabled the young plants to withstand the season of drought which is incidental to almost every tropical country. In this instance we have cattle not only the means of introducing the seeds of a valuable tree, but also involuntarily instrumental in establishing the tree in a new country, and providing shelter, shade and food for their progeny. Those acquainted with the guango or rain tree, as this *Pithecolobium* is locally called, will fully realize its value as a shade and food tree for cattle, and they will also appreciate the singular concurrence of circumstances by means of which such a tree was introduced to a new country by the very animals which required it most.

"It is possible there may be some one who will doubt the possibility of seeds retaining the power of germination after undergoing the processes of mastication and digestion, and especially in the special case of ruminating animals. There

* "Flora, British West India Islands," p. 225.

is, however, very clear evidence on the subject. It is a common occurrence in India to utilize the services of goats to hasten the germination of the seeds of the common *Acacia arabica*, known as the Babul. This tree belongs to the same natural order as the *Pithecolobium*, and grows in the poorest and driest soils of India. The Babul seeds will not germinate readily in the hot weather, and it is the regular habit, in order to save a season, for a person desirous of a crop of seedlings to make a bargain with a herdsman or a neighbor who possesses a flock of goats to quarter them for some days in a small inclosure in which they are fed on Babul leaves and pods. The droppings of the animals contain a certain number of seeds which are uninjured, and these now readily germinate, and give rise to plants the same season. I am informed by Dr. Watt that in India 'several other plants are treated in the same way.' The seeds of the several species of cultivated Guava are hard and do not easily germinate. These, however, are said to germinate more freely and readily when they are picked up in night soil.

"While on this subject I would mention that when at St. Helena in 1883 I expressed some surprise that no attempt was made to utilize 'urban' manure in the neighborhood of Jamestown, when the land was so impoverished and yielded such poor crops. I was met by the fact that if such manure was largely used the land would become over-run with plants of the Prickly Pear, *Opuntia Ficus-indica*, the fruit of which is largely consumed by the inhabitants. There is little doubt that the seeds of this plant, like those of the Guava, and I suspect also species of *Passiflora*, which are swallowed whole, are capable of germination after they have passed through the human body. Another instance occurs to me where the use of manure has been the means of distributing an undesirable plant on cultivated lands. In many tropical countries a grass known as Para, Mauritius, or Scotch Grass, and sometimes as Water Grass (*Panicum barbinode*), has been introduced from Brazil, and highly esteemed for its rapid growth and nourishing properties. It grows well in moist situations on the banks of streams, and even in soils so swampy as to be suitable for nothing else. In such situations it spreads rapidly and yields abundant food for cattle and horses. Nothing, however, could be worse than this grass for cultivated areas, where the land is required to be kept free from weeds, and where crops of Sugar-cane, Coffee, Tea and Cacao are raised. It has been found that where animals are fed on this grass the joints, even after passing through the animals, have been known to grow. Hence the manure, if freshly used, has been the means of establishing the plant over wide areas."

Mr. Morris then cites the Cardoon and common Stork's-bill (*Erodium cicutarium*) as plants which have spread over wide areas in South America through the instrumentality of cattle. In the latter instance the seeds become attached to the legs and bodies of the animals by means of their bearded carpels, and in this way they are carried over wide areas.

He then continues:

"In the Island of Jamaica we have a remarkable instance of the naturalization and wide distribution of an introduced plant in the case of the Indian Mango. In an official report, published in 1885, I stated that to the Mango, possibly more than any tree in the island, is due the reforesting of the denuded areas in the lower hills; and as in consequence of the changes taking place in the climate members of the indigenous flora are unable to maintain their ground, it is fortunate the island possesses, in a vigorous and hardy exotic like the Mango, the means of counteracting the baneful effects of deforestation. It specially affects land thrown out of cultivation, and the sides of roads and streams where its seeds are cast aside by man and animals. It practically reclothes the hills and lower slopes with forest, and it enables the land to recuperate its powers under its abundant shade-giving foliage.* It is strange that in Ceylon, which is so much nearer the home of the species, the Mango does not spread by self-sown seedlings. We cannot say why such anomalies exist. They do exist, however, and offer problems which can only be solved by a closer study of the conditions of plant life, and the interdependence of plants and animals acting and reacting one upon the other.

"The Orange tree was introduced to Jamaica more than a hundred years ago. It is now found practically wild over the settled parts of the island, and the fruit is exported to the value of nearly £50,000 per annum. Up to quite recently very few

trees were planted. Nearly the whole were sown by the agency of frugivorous birds, who carried the seeds from place to place and dropped them in native gardens, Coffee plantations, Sugar estates and Grass lands. In such localities the Orange trees grew and flourished, and now a demand has arisen for the fruit in the United States an important industry has been established, the active agents in which have been birds. The agency of birds in the distribution of the seeds of plants is too large a subject to be discussed at length here. A valuable contribution of facts in this direction has lately been made by Dr. Guppy in his important work on the Solomon Islands. As the most recent addition to our knowledge of what takes place in oceanic islands at the present time, it deserves careful attention. It will suffice only to quote one or two sentences: 'Whilst through the agency of the winds and currents the waves have stocked the islet with its marginal vegetation, the fruit pigeons have been unconsciously stocking its interior with huge trees, that have sprung from the fruits and seeds they have transported in their crops from the neighboring coasts and islets. The soft and often fleshy fruits on which the fruit pigeons subsist belong to numerous species of trees. Some of them are as large even as a hen's egg, as in the case of those of the species of *Canarium* ("Ka-i"), which have a pulpy exterior that is alone digested and retained by the pigeon. Amongst other fruits and trees on which these pigeons subsist, and which they must transport from one locality to another, are those of a species of *Elaeocarpus* ("toa"), a species of Laurel (*Litsea*), a Nutmeg (*Myristica*), an *Achras*, one or more species of *Areca* (Palm), and probably a species (of another Palm) *Kentia*.'

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—Referring to the notes on *Ficus aurea*, published in your issue of May 9th, it may be interesting to record the fact that to my personal knowledge this tree is quite common on most of the islands, and that it is occasionally found on the mainland of the west coast of Florida, as far north as Tampa Bay. A specimen, almost equal in size to the famous Key West tree, stands on Sneade's Island, at the mouth of the Manatee River, and there is another on the opposite point (Shaw's Point) almost as large, while specimens with an entire stem-diameter of from two to four feet are not uncommon. It is quite plentifully found on Terra Ceia Island in Tampa Bay, on Anna Maria, Long, Sara Sota, and Casey's Keys, and I remember having seen it often on the Charlotte Harbor keys, the Chockaliska Islands, etc.

Some of the Florida nurserymen have been propagating and selling the plants for the past four years. A quicker and easier method of propagation than from seed, is from cuttings. During the rainy season of our Florida summer, every cutting strikes readily without artificial heat, in one or two weeks. An advantage of *Ficus aurea* when used as a decorative plant, is that it is not such a slow grower as *Ficus elastica*.

The fact that this tree has not been reported before from the west coast is an indication of the botanical exploration still needed in Florida. The impression seems to prevail that the west coast of Florida is uninteresting, and certainly its plants are very imperfectly known. In Chapman's "*Flora of the Southern States*," for instance, three of our most conspicuous species of native Cactus are not mentioned: *Cereus variabilis*, found all along the west coast from Punta Rassa southward, in dense masses and almost impenetrable jungles, the terror of the settler who tries to plant a tomato patch on new ground; it is also found on the east coast, I cannot say how far north. Another *Cereus*, thought by some to be *C. colubrinus*, but which seems to me to be entirely different, and which is found quite frequently along the coast from Tampa Bay, as far, at least, as to Key Largo; and *Opuntia Tuna*, with which our whole coast and ranges of keys fairly bristle; Indian Key especially presents a *chevaux de frise* of this plant which is appalling.

Among our native species of epiphytal Orchids, *Epidendrum rigidum* and *E. bidentatum* have only been recently known to botanists. *Cyrtopodium punctatum* has been found at Caximbas and at Chockaliska on the west coast, as well as at Miami.

Manatee, Fla., May 21st, 1888.

P. W. Reasoner.

[These new stations for Florida plants are interesting, especially as indicating how much field-work must still be done before the plants of the Florida peninsula and their distribution are thoroughly known. Botanizing in southern Florida has always been and

* Annual Report, Public Gardens and Plantations, Jamaica, for the Year 1884, p. 45.

is still attended with great expense and many serious discomforts. Every year, however, adds new species to the Florida flora, and new facts relating to the range of Florida plants, especially of those of West Indian origin. Our correspondent can render a real service to American botany by carefully exploring the west coast from Cedar Keys to Caximbas Bay, which, as he suggests, is, so far as the plants are concerned, the least known part of Florida. This is now one of the best botanical fields in the country in the prospect it offers for new species, or species new to the United States.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—Many years ago a nurseryman in Nebraska had his stock devoured by grasshoppers and failed to pay us. Two years ago last autumn he wrote us that he had a very large stock of Green Ash seedlings that were very fine, and that he would load a car with 250,000 of them in exchange for his note that we had held for over ten years.

The trees were dug early in November, 1885; they were longer than usual in transit. Our books show that we paid the freight November 28th, but as our freight bills are not paid until the latter part of each month, this does not establish the exact date when the plants were received.

Mr. Geo. Ellwanger called on us in June, 1886, and was surprised to see nearly 100,000 of these trees piled up in bundles of 200 trees each, covering a space about eight feet long, six feet wide and about three feet deep in one corner of our frost-proof packing shed. We sent Mr. Ellwanger a bundle from the same lot of trees in the spring of 1887, after they had lain another year undisturbed. This was a greater surprise than ever, and to surprise him even more than last year, we send him another bundle to-day by mail from the same pile, thirty-one months from the time the plants were dug. No earth or other material has touched them during these thirty-one months, except the earth floor and a quantity of forest tree leaves laid over them when they were placed in the packing house in November, 1885.

We send you also a package from the same lot. The wide doors have been left open this cold, backward spring, and I see the buds have started. I have had the doors closed and directed our packer to send you a package from the same pile next May.

Waukegan, Ill.

Robert Douglas.

[The plants have been received from Mr. Douglas. They are in excellent condition; the wood is perfectly fresh and healthy, and the buds are all alive. We do not recall a case of arrested vitality prolonged during so many months.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—When we consider the large number of horticultural magazines, seedsmen's catalogues and other sources of horticultural knowledge, it is difficult to account for the popular misinformation concerning the names of plants, the manner of their propagation and reproduction, their habits and their uses. This ignorance is not by any means confined to the illiterate. Cultivated people in city and country seem ready to believe any absurdity relating to plants, and to accept any name that is given them, as genuine. More surprising still, we find the daily newspapers circulating the most absurd statements, as, for example, we are told in a certain Boston daily that "a horticultural novelty is a Peony which has caught the hue, shape and perfume from a Rose which overshadows it." A leading New York newspaper gravely gives its readers the following information relative to floral fashions: "Pink and yellow are the favorite colors this season, the Bowarria or Paris pink being especially popular." The following item has been going the rounds of about all the papers in the country: "Seedless raisins are obtained by burying the end of the vine in the ground when the Grape is half ripe. This prevents the formation of seed and the full development of the fruit, but it ripens all the same, and has a delicious flavor."

Such nonsense would be laughable if it were not disgraceful. In no other department of a daily newspaper would such ridiculous blundering be tolerated. Each paper has its musical critic who can pick oratorios and operettas to pieces without a slip of the pen. Articles are written on fashions in dress, where the reporter trips through Youghal lace, guipure and appliqué without ever a misstep. The papers would not dare to publish under these heads any such stuff as they do regard horticultural and floral matters.

It would seem that the horticultural and floral interests in this country are large enough now to insist upon greater accuracy when matters of interest to them are reported. There is no good reason why information of this kind should not be as carefully prepared as that relating to dress, music, the drama, or any other department of society news.

If the horticultural press would treat these misstatements and blunders with the prompt ridicule which they deserve, I believe that a much needed reform would soon be effected.

Boston.

William J. Stewart.

To the Editor of GARDEN AND FOREST:

Sir.—If your correspondent who recently wrote of the Norway Spruces in the Central Park would visit Greenwood Cemetery I think he would find new occasion for complaint. All through the cemetery half-dead Spruces injure that effect of successful care and vigorous life which, without them, would be so satisfactory. And if they seem obtrusive in the park, even apart from their unhealthy condition, such is still more the case in the cemetery, where they have been planted in the most inappropriate and inartistic way among groups of fine old native trees. Yet they look worse, perhaps, along the approach to the main entrance. Here a long row to the right of the road lift their thin, spindling, black and decaying forms close in front of some flourishing Silver Maples. As the Maples are there, the Spruces are unnecessary. They are already injuring the growth of the Maples, and the dreariness which they give to the scene is anything but desirable in a cemetery approach.

Brooklyn, June 1st.

Lot-Owner.

Periodical Literature.

The *Book Buyer* for June opens with an article by Miss Edith Thomas called "Pleasant Ways Through Wood and Field," which is worthy of its attractive title. It is a good example of those little "prose poems" with Nature for their subject, to the growing multiplicity of which we have already referred as among the happiest signs that the American people is redeeming itself from the old reproach of being a people without true sentiment, keen appreciation of beauty, or delight in the "unimproved" works of God.

Lippincott's Magazine for May contains a pleasant anonymous article entitled "Among My Weeds," in which the author tells how she turned a "barren bit of earth" on the top of Meridian Hill, near Washington, into a delightful spot, simply by helping Nature to do the work in her own way. The existing "crop of stones" was removed from the surface and piled into heaps and a crop of ruddy Sorrel immediately appeared. Then Raspberry bushes were encouraged to grow along the fences and around the heaps of stones. Wild flowers sprang up and a very little attention brought them to beautiful development. Mullein-stalks grew twelve feet tall and showed unsuspected charms of line and color, and "decent treatment" made of a Pokeberry a bush ten feet in height, "laden with berries that would make at least a barrel of blood-red ink." The writer tells with pardonable pride of the way in which passers-by stopped to admire her "weed garden," and her charming account of it should give comfort and inspiration to those who think they must hire a gardener and exhaust a florist's catalogue if the surroundings of even the simplest country home are to be redeemed from barren nudity. As she truly says, the weeds of one country are often florists' favorites in another; and the lesson of her article will be reinforced if the American reader will glance through the pages of those English trade catalogues where so many of our despised roadside and pondside weeds are recommended as both easy to grow and very beautiful when grown with a little care.

Notes from the Paris Horticultural Exhibition.

ONE of the striking features of the excellent exhibition this year was the tuberous Begonias. M. Robert, of Vésinet, had a wonderful collection of these plants, which have received so much attention in France. The flowers, both single and double, were very large, and the colors were superb, ranging through every shade of red, pink, orange and yellow, as well as the purest white. A group of eleven hybrids of *Begonia Rex* and *B. Diadema* demonstrated in a remarkable way the possibilities with these plants. The collection of Roses was large, embracing about three thousand plants. Among the Tea Roses, Charles Lévêque, Sunset and Marquise de Viviers attracted the most attention, while Captain Christy, among the hybrids, led off, with Madame de

Watteville, Comte de Paris, Gloire de Margottin, American Beauty, Victor Hugo, Duke of Edinburgh, and others following hard after. In the Polyantha Roses, Ma Paquerette and Mignonette were very best. A curious orange-yellow single Rose, Ma Capucine, was among the conspicuous favorites.

The best collection of Orchids was shown by Messrs. Sander & Co., of St. Albans, England, and it won the *Grand Prix d'Honneur*, offered by the President of the Republic, for the finest exhibit.

An excellent collection of Clematis was sent by M. Cristen, of Versailles, of which the following were the best: Paul Avenal, Eugène Delattre and Lady Caroline Nevill, of the purple sorts, and Marie Boisselot and Miss Bateman among the white ones.

The Rhododendrons were in great variety and well grown, while the Azaleas, both *A. mollis* and Ghent varieties, were superb. A collection of Kalmias was only fair. Not as much is made of this plant in France as should be. Especially good were a group of double Petunias, one of Ericas, one of Maidenhair Ferns (*Adiantum*), to which should be added an interesting collection of "Carnivorous Plants" from Messrs. Veitch, of London.

The cut flowers and fruits, with very few exceptions, were not remarkable; but the show of vegetables was excellent, especially the different salad plants and the Asparagus. An odd feature was a quantity of Mushrooms actually growing.

Paris, May 28th, 1888.

H. S. C.

Notes.

According to the *Woman's Journal*, Mrs. Julia Ward Howe was recently presented in Ventura, California, with a Lily stem which bore 134 blossoms.

Dr. M. T. Masters, editor of the *Gardeners' Chronicle*, has been elected a corresponding member of the Institute of France (section of botany) in place of the late Asa Gray.

At the recent meeting of the Association of American Nurserymen, at Detroit, Mr. George A. Sweet, of Dansville, N. Y., was elected President, and Mr. Charles A. Green, of Rochester, Secretary of the Association for the current year.

The *Bulletin* of the *Société d'Acclimatation* in Paris mentions the fact that a large consignment of Oranges from Australia recently arrived in London in good condition. As the seasons are reversed in the Southern Hemisphere, Oranges there produced may supply the European market when the crops of Spain and Algeria have been exhausted, and it is asserted that if packed in sawdust, or enveloped in paper impregnated with an antiseptic preparation, they may be almost indefinitely preserved.

The wife of Monsieur de Nadaillac, a famous French Orchid collector, was a very skillful painter of flowers, and four large volumes, containing water-color pictures from her brush, representing more than 300 species or varieties of Orchids, has recently been presented by Monsieur Delessert to the library of the Museum of Natural History in Paris.

The *Revue Horticole* recently noted the extent to which fruits and vegetables are now being exported from America, and gave as one reason why they can be sold at sufficiently low prices the fact that their cultivation is greatly specialized. In illustration a Celery farm at Kalamazoo, Mich., is cited which covers 2,000 acres of ground, produces each day, during the season of six months, nearly fifty tons of Celery, employs 1,800 workmen, and directly or indirectly supports some 3,500 persons.

The following uncredited item is going the rounds of the horticultural press:

At a recent horticultural meeting flowers were exhibited in a glass filled with water and fitted with a wide and flat stopper. To the stopper the flowers were attached and then carefully introduced into the water in the globe, the stopper completely filling the mouth of the globe and being wide enough to stand safely. By turning the whole arrangement so that it stood on the stopper, the flowers were left completely surrounded by water. The water magnified the flowers and a pleasing optical illusion is the result. Flowers thus immersed will keep twice as long as those in the air.

A German resident of Barcelona recently published the fact that severe attacks of influenza—exactly like those which we call in this country "rose" or "hay colds"—have afflicted the

members of his family year by year in spring, and that he has at last traced them with certainty to pollen dust from the Plane trees which surround his home. A German scientific journal thereupon declares that the evil influence of Plane tree pollen upon the stomach, throat, eyes and ears was a well known fact in antiquity, both Dioskorides and Galen having called attention to it. That German scientific men will acknowledge that an influenza may be produced by pollen dust of any kind will surprise many American travelers; for many must remember their experience with German physicians, who have laughed the idea to scorn, refusing to believe in the periodicity of the attacks from which their foreign patients suffer, or in the potency of the cause to which those patients attribute them.

Retail Flower Markets.

NEW YORK, June 22d.

Business has quieted down among our florists, but it is not yet at the usual summer ebb. The demand from suburban districts is just beginning, for some resorts have opened, and many cottagers are giving lawn parties. Hybrid Roses are all out-door grown, and show general imperfections in flower and foliage. American Beauties are by far the best. A few Baroness Rothschilds come in good shape, but are small. The range in price of hybrids is a long one, as they cost from 15 cts. to 50 cts. each. Selected ones hold at \$6.00 a dozen. Marechal Neils, Brides and Mermets bring \$1.50 a dozen. The latter are small and pale. Perles, Niphotos and Souvenir d'un Ami are \$1.00 a dozen. Gen. Jacqueminot Roses are decidedly poor and are \$1.00 a dozen. Fine La France Roses bring \$3.00 a dozen. Pæonies cost 15 cts. each. White ones are in good demand. Gladioluses are \$1.50 a dozen spikes. Callas are scarce and cost \$3.00 a dozen, the same as *Lilium longiflorum*. Fancy Carnations with long stems cost 50 cts. a dozen. Garfields and Heintz's White sell for 35 cts. a dozen. Mignonette costs 50 cts. a dozen, and Lily-of-the-Valley 75 cts. Field Daisies are 25 cts. and Pansies 35 cts. a dozen. Sweet Pea blossoms cost 35 cts. a dozen. These with Moss Roses, which are down to \$2.00 a dozen, are the choicest flowers in stock. Sweet Alyssum, finely grown, is sold for 35 cts. a dozen sprigs. Smilax, which looks thin and sickly, is 30 cts. a string. There is some demand for Rose Geranium foliage, which is sold for 25 cts. a bunch.

PHILADELPHIA, June 22d.

Trade is now very dull. What flowers are sold are disposed of in the morning. First-class flowers are very scarce. The hot, dry weather is very severe on them, both under glass and out-of-doors. Stephanotis is quite plentiful, but is used only in designs, or as boutonnières, for which latter purpose they sell at from 15 cts. to 25 cts. per spray. Out-door Roses are nearly over. American Beauty, grown under glass, sells at \$3 per dozen; La France, Mermets and Brides, \$1.50; Perles, Sunsets, Niphotos, Mad. Cuisin and Bennetts, \$1. Water Lilies are 10 cts. per bunch of three flowers. Sweet Peas, Corn-flowers, Nigella (Love-in-a-Mist), and Forget-me-not, 25 cts. per dozen. Pæonies cost from 10 cts. to 25 cts. each. Carnations, Crimson King, Buttercup, Grace Wilder and the scarlet varieties, are 25 cts. per dozen. Gardenias are 25 cts. per flower. Field Daisies, 25 cts. per dozen. Single Dahlias, \$1 per dozen. *Lilium Candidum*, \$1.50 per dozen. Gladiolus, 15 to 20 cts. per spike. Smilax, 50 cts. per string. Asparagus, 75 cts. Adiantum fronds, 35 cts. per doz. Candytuff and the double white Feverfew (*Pyrethrum*) is largely used in *set* pieces; so also is Spiræa and the white Snowball; these are rarely sold alone.

BOSTON, June 22d.

Out-door Jacqueminots are coming in freely, and are unusually full and good, with bright, clean foliage. They cost \$1.00 and \$1.50 per dozen. Hybrids are not in yet, but a few warm days will bring them on in full blast. White Roses are very scarce and have been in great demand for weddings. Cooks and Brides are worth \$2.00 to \$3.00 per dozen, and good ones are hard to find. Good Niphotos are also scarce, at \$1.00 per dozen. The annual school and seminary graduations always make June a busy month for the florists, as the custom of sending baskets and bouquets of flowers to the graduates has become very general. Mermets, Bon Silenes, La France and other pink Roses are very abundant and are worth 75 cts. to \$1.00 per doz. Yellow Roses, such as Perle and Marechal Neil, are not so plentiful, costing from \$1.00 to \$1.50 per dozen. Carnations are greatly overstocked and can be bought in any and all colors for 25 cts. per dozen. Pæonies, Irises, Syringas and other out-door hardy flowers help to make the florists' windows attractive. Among the prettiest blossoms now seen are the bright yellow Coreopsis blooms. These bring 50 cts. per dozen. The first lot of pink Pond Lilies has just come, and these can be had continuously for the next two months; \$3.00 per dozen is the ruling price. Lily-of-the-Valley of the best quality is \$1.50 per dozen. Some of the florists are making a specialty of the Sprays of Allemanda with its bright yellow flowers, and Bougainvillea with bright pink clusters. These vines make beautiful table decorations. They are worth \$5.00 per dozen sprays. Cattleyas cost \$1.00 per flower. These are about all the really choice varieties offered. Mignonette, Marguerites, Stocks, Pansies, etc., are of poor quality and cheap.

Prospect Park.

PROSPECT PARK, in the City of Brooklyn, is one of the great artistic creations of modern times. It is the best expression of the creative powers of masters in the art of landscape-making, who, more fortunate here than elsewhere in features of natural beauty, and especially in a native growth of majestic trees, were able to produce an urban park unsurpassed in any part of the world in the breadth and repose of its rural beauty.

The condition of this great work of art, which, under the most favorable circumstances, could not attain its full beauty and usefulness for another century at least, is, in some respects, deplorable; and if we can judge by the contents of the twenty-seventh report of the Brooklyn Park Department, the ideas held by the Board of Park Commissioners with regard to the responsibilities of their office, are not calculated to inspire confidence in its future.

The plantations in many parts of the park, were made with a view to results that could only be obtained by a gradual and discriminating thinning-out of many trees and shrubs originally planted thickly. This has for years been shamefully neglected. The Commissioners have at last been impressed, however, by the immediate results of this neglect, and have determined to make up for the neglect of their predecessors. Their report gives no sign, however, that they have proceeded with any understanding of the original motives of the plantations, that they have desired to understand them, or have given them any consideration. All they say of their doings, at least, indicates the contrary.

Let us consider what they are likely to accomplish. An urban park is useful in proportion as it is rural. The real, the only reason why a great park should be made, is to bring the country into the town, and make it possible for the inhabitants of crowded cities to enjoy the calm and restfulness which only a rural landscape and rural surroundings can give. This is why a large park is better than many smaller ones, and why all other objects must,

in a great park, be subordinated to the one central, controlling idea of rural repose, which space alone can give. A park is useful as a playground, or as a breathing space in a city, or as a picnic ground; it may be made interesting by the plants which it contains, or by the equipages which throng its drives; but its real object, its highest claim, to take rank among the best productions of modern civilization, is found in the rest of spirit it can bring to the souls of the weary dwellers in cities. It was with this feeling and with this understanding of what a park should be, that Prospect Park was designed and executed, and anything which is done to lessen its usefulness in this direction is a calamity which persons who only look upon a park as a good place in which to play ball, or drive a fast horse, do not readily appreciate.

To the expression of rural repose in a park, three things are supremely necessary; first, a considerable extent of actual space of natural landscape; second, indefiniteness or mystery of the outlines of the actual landscape space, obtained by curtaining off with natural bodies of foliage such outside objects as the eye would otherwise rest upon; third, by subordinating necessary artificial objects within the park so far as practicable to its natural elements.

The easiest way to destroy the rural character of a park and limit its apparent extent is to open its borders so that outside objects can be seen from within. There is danger that the Prospect Park Commissioners, in their unadvised cutting, will do this. The thinning-out of plantations like those in Prospect Park, where so much depends upon unity of expression and harmony in composition, is a matter of such delicacy that it cannot safely be entrusted to any one but an expert trained in the consideration of the necessities of similar cases. If the Commissioners appreciate the responsibilities which they have assumed in taking charge of such a creation as this park, they will inaugurate a systematic thinning of the plantations under some competent authority, and not trust their own inspirations.

Particular attention was given in the design for Prospect Park, to providing proper accommodation for the enjoyment of out-door concerts. The principal artificial feature of the Park, is the noble lake; in this lake and close to the most picturesque part of the shore a little island was made to serve as a music-stand, while on the adjacent shore a wide and beautifully planted promenade, unsurpassed in extent and completeness of arrangement, was to offer to pedestrians every opportunity to listen to the music, which the occupants of carriages might hear equally well from two large gravel concourses, specially designed for this purpose. The most costly work upon the park was used in the decoration of these arrangements. Extensive refreshment-houses, fountains, seats, broad flights of stairs, superb terrace-walls of sculptured stone with bronze ornaments—all were designed as parts of one scheme embodying the purpose of assembling great bodies of people, within hearing distance of a central point. The outlines of the lake for a long distance were determined with reference to this purpose, bridges were planned, and boat-landings and approaches from all directions laid out with reference to it. The expenditure for the purpose must have amounted to several hundred thousand dollars. The designed use of the arrangement was delayed until the trees planted for shade should have grown to serve their purpose. Now that they have done so, the Commissioners state that they have satisfied themselves, by an experiment, that the acoustic effect of the music from the point intended would be a failure. There are few questions more difficult and with regard to which ordinary architects and ordinary musicians are more in doubt, than that of the minor conditions by which the effect of music is heightened or marred. What recognized master in the science of acoustics the Commissioners employed, what variety of experiments were made, to what extent they were carried, and upon the verdict of what jury of experts their decision was reached, is not to be learned from their report. The

conclusion announced is simply that the scheme, the required outlay for which had been almost entirely made before that time, has been abandoned; and that the Commissioners have built a permanent music-stand under the shadow of a trimmed-up old natural wood, in a part of the park to which the original design provided no suitable approaches, having in view the maintenance of the secluded sylvan character which it originally possessed. The construction which the Commissioners have here erected combines, they state, the purpose of a storage house, of a music-stand, and of a battle-monument, the latter being realized by giving its basement the semblance of a fortification.

The noble plaza outside the principal entrance of the park is described by the Commissioners in their report as a "great failure, suggestive of Siberia in winter and Sahara in summer," and it is suggested to convert it into a garden after the fashion of the Public Garden in Boston. It is evident that the Commissioners do not understand the motives which led to the creation of the plaza, which is really one of the great features of the park, and which provides, among other things, a proper place in which great public meetings can be held outside the park itself. To those who have seen the effects of public meetings upon the London parks, the establishment of this broad paved plaza will seem a wise provision indeed. It greatly facilitates, too, the entrance of carriages into the park as the currents of street traffic approach here upon lines coming from six different directions, which without the plaza would create hopeless confusion.

But it is not necessary to cite other examples of the mental condition of these Park Commissioners as displayed in this remarkable report.

Enough has already been said to show how great the danger is which constantly threatens not only Prospect Park, but all our public parks, and how great is the necessity that the people who inhabit our cities should fully appreciate and understand the real objects for which parks are created. Until the public is educated in all that relates to parks, and until its interest in them can be stimulated and maintained, it seems impossible for an artist to make a design for a public ground, with any hope that his plan will be realized. Let the motives of such a design be studied and adapted with the greatest care; let them be elaborately discussed and illustrated and explained; even if the public approves and endorses them for years and millions are expended in putting them into execution, the time will come, as it has now come in Brooklyn, when a body of men, with no higher claims upon the confidence of the public than their predecessors, will enter upon their duties, either in utter ignorance of what those duties really mean, or with the purpose of ignoring the original motives which governed the construction of their trust, and of seeking for excuses to build a new park upon its ruins. This is a matter of more than local significance and importance. Every park in this country, great and small, has suffered from the causes which are now threatening Prospect Park, and every park must inevitably suffer from the same causes, until public interest and public intelligence is so educated in these matters that the prevalent conception of the responsibilities of Park Commissioners shall be much more serious and enlightened than it is at the present time.

The Artistic Aspect of Trees. I.—Form.

MANY persons profess themselves lovers of trees and find much real delight in shadowy forests, varied plantations, and well-developed isolated specimens. Yet most of them would be surprised if they were asked whether they had ever studied the aspect of trees from the artistic standpoint, and very few give proof that they have held this standpoint even unconsciously to themselves. Nevertheless it is only by studying trees, whether con-

sciously or unconsciously, from the artistic point of view, that we can arrive at a realization of the peculiar character and beauty of one species as contrasted with others, or of the individuals of a single species when seen under different conditions. Only thus can we learn really to appreciate trees, though science may teach us how to understand them; and only when we really appreciate them can we thoroughly enjoy them or use them to the best advantage.

From the artistic point of view trees have three characteristics which may be separately considered—form, texture and color. It is of form only that we shall speak just now.

The first element in the form of a tree is its general outline, its contour, the silhouette it makes when relieved against the sky or against masses of trees of other kinds. The outline peculiar to a given species may vary a good deal, of course, in different individuals; but in all full-grown and well-grown individuals it will be so nearly the same that the typical shape of the species may often be expressed in a very simple diagram on paper. An isosceles triangle with a broad base, for instance, gives the typical outline of the Spruce; a similar figure, but with swelling sides, gives that of a freely developed Hemlock; the White Elm would fill a vase-like figure supported by a straight line for the stem, the Hickory an elongated oval, the Sugar Maple a much fuller oval, the White Birch a very long and slender oval, and the Oak a figure approaching more nearly to a circle. In other cases the form of the head is more irregular, as with the Silver Maple, for instance, the typical shape of which would require to be expressed in a diagram of broken outline. But even in such cases this shape may be easily imprinted upon the memory, and, once imprinted, the pleasure of looking upon a new specimen of the tree is greatly increased by one's knowledge of how nearly it coincides with, or how far it departs from, the typical form of the species to which it belongs.

But a tree's general outline is by no means the only thing which determines what an artist would call its form. Its structure is almost of more importance than its outline in determining this, as within comparatively narrow limits its structure does not vary, while its outline may be greatly affected by a hundred accidents of position and experience. The branches of a tree may droop as in the Spruce, or spread at right angles as in the Cedar of Lebanon, or sharply ascend as in the Lombardy Poplar, or weep as in the White Elm; and between these extremes almost as many variations in branch-direction will be found as there are kinds of trees to examine. Each variation gives a tree a different form, the peculiarities of which are increased, of course, by such other facts of structure as the greater or less number of branches giving greater or less density and uniformity of surface to the head. And each of these differences of form means a difference in the expression of a tree—a difference in the character of its beauty, and, therefore, of its appropriateness to a given situation. A tree of regular, formal outline has beauty of a sort wholly unlike that of a tree with an irregular, broken outline; and the same is true when we contrast one that has many main branches dividing again into many minor ones, and, therefore, a dense, compact head, with one that has fewer branches and a more open and broken surface.

The average size to which the trees of a given species are apt to grow is, of course, another element to be considered in studying tree-forms. This is so obvious a characteristic that even the least artistic eye will note it, the most thoughtless planter will take it somewhat into account. But if we may judge by the results we see all around us in places where an intelligent landscape gardener has not been employed, few persons pay any attention to other characteristics of form. As an English writer said not long ago, it is lamentable to see how even the most enthusiastic amateur lovers of trees ignore those considerations which are "the commonplaces of the landscape gardener." Mere chance or at most a thoughtless,

abstract preference for some kind of tree seems much more often to have determined planting than a clear realization of intrinsic characters accompanied by reflection with regard to the appropriateness of one character or another to a special spot. We have known a would-be planter to ask for Elms, and yet not know whether he wanted American White Elms, which would grow up into vase-like, drooping forms, or English Elms, which would assume shapes almost identical with the shapes of Oaks. If a single tree is wanted in a conspicuous position a Sugar Maple is chosen, perhaps, because Sugar Maples are known to be "good trees," although it would be less well in place with its roundish head than a Hickory with its taller, narrower shape, or a Hemlock, sweeping the grass with its branches. It is the same when trees are set in masses—little thought is given to the way in which their forms will contrast one with the other, and a distressing confusion results where pendulous Birches, spiry-topped Spruces, round and solid Horse-Chestnuts and straggling Silver Maples work in concord only in a single way—each to prevent the others from appearing well and to deprive the plantation as a whole of unity, grace and effective expression.

But even when facts of outline are borne in mind, facts of structure are constantly forgotten. Yet these are of particular importance when a tree is placed in isolation. Almost any kind of contour is agreeable in an isolated tree, but in certain situations it makes a vast difference whether the eye rests upon an almost unbroken surface, like that presented by the Horse-Chestnut until it has reached a great age, or upon a surface which an artist would call boldly and effectively "modeled"—a surface diversified by those alternations of light and shadow which give variety of form within the limits of the general contour.

Of course no rules can be laid down in writing with regard to the employment of trees of various forms. The only way to use them well is to know them well; and the only way to know them well is to study them long and carefully. With scarcely a possible exception to be found, nature plants her trees with an artistic eye; and by studying her methods we may learn how to form our own. From the methods of intelligent men we may also, of course, often learn the same lesson, while from those of the less intelligent, we may gain, if we examine them in the right way, at least the knowledge what not to do. Taste is the guide we need to help us, and taste means the cultivation of our own perceptive powers, not the learning of cut-and-dried æsthetic formulas.

A movement has been started to induce the Canadian Government to establish a forest-preserve about the headwaters of the Muskoka River, which flows into Lake Huron, and of several of the important streams which feed the Ottawa, and which rise in the same region, Island Lake, the head of the Muskoka, being not more than half a mile distant from Otter Slide Lake, from which springs the Petewawa, a feeder of the Ottawa. This is a picturesque and well-wooded country, abounding in lakes and streams and swamps, and still frequented by game and game-fish; it is, moreover, one of the most important in Ontario as a natural reservoir. The proposed reservation embraces a territory of 330,000 acres, exclusive of an area of about 60,000 acres more of water. What the promoters of this scheme desire is that the government should create a public forest and define its boundaries; and appoint a forester and assistants to take charge of it; and cut the timber as soon as ripe under proper rules and regulations. There can be no doubt that the preservation of a great forest area at the headwaters of such important streams would be an immensely advantageous and profitable investment for the Canadian Government, not only in the influence it would exert upon the water supply, but in increased and permanent lumber crops, which good man-

agement would insure. This is a matter which should appeal to all Canadians interested in the development of their country, and one which the people of the United States will watch with interest, as an example of what must be attempted in this country if our forests and streams are to escape the extermination which now threatens them on every side. It is proposed that the Ontario Reserve shall be known as the Algonkin Forest.

Foreign Correspondence.

London Letter.

The wealth of hardy tree and shrub bloom this season is marvelous, and as we are always seeking for causes in gardening we are inclined to attribute the profuse flower crop to the long period of hot and dry weather last summer, which naturally tended to ripen thoroughly the growth of open air vegetation. The charm of beauty of a richly planted English garden at this time of the year could not probably be rivaled in any other country, our moist climate being so exactly suited to the majority of trees and shrubs from temperate climes. A walk through the gardens at Kew just now, which contain representatives of nearly every known hardy tree and shrub, is a great pleasure. There you see more clearly now than at any other season the wealth of exotic growth from every temperate country. You see how largely we are indebted to the floras of China and Japan, of Chili and of other regions of South America, of Central Asia, and of southern and central Europe. But from no country have our gardens derived so much of their open air beauty as from the vast North American continent, which we might say has supplied us with fully two-thirds of our ornamental trees and shrubs. The list I jotted down at Kew a day or two ago of showy flowering trees and shrubs from North America would alone make beautiful a large garden. Its range of color, of size and habit of growth is so wide that one might plant an exclusively American garden in a most artistic way. The term American garden in England has long been a misnomer. It is commonly supposed that the comparatively few members of the Heath family, the genera *Azalea*, *Rhododendron*, *Kalmia*, *Ledum*, *Andromeda* and the rest of peat-loving plants, comprised all that is worth planting of American shrubs. Happily, however, Kew is showing the public by good culture many others that deserve higher popularity, and our nurserymen are growing wise and propagate the best things largely so as to render them easily obtainable. I note a few of the North American shrubs now in bloom, which are undeservedly neglected by landscape gardeners and other planters in England.

There is not a lovelier shrub than the Rocky Mountain Bramble (*Robus deliciosus*), and of late years it has proved itself perfectly hardy, though for a long time only grown against walls. It makes wide spreading bushes which now are lit up by a profusion of great saucer-shaped flowers of snowy whiteness like single Roses. The large nurseries are now getting good stocks of it. *Pyrus coronaria*, though such an old introduction, is rarely seen, though for the beauty of its flowers it has few rivals among ornamental Pears and Apples. Its profuse crop of large rose-colored, semi-double blossoms, deliciously fragrant, render it in bloom one of the finest of lawn trees. The new *Neviusia Alabamensis* is flowering abundantly against a warm wall at Kew. Though not a particularly showy shrub, it is elegant in bloom, the flowers being in tufted feathery clusters of a pale yellowish green. The Californian *Ribes speciosum*, called here the Fuchsia-flowered Currant, is a very beautiful shrub, particularly as a wall covering, though quite hardy enough as an open air bush. There is no *Ribes* like it that I know and the blossoms look uncommonly like those of some of the old Fuchsias. Very charming in many an English garden now is *Choisya ternata*, called the Mexican Orange Flower, the

blossom being so much like that of the Orange, though it lacks the perfume. It is not thoroughly hardy, but as a wall shrub is excellent, the more so because evergreen.

The Snowdrop tree (*Halesia tetrapera*) flowers timidly at Kew, but this is, I think, because the dry, sandy soil does not suit it. I imagine it would do better planted near the edge of a lake or stream in the same position as one would plant a Catalpa or Deciduous Cypress. It is extremely pretty in bloom, the name Snowdrop tree being most appropriate. One of the Viburnums (*V. prunifolium*), called, I think, Black Haw by Gray, is a showy shrub at Kew, the large, white flower-clusters being like that of *Laurestinus*. I consider it a good ornamental shrub. The American Judas tree (*Cercis Canadensis*) is poor compared with the European Judas tree (*C. Siliquastrum*), so that I will not attempt to extol its merits. *C. Chinensis* is also flowering side by side with the other two, but it is likewise inferior. The common Judas tree is one of the prettiest spring flowering trees we have, being now literally smothered with brisk bloom. Other American trees that help to make our lawns and shrubberies beautiful now are the Red Buckeye (*Æsculus rubicunda*), the Amelanchier, some of the Thorns (*Crataegus*), *Magnolia acuminata* and *M. Fraseri*, the latter being scarcely inferior to the noble *M. grandiflora* of the southern States. The glorious race of Hybrid Azaleas and Rhododendrons are scarcely at their best, being fully three weeks behind their usual date of flowering this year.

W. Goldring.

London, June 1st.

The New York Flower Mission.

THE eighteen years' work of the Flower Mission has demonstrated to those interested the usefulness of flowers among the sick, poor and degraded.

The New York Flower Mission was established three months after the one in Boston, which was founded by members of the congregation of Rev. Mr. Hays, in 1870. A Flower Mission in San Francisco, California, has been in operation several years, organized on plans sent from the New York Mission. Americans living in Japan, who were interested in the work here, have one in successful operation there. And now children of the Tokio Flower Mission, the children of high-class Japanese officials, in company with their little American and European cousins, go out to distribute among hospital patients the flowers that have a healing influence.

The mission was originally established to distribute flowers among the hospitals, but soon there were requests for nosegays from the Homes for the Aged, the Insane Asylums and from the sick and poor in tenements. And now nurses, bible-readers and all sorts of missionaries call at the Mission rooms for a basket of bouquets to give out at the dispensaries, or to carry to those in distress.

Flowers come in from all directions within a radius of a hundred miles of the city. They come from private gardens, from Sabbath-school societies, from guilds, and King's Daughters. They are carefully assorted and packed, and are brought free of cost by express companies. The room of the Mission is furnished by All Souls' Church, and the total expenses last season of the New York flower mission from May until November was but \$30.

The distribution of flowers takes place on Mondays and Thursdays, when the flower girls are anxiously awaited at the institutions and places where they are expected. There is an endeavor made to please the fancies of those in confinement by selecting for them flowers for which they have a preference. The blind choose the blossoms that are strongly perfumed, such as Lilacs, Tuberoses and Honeysuckles. Colored people prefer the gaudiest flowers, while children beg for wild flowers, fruit blossoms, Field Daisies and Sweet Clover.

Germans make requests for Geraniums, which they propagate; Peonies, Tradescantias and Ivy; strawberry boxes filled with growing Ferns give great delight to persons of this nationality, as do Pfingster blossoms. The French ask for Violets, Pansies and Mignonette.

Men have their share of the flowers taken to hospital patients. They are received by them with the same eagerness shown by women. Flowers are particularly requested when important operations are to take place, as they are known to give fortitude and hope. Their influence upon the insane has been so soothing, that the keepers of the

mad-house on Blackwell's Island made especial request last season that their annex for the raving patients should receive flowers as often as possible. Insane men were formerly neglected, but this year a particular request has been made that flowers be sent to them as well as to the women.

It has in many instances been shown, when slips and plants have been given to the poor in tenements, that they have awakened an interest and given healthful occupation to some intemperate member of the family, who has in this way been diverted from drink, and it appears that the love for flowers is a strong remedial force when mind or body is weakened or diseased.

The officers of the mission propose to extend their work through the winter season if they can enlist the aid of florists, to supply them with growing plants during the time when the cut flower distribution would be impracticable. They would give out cuttings and small plants from depots established in localities where the poorest people live. They would give printed instructions how to treat the plants and offer a prize for the best results with these plants in the spring. The wholesome effect of plant-culture, it is hoped, might work a beneficent influence in the homes of the vicious. It is proposed to give an exhibition for the benefit of the mission of the plants presented by it and grown in humble homes. In time this project will undoubtedly be carried out.

It has been observed that the poor Germans who beg for the "Flowers of the Fatherland," to grow in their windows, as reminders of home, show the most interest in their cultivation, and are the most successful growers. In the German hospital, the sick have dried their flower bunches and made paper bags to preserve them in. Those who are hopelessly ill have asked that their flowers be buried with them. In the day nurseries, the little toddlers forsake their toys for a flower, and betray extreme delight when one is given to them. It is said that flowers are better than monitors to keep the children in good order.

F. A. Benson.

Plant Notes.

Notes Upon Lilacs.

LILACS, especially many of the garden varieties of *Syringa vulgaris*, are met with wherever hardy shrubs are cultivated; but there are several species of the genus, which, although possessing ornamental qualities of the highest order, are rarely seen in gardens. It is proposed to figure from time to time a number of these in these columns when proper material can be obtained for the purpose, in order that they may become better known and their beauty appreciated.

The genus *Syringa* is composed of about a dozen species of shrubs or shrub-like trees distributed from southwestern Europe through central Asia and the Himalayas to Mongolia, northern China and Japan. They have opposite entire or rarely pinnately-divided, smooth or slightly pubescent, deciduous, or in one species persistent leaves, a terminal thyrus of small, generally fragrant, lilac or white, regular, monopetalous flowers, with a campanulate, irregularly dentate calyx; a corolla, with a long or short cylindrical tube and a four-lobed limb, revolute in the bud; two stamens inserted below the mouth of the tube, with short included, or subulate exserted, nearly extrorse anthers; an included style, with a slightly or deeply cleft stigma; a two-celled ovary, with two minute suspended ovules in each cell, a subterete oblong capsule flattened contrary to the narrow partition, two-valved, the valves almost conduplicate; and pendulous compressed seeds, with slightly winged margins, a thick membranaceous coat, fleshy albumen and flat cotyledons.

The species may be grouped as follows:

§ EUSYRINGA.

Tube of the corolla long; flowers purple.

* *Leaves green on both sides.*

1. *S. vulgaris*, L. Leaves smooth, long-petioled, cordate or ovate-cordate, contracted into a slender point; inflorescence often in pairs from the ends of the branches; calyx irregularly four-tubed, glandular puberulous; limb of the corolla concave, the lobes cymbiform; anthers included; fruit smooth, ovate.

Syringa vulgaris is a native of the mountainous region of central Europe from Piedmont to Hungary. It has been a favorite garden plant for three centuries, and has produced in cultivation a great number of varieties with more or less dense inflorescence, and with flowers varying from purplish red to pure white. Double-flowered and blotched-leaved varieties are cultivated. The leaves of this species and of all the varieties are often greatly disfigured in the United States during the summer and autumn months by the attack of a white mildew.

Syringa oblata (see illustration on this page) is not known in a wild state; it was first discovered by Fortune in a garden at Shanghai, and later by the Abbé David in gardens near Peking. Its perfect hardiness in this climate indicates its northern origin. *S. oblata* differs but slightly in botanical characters from some forms of *S. vulgaris*, a geographical variety of which, it should, perhaps, be considered, although, from a garden point of view, quite distinct. Here it flowers ten or twelve days earlier than the earliest varieties of *S. vulgaris*, and its thick leathery leaves, which are never attacked by mil-

Fig. 30.—*Syringa oblata*.

2. *S. oblata*, Lindl. Leaves broadly cordate or deltoid, sharply acuminate; thyrsus short and broad, often in pairs from the ends of the smooth or slightly puberulent branches; flowers large, appearing just before or with the unfolding of the leaves; calyx irregularly dentate, the teeth obtuse or subanceolate, the tube slightly glandular; lobes of the corolla round and flat; anthers included; fruit smooth-ovate, acute.

dew, turn in the autumn to a rich dark russet-red color, a character which should be taken advantage of by hybridizers to secure a new race of Lilacs with the large inflorescence of *S. vulgaris* and the foliage of this Chinese plant. *S. oblata* is a stout spreading shrub here, now eight or ten feet high, flowering profusely every year. There is a white-flowered variety, which has not flowered here.

3. *S. Chinensis*, Willd. Leaves ovate, acuminate, obtuse or rounded at the base or often contracted into the long,

slender petiole; calyx campanulate, irregularly four-toothed; tube of the corolla long and slender, the obtuse lobes of the limb spreading with inflexed margins, sometimes mucronate; anthers included; stigma two-lobed; fruit oblong, acuminate, smooth.

Syringa Chinensis, Willd. Berl. Baum., i. 48.

Lilac Varina, Dum. Cours. Bot. Cult., ii. 547.

S. Rothomagensis, Nouv. Duham., t. lviii.

S. dubia, Pers. Enchyr., i. 9.

S. correlata, A. Br. Sitz. Gesell. Nat. Berlin, 1873, 69.

This plant, although long cultivated, is not known in a wild state. It is believed to be of Chinese origin, and it is not uncommon in the gardens of Pekin. In general appearance, in the shape of the leaves, the size of the flowers and in the period of blooming, it is intermediate between *S. vulgaris* and *S. Persica*. This is one of the hardiest and handsomest shrubs in cultivation, producing its enormous rather lax clusters of flowers in the greatest profusion. There are varieties with rosy purple and with white flowers.

4. *S. Persica*, L. Leaves ovate, lanceolate, narrowed into an acute, sometimes mucronate point, entire or rarely pinnatifid, the base contracted into a slender petiole; thyrsus loose, the flowers spreading; calyx with four obtuse lobes; tube of the corolla long and slender, the ovate lobes with inflexed margins slightly spreading; anthers included; fruit linear, obtuse or apiculate, smooth.

Syringa Persica has long been an inhabitant of the gardens of Persia and India, whence it was introduced into Europe and America. Its native country, however, was long unknown until it was met with by Dr. Aitcheson, of the Afghan Boundary Survey, who found it "a very common shrub on the low and outer hills near Shalizan up to nearly 7,500 feet."* Varieties with lilac and with white flowers are common. *S. pteridifolia* is a variety in which the leaves are deeply lacinate.

* * Leaves pale on the under side.

5. *S. villosa*, Vahl. Young shoots smooth, slightly striate-angled, conspicuously marked with oblong white spots; leaves broadly ovate-lanceolate; contracted at the base into a short, stout, grooved petiole, and with scabrous margins and conspicuously reticulated veins, the pale under side, especially along the principal veins, covered with long, slender, scattered hairs; thyrsus elongated, narrow and often interrupted; calyx smooth or slightly pubescent, the short, obtuse lobes much shorter than the tube; tube of the pale, rose-colored corolla slender, four times the length of the calyx, the oblong lobes with strongly inflexed margins erect or spreading; stamens included.

Syringa villosa was discovered near Pekin about the middle of the last century by the French missionary, d'Incarville. It was found in the same region by David, and plants raised from seed sent to the Arnold Arboretum from Pekin by Dr. Bretschneider are now growing here. To this species should perhaps be referred, as M. Franchet hints in his paper upon the Chinese Lilacs, † *S. Fosikæa* and *S. Emodi*, which, as he points out, cannot be separated from d'Incarville's plant either by the shape of the leaves, the character of the inflorescence, or by the shape and size of the flowers. In the Himalaya plant (*S. Emodi*), however, the long, white hairs which cover the under side of the leaves of *S. villosa*, are replaced by a minute puberulence on the mid-rib, which is even less developed on the leaves of *S. Fosikæa*. The bark, color and markings of the young shoots and the habit of these three plants are identical, although in *S. Fosikæa* the leaves are narrower than in the Chinese plant, but not narrower than those of many Himalaya specimens. The plants of *S. Fosikæa*, now widely distributed in gardens, have all been propagated from a single plant discovered in a Hungarian garden, but not known to be wild in Europe, and probably of Asiatic origin.

6. *S. pubescens*, Turcz. Leaves ovate, three or four ribbed, cuneate at the base, one and a half to two inches long, pale-green above, pale below, the mid-rib distinctly pubescent; calyx smooth, with short, triangular, sometimes minutely mucronulate lobes; tube of the pale, rose-colored corolla very slender, six times longer than

the calyx; the lobes of the small limb short and oblong; fruit obliquely oblong, verrucose.

§ § SARCOCARPUM.

Leaves persistent.

7. *S. sempervirens*. Leaves coriaceous, short-petioled, ovate or suborbiculate, entire; cyme few-flowered; calyx cup-shaped, obscurely crenate; tube of the short corolla white, three times as long as the calyx. The lobes finally reflexed, thick, obtuse; anthers inserted in the middle of the tube; style slightly bifid; fruit drupaceous, with two cells; one abortive, the other containing at maturity a single, oblong, irregularly incurved seed.

Syringa sempervirens, Franchet, Bull. Soc. Linn., Paris, No. 77, p. 613, was discovered by the French missionary, the Abbé Delavey, at an elevation of 7,500 feet in the mountains above Tapintze in Yun-nan. It has not been introduced into cultivation.

§ § § LIGUSTRINA.

Tube of the corolla very short; flowers white.

8. *S. Amurensis*, Rup. Leaves ovate or oblong, obtuse or acuminate, contracted into a long, channeled petiole; thyrsus densely flowered; calyx sub-membranaceous, smooth, irregularly toothed; tube of the corolla included in the short calyx; the lobes obtuse; fruit oblong, obtuse, smooth.

Syringa Amurensis is a hardy shrub six or eight feet high, with white, fragrant flowers; a native of Manchuria.

9. *S. Pekinensis*, Rup. Leaves ovate or deltoid, obtuse or acuminate, rounded at the base or contracted into the long, slender, channeled petiole, dark green and opaque above, lighter on the under side; thyrsus densely flowered; calyx obscurely denticulate; tube of the white corolla barely longer than the calyx; fruit smooth, linear-oblong, acute, or slightly beaked at the end.

Syringa Pekinensis is a native of the mountains of northern China, where it was discovered by David. It is growing in the Arnold Arboretum, where it was raised from seed sent by Dr. Bretschneider from Pekin, but as yet has shown no disposition to flower. It is here a slender, tree-like shrub, perfectly hardy, and already ten to twelve feet high, with long, graceful, flexuous branches, covered with a smooth, yellow-brown bark, not very unlike that of a Cherry tree. A plant with distinctly weeping branches appeared among the seedlings raised in the Arboretum.

10. *S. Japonica*, Maxm. Leaves broadly ovate, acuminate, contracted into a sharp point, rounded or slightly cuneate at the base, smooth above, villous-pubescent on the under side; thyrsus many-flowered, calyx puberulous denticulate; tube of the corolla included in the calyx, the lobes thickened on the margins, apiculate; the smooth fruit oblong, obtuse.

Syringa Japonica is a native of Japan. It has been cultivated in the Arboretum for a number of years, where it makes a handsome small tree.

11. *S. rotundifolia*, Decne. Leaves orbicular, abruptly acuminate at the end, cordate or rounded at the base; panicle many-flowered; calyx membranaceous, slightly denticulate, tube of the corolla included in the calyx, the lobes ovate, obtuse.

Syringa rotundifolia, Decne., *Nouvelles Archives du Muséum*, ii, 44, is a native of south-eastern Manchuria, and has not yet been introduced into cultivation. C. S. S.

A Tropical Garden.

THERE was published in one of the early issues of GARDEN AND FOREST an illustration showing the entrance of what may be called, perhaps, a typical New England garden, or rather of a garden in which some of those forms of plant life typical of the vegetation of north-eastern North America—the White Pine, the Hemlock, the Oaks, Maples and the Hickories—are conspicuously displayed as Nature often groups them. Our illustration on page 223 of the present issue represents the entrance of a garden almost at the other extremity of the

* *Four Linn. Soc.*, xviii, 78.

† *Observations sur les Syringa du nord de la Chine*, Bull. Soc. Philomathique de Paris, July, 1885.

earth, and about as unlike a New England garden in the nature of the plants which adorn it as it is possible to imagine. It is the entrance to the Botanical Garden at Peradenia, near the famous city of Kandy, in the Island of Ceylon, where for seventy years the British Government has maintained one of the most important botanical establishments in the tropics. The Mahavelli River flows round the garden, which occupies a horseshoe-shaped peninsula among the mountains, and which on the land side is protected by impenetrable thickets of Bamboo. The climate is admirably adapted to insure the vigorous growth of tropical plants, which are found here of a vigor and size rarely attained in other tropical gardens. Peradenia differs widely in arrangement from most of the so-called botanical gardens of the world. The plants are not huddled

thirty buttresses, from which huge snake-like roots spread out over the surface of the ground for a distance of one or two hundred feet. It is the "Snake-tree" of the natives. The collection of Palms in this garden, from both the old and the new worlds, is very large, and not the least remarkable is the native Talipot Palm (*Corypha umbraculifera*), which, unfortunately, does not appear in our illustration. No other tree, perhaps, presents a more striking and remarkable spectacle than the Talipot when it shoots up its giant inflorescence high above the top of the mountain forests in which it grows. The trunk is perfectly straight and pure white, like a marble column, supporting at its summit, often one hundred and fifty feet from the ground, a crown of fan-shaped leaves, which, on fully grown specimens, have a surface of 150 to 200 square feet, and from which,

A Tropical Garden.—See page 222.

together in formal beds, but are grouped naturally through the garden, which is about one hundred and fifty acres in extent, and produces a broad, park-like effect. The great clumps of different species of Palms near the entrance will serve to indicate how the most important natural groups of plants are managed in this truly noble garden, and to show to our readers some of the beauties of tropical vegetation. The large tree, the top of which appears at the left of the picture above the Palm in the foreground, is the *Ficus elastica* or Rubber-plant, so commonly grown in this country as a small pot-plant for the decoration of living rooms. In its home in the tropics it attains the size of a noble forest tree, often a hundred feet in height, with an enormous leafy crown borne on branches spreading out horizontally forty or fifty feet from a ponderous stem, supported on twenty or

once in the life-time of the tree—generally when it is seventy or eighty years old—shoots up a pyramidal inflorescence thirty or forty feet in height, and covered with countless myriads of small yellow-white flowers. When the seed is ripe the tree dies. The "Ola" paper of the Cinghalese was made from the leaves of this tree; and all the old Paskala manuscripts in the Buddhist monasteries on the island were written with an iron stylus on paper made by boiling narrow strips of Talipot leaves. We shall hope on another occasion to illustrate some of the remarkable plants in the Peradenia garden.

"Everything made by man's hand has a form which must be beautiful or ugly: beautiful if it is in accord with nature and helps her; ugly if it is discordant with nature and thwarts her."

Cultural Department.

Celery.

THIS is probably the most important of all our garden crops.

It can be used every day in the year; from September till April as blanched Celery, and from May till August as green Celery for flavoring soups. An abundance of blanched Celery can be found in the New York and other city markets in July and August, but it is Kalamazoo and not Long Island Celery. We have tried hard enough to have good blanched Celery in summer, but have always failed, the crop being destroyed by rust. Why not grow it in moist land, as they do in Kalamazoo? We have tried that, and on the naturally moist or wettish land it has rusted far worse than in good, common garden soil.

The White Plume is a most excellent Celery for use from September till New Year's, and as it is self-blanching, and the blades, as well as the stalks of the inner leaves, become white, it has an uncommonly handsome appearance. Although it is said that this variety needs no earthing up, we find that banking lengthens the stalks and renders them much more tender. Golden Heart is a most excellent all-round variety, dwarf, and suitable for early or late crops. New Rose is much like London Red. The pink tinged Celeries are seldom esteemed as highly as the white ones, but they are the finest flavored and capital keepers. Boston Market, regarded so favorably around Boston, and there grown with all its sprouts, is not so great a favorite here. Its best characteristic is that it keeps well. In growing it but one head should be allowed and all the sprouts rubbed off at planting time and then again before the banking is begun. Henderson's Half Dwarf is an excellent sort for use before March, but does not keep later. The Golden Self-Blanching is after the style of White Plume, only yellow, and in no way to be preferred. The giant Celeries require too much room, are unwieldy to handle, are poor keepers, and their leaf stalks are often hollow.

Seed of Golden Heart sown in a flat in the green-house about the end of January, and the seedlings afterward pricked off into other flats and then into a cold-frame, are now planted out in rows three feet apart in the garden. These now furnish a good supply of leaves for flavoring. But they will be of no use for white Celery; if kept for this purpose most of them would run to flower and all would rust. A March sowing gives the earliest white Celery here. The main crop was sown April 26th in a well prepared out-door bed, and the seedlings are now up in their second leaf and fit for pricking off into beds. We never transplant directly from the seed bed, but first prick off the seedlings four to six inches apart into well prepared beds, there to remain till planting time. By this means well-rooted, stocky plants are secured. The main crops are planted out in July and as the ground is ready; sometimes it is August before the planting is over. Celery succeeds Marrow Peas, early Snap Beans, Potatoes, Cauliflower, Cabbage or Strawberries. For the crops we shall use before New Year's, we line off the ground in rows four and one-half feet apart and throw out the ground in the rows to a depth of six inches and to a width of ten inches. This gives us ample room for earthing up the crop, and the trenches are handy for holding manure and water. We manure broadcast for the spring crop and in the row for the Celery. Planting on the level has been tried here, but with indifferent success. For Celery to be used after New Year's we plant in the same way, but in rows only three feet apart; this is because the late crop should not be earthed up, except to "handle" it, before it is packed into trenches to keep through the winter.

One of the chief points to observe in growing Celery is that from the time it germinates till it is packed away for winter it should never suffer by drought.

In banking up Celery in fall some discretion should be used. Celery banked up in August whitens in three to four weeks, that banked up in September in four to six weeks, but that banked up in October will not whiten before New Year's, if then. Do not bank up Celery all at one time, but a little at a time, and never "handle," bank or store Celery when it is wet or damp, else rust or rot may overtake it. Celery to be used before Christmas should be banked in September, but avoid banking or handling late winter Celery before the beginning of October. September and October are the best growing months for Celery.

Our Celery is wintered in trenches on a warm, sunny slope. The Celery is in single rows, and the trenches are as deep as the Celery is long, the plants being packed up close against each other. Four of these rows, each nine inches distant from the other, are formed into a ridge in order to lead off the surface the

rains of winter. And to further keep them dry in winter, we cover them with boards. We also use salt hay and forest tree leaves to exclude hard frost from the ground. The Celery keeps in this way in these trenches till the spring thaws set in; then it is lifted out, all decaying matter cut off, and it is buried again, but this time above ground, with earth between the plants and shutters over them. Celery in plenty was kept in this way up till the 7th of May. But towards the end of April Celery weakens perceptibly.

Now, while these dates are an very well for Long Island, in less favorable localities Celery seed should be sown proportionately earlier.

It is a fact that Celery is often spoiled in preparing it for use, by washing it. In order to have Celery in its finest condition, as regards crispness and flavor, it should not be washed or robbed of all its roots till immediately before it is prepared for table. Washing and dressing Celery before sending it to the kitchen or some two or three days before using it, as happens when it is sent to town, may make it look well, but it surely injures the flavor of the plant.

Glen Cove, L. I.

W. F.

Spathoglottis Kimballiana.—This is a handsome and very remarkable Orchid, very rare, and the finest of the genus. It is now in bloom with W. S. Kimball, Esq., of Rochester, N. Y., in whose honor the plant is named. It flowered for the first time in England some six weeks ago in the collection of Sir Trevor Lawrence, and has been awarded a first-class certificate by the Royal Horticultural Society of London. Its flowers are as large as *Phalænopsis grandiflora*, and of a very pleasing yellow color, being borne many together on a fine erect spike. It was discovered in 1886 by I. Forstermann in the Malayan Archipelago, who first (from a distance) thought it a yellow *Phalænopsis*, so great was the resemblance of the flowers to that species. It is sparingly found growing on rocks in a very moist situation.

Oncidium pulvinatum.—This fine Oncidium, introduced many years ago, is now rarely met with in collections, having been discarded of late years by cultivators, owing to its cultural requirements not being successfully carried out. A grand specimen in fine health is now flowering in the well kept collection of H. Graves, Esq., Orange, N. J. It has four stout, many-branched spikes densely laden with upwards of 1,200 flowers, lip being of a fine bright yellow, the sepals and petals beautifully marked with dull chocolate. Pot culture and intermediate house temperature suit this species admirably, with a good supply of water during active growth.

June Notes from the Flower Garden.

DOUBLE-FLOWERED herbaceous Pæonies find a place, and generally a prominent one, in all old country gardens, where they spring up and flower and die down year after year. Single-flowered Pæonies, although much more beautiful, are less often seen, and gardeners in this country are only just beginning to appreciate them and to realize that among them are some of the very finest of all hardy herbaceous plants. Nearly two dozen species or sub-species of Pæony are known, natives of southern Europe, northern and western Asia and western North America; of these all but one are herbaceous. Many of the species have long been cultivated, especially *P. albiflora*, a Siberian plant, and *P. officinalis*, from southern Europe, and they have given rise to numberless varieties, both single and double flowered, and with petals varying from pure white or pale pink to deep scarlet. Many of the species have probably never been cultivated in this country, and no one has yet made here anything like a complete or even a representative collection of the best garden varieties. Such a collection, could it be properly studied and correctly named, would be of great service to gardeners, and would well repay systematic study. Certainly there is no class of hardy plants of so much beauty which are so inadequately known in this country. The most beautiful single-flowered Pæony here, in a very small and badly-selected collection, is *P. albiflora*, with deliciously fragrant, pure white satiny flowers, four or five inches across, two or three being produced sometimes from the same stem. Vesta, a seedling, raised evidently from the last, has immense pale pink flowers, shaded delicately with rose, and when fully expanded ten or twelve inches across. Abyla has smooth, rosy pink flowers, three inches across, and is a less desirable plant than Galopen, with much larger pink flowers, but not otherwise distinguishable from it. Algeria has dark purple-red, satiny flowers, and Gordens, very handsome, large, spreading, dark purple-red

flowers. *Ranunculiflora* was in bloom ten days earlier than any of these; it is a form no doubt of *P. officinalis*, with rosy red, not very large nor distinct flowers. I do not pretend to vouch for these names, which are those under which the plants were imported from Europe.

The showiest herbaceous plant just now in flower in the gardens in this neighborhood is a very fine variety of the Caucasian Poppy (*Papaver bracteatum*), raised several years ago by Mr. Francis Parkman, in which the flowers are large—seven or eight inches across, deep blood-red, and handsomely marked on the inside of the petals with a dark purple-black eye. It is a very hardy plant, which, when once fairly established, spreads into a broad mass, from which the stout, naked scapes rise to a height of two to three feet. This Poppy rarely produces seeds; and is propagated by root cuttings, taken in the summer, before the plants begin their second or autumn growth. The young plants are best grown in pots, until they have attained considerable size, and then, as they transplant badly, they should be planted without disturbing the roots where they are to remain permanently.

Vincitoxicum acuminatum is a Japanese plant, with twining stems two or three feet long, softly pubescent, long green leaves, and loose axillary, long-stalked clusters of pure white star-shaped flowers, which it continues to produce during several months. It is rather an interesting addition to the list of hardy summer-flowering perennials.

Gillenia trifoliata, the Bowman's Root of southern woods, is an excellent plant in the herbaceous border, where it makes a wide, graceful mass of slender red stems, two or three feet high, covered with light, three-lobed leaves, and many pretty white-petaled flowers in loose panicles from the ends of the branches.

Allium caruleum, a Russian species, is a good border or rock-garden plant, with showy, compact heads of bright blue flowers, which, individually, are not large. It is perfectly hardy, and well worth cultivating for the peculiar color of the flowers. Another Onion (*Allium Moly*), a native of southern Europe, and a very old garden favorite, still holds its own among all the more recent introductions of this family. A mass of this plant, when the bright yellow flowers, which appear in compact umbels above the broad leaves, are open, is always a pleasant sight, which year after year will be renewed without care or trouble.

Vancouveria hexandra is a low herb, belonging to the Barberry family, and a native of the North-west coast, where it inhabits the moist, shady Coniferous forests. It takes kindly to cultivation here, and has now spread over a considerable space among the rocks in the shadiest part of the rock-garden, where now it is throwing up in great profusion its tall, naked, slender flower scapes. They are often two feet high, and bear near the summit a number of small, white, nodding flowers on long, slender, filiform, drooping pedicels. The thin, pale green leaves are composed of two or three stalked, obtusely-lobed leaflets, which possess in themselves no little beauty.

But the handsomest flower in the garden, and one of the handsomest of which the North American flora can boast, is the great red and white Lady's Slipper (*Cypripedium spectabile*). It is not a rare plant at all in Northern bogs, and one of the easiest of all the terrestrial Orchids to cultivate, either in the open border or in a pot, but no other *Cypripedium* can compare with it in beauty, and it quite puts to shame all the high-priced tropical species and the innumerable and never-ending garden hybrids which Orchid-growers now produce so easily. *Cypripedium spectabile* is a downy plant, with leafy stems, a couple of feet high, bearing one or several pure white flowers, with an inflated, prominent, rosy-purple lip. There is not a garden which cannot be made more attractive by bringing into it this charming plant.

Boston, June 20th.

C.

Notes from the Arnold Arboretum.

THE Rocky Mountain Raspberry (*Rubus deliciosus*), although one of the first of the central and southern Rocky Mountain plants known to botanists, having been discovered in 1820 by Dr. James, the surgeon of Long's expedition, has only been in cultivation a few years, comparatively, and is still very little known in gardens. It is one of the handsomest and hardiest of the early summer-blooming shrubs. Like the well known *Rubus odoratus* and *R. Nutkanus*, it has simple leaves and large flowers. *R. deliciosus* has erect, arching, graceful stems four or five feet high, covered with light brown or gray striated bark. The bright green leaves are borne on slender red petioles one and a half or two inches long. They are two inches or more in diameter, reniform-orbicular, rugose, three to five lobed,

sharply serrate, tomentose pubescent when young like the calyx and the young shoots, which are also red. The erect, few, generally one-flowered peduncles, are long and slender. The flowers, when expanded, are nearly two inches across, and pure white. They resemble miniature Cherokee Roses, and present a charming appearance when they cover the arching branches of the plant. The fruit is small, composed of three or four dry, tasteless carpels; and the delicious flavor, to which the plant owes its name, was developed doubtless in the imagination of the hungry botanist who discovered it. This plant may be easily raised from seed, which is produced here, but not very abundantly, or by cuttings; it is perfectly hardy, and will thrive in any exposure and in any good soil. Stronger shoots and better flowering wood are obtained by cutting out the old stems after they have finished flowering, thus stimulating the growth of vigorous young wood.

The Nine-Bark (*Physocarpus*, or, as it is more generally known, *Spiraea opulifolia*) is a familiar plant in the gardens and along the borders of woods and streams in the Northern States. It will not be in flower here for two or three weeks yet, although its near relative from another continent, *Physocarpus Amurensis* of Manchuria, where it was discovered in 1856 by Maximowicz in the mountains along the Amoor River, has been flowering here for several days. It is a large shrub, with stout erect branches, six or eight feet high, covered, like those of its American congener, near the base with loose bark, separating into numerous thin layers. The ample leaves are broadly acuminate, three to five lobed, and sharply serrate. The large, white, long-pedicel flowers, three-fourths of an inch across, with conspicuous purple anthers, are borne in rather loose subracemose corymbs, terminal on lateral red, leafy young branches, produced in great profusion from the stems of the previous year. The Manchurian Nine-Bark is a very hardy, free-growing shrub, rather coarse in appearance and habit, but well suited to grow in the shade or to produce bold, effective masses of foliage in large shrubberies or on rocky banks.

Among *Spiræas*, two species now in bloom in the Arboretum, *Spiraea alpina* and *S. cana*, are rarely seen in gardens here, although possessing very considerable merit as ornamental plants. *S. alpina*, like *S. Thunbergii* and *S. prunifolia*, belongs to the section of the genus in which the corymbs of flowers are produced from the ends of very short lateral branches. It is a graceful plant, three or four feet high, with slender, arching, flexuous, angled stems and linear-lanceolate leaves which are sharply acuminate, pale green, entire or sometimes sharply serrate towards the apex. The handsome corymbs of white flowers are produced in great profusion, and in size and general appearance are not unlike those of the well-known *S. Cantonensis* (*Reevesiana*), in which, however, the inflorescence appears at the end of long lateral branches. *S. alpina* is a native of the mountains of Siberia and Mongolia. It is very hardy here and soon grows into a handsome specimen. *S. cana* is a very variable species with erect, round, pubescent branches, growing here to a height of from three to four feet. The leaves are elliptical, silky, villous on the lower side, entire or sometimes with three or four sharp teeth at the end; the small, many-flowered corymbs are borne at the end of long leafy branches of the current year. It is a native of Croatia and Dalmatia. *S. Sauranica*, a larger and less pubescent plant and not rare in gardens, is considered a variety of this plant.

Among the early *Viburnums* in flower is *V. dilatatum*, a common Japanese plant not uncommon also in central China. Here it is a low, wide-branching shrub, now three or four feet high, with rigid spreading branches, covered with very dark gray bark; handsome ovate or obovate leaves three or four inches long, rounded or sometimes abruptly acuminate at the end, sharply and conspicuously serrate above the middle, otherwise quite entire; bright yellow-green above, paler on the under side, with very prominent mid-rib and primary veins. The under side of the leaves, especially along the veins, petioles and young shoots, are densely covered with short white tomentum. The small, creamy white flowers are produced in a wide, open-branched, long-stalked cyme, from the end of short, leafy branches. The orbicular-ovate fruit, which is not produced here very abundantly, is scarlet. This is a very hardy plant, not showy in flower, but worth cultivating for its handsome foliage, which, when bruised, has, as does the wood, an exceedingly strong and disagreeable odor.

Viburnum pubescens, although rarely seen in gardens, is an exceedingly beautiful species in cultivation. It is a compact shrub, two or three feet high, with rigid, erect branches and ovate, taper pointed leaves, remotely and sharply serrate, except near the base, conspicuously pinnately veined, the under side, as well as the young shoots and very short petioles, soft

pubescent; the flat cymes of small, white flowers, which, in cultivation, are produced in the greatest abundance, appear at the ends of the young branches. The fruit is dark purple or nearly black. *Viburnum pubescens* is found along the borders of woods from western Vermont to Wisconsin, extending south to New Jersey and Kentucky. It is very hardy and flourishes in good garden soil. Like so many North American shrubs, it has been too much neglected as a garden plant.

And this is true as well of the Sheep-berry, *Viburnum Lentago*, a very handsome, small tree, or tree-like shrub, which sometimes attains a height of twenty-five or thirty feet, with a clear, straight trunk, supporting a round compact mass of foliage. It has large ovate, sharply pointed leaves, three or four inches long, closely and sharply serrate, and borne on long margined petioles, which, like the buds, are covered with brown scurf. The broad flat cymes, four or five inches across, of small, creamy white flowers, are sessile. The black, oval fruit, half an inch long, ripens in the late autumn, and has an agreeable, but rather insipid flavor. The wood of this species has a most disagreeable odor. *Viburnum Lentago* is a common northern plant, widely and generally distributed from the shores of Hudson Bay to Georgia and Missouri, attaining its best development far north, and found generally in deep, rich soil, along the borders of swamps or streams, or on high rocky ridges. The compact habit of this plant, its handsome foliage and showy clusters of flowers, entitle it to general cultivation.

Viburnum macrocephalum, of which the form with all the flowers sterile only is known, is not often seen here. It was discovered by Robert Fortune in gardens at Shanghai and Chusan, and has always been rather a favorite plant in England. Here it is perfectly hardy and flowers every year, although it does not grow with any vigor, or produce its cymes of pure white flowers, which are generally mistaken for those of a white-flowered *Hydrangea hortensis* in much profusion. It is a low shrub, with rigid, wide-spreading branches, covered with smooth, light gray bark, and rather small, pale, oval leaves, with small remote teeth, and covered on the under side with stellate pubescence. It is usually grafted on *Viburnum Lantana*, and must then be constantly watched to prevent the stock from sending up suckers, which rob the plant of what little vitality it possesses here.

Among plants of recent introduction of the very first class, from an ornamental point of view, must be mentioned *Lonicera Alberti*, a dwarf Honeysuckle, discovered a few years ago by Dr. Albert Regel in the high mountains of eastern Turkestan. It is one of the Bush Honeysuckles, and is a low, smooth plant, with long, slender, spreading, pendulous branches, which only rise a foot or two from the ground, but soon make a wide, graceful mass of light green foliage. The leaves are deciduous, opposite, glaucous, linear oblong, obtuse, entire, or with one or two teeth near the base, from an inch to an inch and a half long, and are borne on short petioles. The fragrant flowers are produced in pairs on short axillary peduncles; the cylindrical tube of the rosy lilac corolla is four times longer than the calyx, with a spreading limb of five nearly equal, ovate-elliptical lobes, about three-quarters of an inch across when expanded. *Lonicera Alberti* is a perfectly hardy plant of easy cultivation; it is admirably suited for the margins of shrub beds, where its graceful branches can spread out over the turf, for the rock-garden, or for covering rocky banks.

Lonicera Maximowiczii is another handsome Bush Honeysuckle now in flower. It is a native of the mountain forests of eastern Manchuria. Here it makes a neat bush, with upright branches three or four feet high, covered with pale gray bark. The leaves are light green and shining above, paler on the lower side, which is covered with long, slender hairs; they are an inch and a half or two inches long, and hardly exceed the slender peduncles, which bear two bright, rose-colored flowers, the limb deeply two-parted, the upper division three-lobed. This is a very hardy plant, worth a place in a large collection of shrubs. ♀.

June 15th.

The Forest.

The Forest Vegetation of North Mexico.—V.

TURNING away at last from Chihuahua and the region stretching along the line of the railroad far northward and still farther to the south—a region made familiar by two seasons of diligent searching out its scanty vegetation over wide and weary desert areas of mountain and

plain—a region rich only in the matchless tints of its landscape and the floods of white sunlight overspreading all—we set out joyfully for a fresh field amidst the western Sierra Madre.

Following the route of Wislizenus, the early explorer, on his involuntary journey from Chihuahua to Cusihuiriacic, as nearly as a wagon road can follow a bridle trail in its devious course over the mountains and through their cañons, we cross three chains of mountains with intervening plains or valleys of such character and bearing such forest vegetation as has been described. Beyond Carretas our road mounts a high mesa, whose marginal bluffs are covered with an open growth of low Oaks and Junipers of the species already mentioned. The gullies, which cut into the mesa from every side, are occupied by the same growth, and from the gullies the trees scatter out over the adjacent mesa for a short distance; but they appear to have been unable to gain a foothold on the central area of the mesa. Some ten miles further on, however, where the mesa, gradually ascending, terminates in a broad ridge, its summit, as well as its slopes, is covered with a thin forest. Here, then, in our journey up to the mountains we have reached, at an elevation of 6,000 feet, the timber line. Descending from the mesa by a steep and tortuous grade, our road enters a wooded cañon of a pine covered range, and winding up through it, crossing its swollen stream thirty times in a distance of seven or eight miles, threading its narrow intervalles and clambering over its frightful ledges, brings us after a journey of seventy-five miles to the old mining town of Cusihuiriacic, noted among botanists as being the place where Wislizenus was held prisoner of state, as he styled it, from Sept. 13th, 1846, till the 3d of March following, restrained during most of that time within limits five miles from the town.

La Bufa towers over the cañon, through which straggles the town, a sharp peak whose summit is little less than 8,000 feet elevation, the highest point of the divide within view. Southward the divide lies amongst a broad belt of mountains, confused and abrupt upheavels of porphyritic rock, covered with forests of Conifers and Evergreen Oaks, which to eyes grown weary of the bare ranges to the eastward, seem luxuriant. As the slopes of the Bufa and the hillsides of its immediate vicinity have doubtless suffered deforestation from an early day, to supply the needs of the town and its mining furnaces founded in the beginning of the eighteenth century, it is probable that Wislizenus, who had no time for collecting on his forced ride from Chihuahua, in those forests first made the acquaintance of *Pinus strobiformis*, *P. Engelmannii* and *P. Chihuahuana*, three species published by Engelmann in Wislizenus' Report of his Mexican journey. The Arbutus mentioned by Engelmann in connection with these Pines nearly answers the description of *A. petiolaris*, HBK.; the Juniper may be either *J. occidentalis*, Hook., var. *conjugans*, Engelm., or *J. pachyphloea*, Torr., both of which are of common occurrence in this district; and the dwarf Evergreen Oak is perhaps *Quercus oblongifolia*, Torr.; but the mention of a *Thuya* must have been an error. That Wislizenus should not have secured specimens of *Quercus hypoleuca*, Engelm., *Q. grisea*, Leibm., and *Q. fulva*, Leibm., even on the Bufa common with small specimens of several of the above, surprised me; as did the finding, during my stay of five days in that vicinity, of more than a score of herbaceous plants, which have remained undescribed until recent years. But this shows the unfavorable circumstances, lamented by Wislizenus, under which his remarkable collection was gathered.

Northward from the Bufa for a few miles the divide is but a broad swell connecting two great plains, which are more widely separated farther north, where the divide rises again to an altitude of perhaps 9,000 feet. The plain lying east of the divide sweeps down beyond the horizon to the laguna of the deserts near the Rio Grande; that to the west, twenty or thirty miles wide and one hundred and fifty long north and south, rimmed on one side by the divide and on

the other by the Cordilleras, is the great basin of the Papi-gochic, or upper Yaqui. Fifty miles away in the north-west, looking across this plain and beyond a blue mountain chain which it bears, we see a lofty crest of the Cordilleras, which is the goal of our journey.

C. G. Pringle.

Correspondence.

To the Editor of GARDEN AND FOREST :

Sir.—I am a little surprised in reading the interesting notes on the Ginkgo tree in your last number that no mention is made of the specimen on Boston Common, which has a historical interest worthy of record. It formerly stood in the grounds of Gardiner Greene, Esq., on what was then Pemberton Hill, now Pemberton Square. After his death the estate was sold, and a condition of the sale was that this tree should be preserved, as there was then but one other in the country, which was the one you allude to as planted by Dr. Hosack. I remember perfectly seeing the tree on its way to the Common in 1834, or perhaps 1833. It was then some thirty feet high, and was transported on a low four-wheeled truck built for the purpose, and was planted on the Beacon Street Mall, directly opposite the house at the corner of Joy Street, to which Mrs. Greene had removed from Pemberton Hill.

Its removal was a subject of general interest at the time, as the papers announced that it was a very rare tree from Japan, a region almost as little known to us then as the moon.

It still lives and thrives, and its site has been rendered classic by the pen of the "Autocrat," as it is the starting point from the Beacon Street Mall of the "Long Path," to which he makes such touching allusion.

There are some fine specimens of the Ginkgo in Providence; but when I last saw them, five or six years since, they still preserved the stiff habit you describe, though they were some fifty feet in height.

Minneapolis, June 8th.

H. W. S. Cleveland.

[The old Ginkgo on Boston Common is well known to many of the older inhabitants of that city. It is now not more than forty feet high, and is not a large or a fine tree for its age, having perhaps never entirely recovered from the effects of the removal; it has for many years been crowded and overshadowed by neighboring Elms, and many of its branches are dead or dying. It has never taken on the graceful habit which this tree assumes at maturity when growing under favorable conditions.—Ed.]

New York, June 18th, 1888.

To the Editor of GARDEN AND FOREST :

Sir.—I have noted with interest the remarks of "Phylodendron," in your issue of June 11th, on the conditions of the Norway Spruces in Central Park.

About a year ago the authorities of the park became alive to the necessity of removing dying, deformed or crowded trees, and since that time 6,215 trees of this objectionable character have been cut down. Of this number 760 have been Norway Spruces.

The effects of this work may be seen along the west drive of the park, and particularly on Fifth Avenue, between Sixty-fifth Street and Seventy-second Street. In many places no replanting has been found necessary, as the original growth was sufficiently dense to allow a considerable margin for thinning-out. In other places, such as the bank on Fifth Avenue, just referred to, a new plantation has been established, consisting of shrubs and trees such as *Spiræa opulifolia*, *Philadelphus grandiflorus*, *Lonicera fragrantissima*, *Cornus sanguinea*, *Viburnum dentatum*, *Betula alba*, *Pinus Strobus*, *Pinus Mugho*, *Picea orientalis*, *Pseudotsuga Douglasii*, etc.

The park authorities have frequently been criticised for the radical cutting-out thus undertaken, and it has been thought best to remove the least healthy trees first and cultivate intelligent public-sentiment in regard to this cutting by managing it in such a way as to prevent a striking appearance anywhere of denudation.

Several large groups of diseased Norway Spruces are marked for removal during this summer and autumn, and by another spring I think there will be few of these objectionable Spruces left in the park.

SAM. PARSONS, JR., Superintendent of Parks.

Periodical Literature.

Harper's Magazine for July contains an article by Mr. F. H. Spearman called "The Great American Desert," describing those districts, formerly known by this name, which are now largely under cultivation and furnish support to a rapidly growing and prosperous population. It differs from many articles on the newer regions of the Great West we have read in being sensible as well as emphatic—in being neither a pessimistic tourist's chronicle, nor a panegyric concocted in the interests of land schemers, railroads, or the "boomers" of embryo cities. One paragraph we are glad to quote as reinforcing opinions already voiced in the editorial columns of GARDEN AND FOREST. After speaking of the way in which the great vexed question of the rainfall has been discussed by "experts who know absolutely nothing about the actual facts in the case," and by residents who are eager to explain the increase in rainfall, they assume, by all sorts of ridiculous reasons, Mr. Spearman shows how no perceptible increase in the amount of rainfall need be assumed to account for the increased humidity of the soil. "It is certain," he says, "that the buffalo grass sod which has covered these plains for centuries has become as impervious to water as a cowboy's slicker. Hence the rain never penetrates it, but rushes off the 'divides' in a fury to reach the rivers. Any one who has seen it rain on the plains can understand something of the deluge which covers the entire prairie to the depth of twelve to twenty-four inches during summer showers. It is easy to comprehend then how the numerous cañons in Kansas and Nebraska are cut by the eagerness of the flood to roll eastward. But when the prairie sod has once been plowed, the soil absorbs water like a sponge. After a day's heavy rain there is no mud visible in a plowed field; the moisture soaks downward to great depths, and the soil retains it through weeks of dry weather afterward, sustaining its crops without additional rain for a wonderful length of time. It is at least reasonable to suppose that under this changed condition of large portions of the soil, which now absorbs rain instead of shedding it like a rubber coat, the climate retains its atmospheric moisture better, and the rainfall becomes more regular, less falling at a time, but falling oftener. This change may account, too, for the heavy dews which of late years have been remarked in this country—a thing absolutely unknown ten years ago. The upturned soil parting with but a little of its moisture every day, it returns to it at night, well nigh as refreshing as a shower."

One of the illustrations which accompany Mr. Spearman's article shows a rude rustic bridge, built of logs, and, apparently, ropes, which is most interesting in the way it reproduces the construction of the vast bridge of stone and iron that stretches between New York and Brooklyn.

In Mr. Chas. Dudley Warner's "Studies of the Great West," in the same number of *Harper*, he speaks of the Central Hospital for the Insane of the State of Illinois as having "a large conservatory of plants and flowers," which is "rightly regarded as a remedial agency in the treatment of the patients." His description of the plan of Indianapolis, which its inhabitants are fond of calling the "Park City," is interesting.

A third noteworthy article in this magazine is one by Mr. Peter Henderson on the "Street Trees of Washington."

Recent Plant Portraits.

Botanical Magazine, May.—DENDROBIUM CLAVATUM, *t.* 6993; a magnificent species with large, orange colored flowers nearly three inches in diameter across the sepals, which, as well as the much larger orbicular petals, are spreading; the uniform or almost circular limb of the lip deep purple, margined with golden yellow. It has tufted, pendulous stems, two or three feet long, and short, broad, elliptical leaves. Although long known to botanists and one of the earliest discovered of the golden flowered Indian Dendrobies, this plant is here first figured in all its great beauty. It must not be confounded with Roxburgh's plant of the same name—the *D. sulcatum* of Lindley, a much more common species.

ALLIUM SUWOROWI, *t.* 6994, a tall, handsome species from central Asia, where it was discovered by Dr. Albert Regel on the Kirghis desert and near Bokhara. The tall, stout scape springing from a basal rosette of glaucous-green leaves, bears a large, long handsome, dense umbel of dark mauve-colored flowers.

ALPENIA OFFICINARUM, *t.* 6995; "the subject of this plate, the 'lesser or Chinese Galangal,' was formerly in great repute as

an aromatic stimulant amongst the Arabs and Greeks, and formerly in western Europe, but is now banished from the British Pharmacopœias. The plant that produced it was unknown to botanists till 1867, when Mr. Sampson, accompanied by that excellent botanist, the late Dr. Hance, of China, discovered it near the village of Tung-sai, on the peninsula of Lei-chan-fu, opposite the Island of Hainan itself." Its nearest affinity is the well-known *A. culcurita*, and Sir Joseph Hooker is inclined to believe it to be referable to that plant.

DOUGLASIA LÆVIGATA, *t.* 6996, an alpine plant from the mountains of Oregon.

PASSIFLORA VIOLACEA, *t.* 6997; a free blooming, green-house climber, believed to be a native of Rio Janeiro. It has three-lobed leaves and handsome lilac flowers, on solitary, slender peduncles, six to eight inches long, upcurved toward the end.

RHODODENDRUM ARGENTUM.—*Revue Horticole*, May 1.

CHRYSANTHEMUM BARON D'AVÈNE and C. JULES BARIGNY.—*Revue Horticole*, May 1. Two new varieties raised by M. T. Délaux, the first a cup-shaped flower with rose-violet petals, those in the centre much lighter, almost white; the second of the Japanese class, with narrow rose-colored petals.

SALIX BALSAMIFERA, Figs. 1-5, *forma typica*; Fig. 6, var. *vegeta*; Fig. 7, var. *lanceolata*; Fig. 8, var. *alpestris*.—*Bulletin Torrey Botanical Club*, May.

THE GERMAN PRUNE.—*Canadian Horticulturist*, May. One of the most generally cultivated fruits of central Europe—the German Prune—has been found to give excellent results in some parts of Canada, where its more general cultivation is now recommended.

ERYTHRONIUM GRANDIFLORUM, var. ALBIFLORUM.—*Gardener's Chronicle*, May 5. A little known, but very handsome plant, of Oregon and Washington Territory.

VITIS PTEROPHORA, *Gartenflora*, May 15th.—A handsome Brazilian species, with green and red leafy branches, from which descend remarkable red cordy branches, forming at their extremities, where they can reach the water, great masses of rootlets like the tail of a horse. The branches produce from their extremities at the end of the season of growth elongated tubers, formed by the lengthening and swelling of a sub-terminal internode. These tubers are five or six inches long, green and fleshy. They finally drop off, and reaching the ground produce, under favorable conditions, new plants. The tendrils of this plant are equally curious. They are slender and forked, and provided at the end of each fork with an adhesive disk. When the tendrils reach a support the disks adhere to it and greatly enlarge; and if the support will admit of it the tendril will embrace it, secreting from its surface a viscid tissue which glues it fast to the supporting surface. The flowers are green and inconspicuous. There is an earlier figure of this plant in the *Botanical Magazine*, *t.* 6803; and it has been figured in the *Gardener's Chronicle* as *Vitis Gongyloides*.

Notes.

The Second Annual Session of the Texas State Horticultural Society was held at Denison, Texas, last week.

According to European dispatches to the daily press, immense tracts of forest land in Sweden have been recently swept by fire. The town of Sundsvall, on the Gulf of Bothnia, is said to have been almost entirely destroyed by the flames.

The Rose and Strawberry Exhibition of the Massachusetts Horticultural Society was held at Boston on the 26th and 27th of June. The exhibition of Strawberries was finer than it has ever been before. The Roses, on the other hand, although shown in great abundance, were somewhat inferior in quality to those of last year. A nice feature was a collection of forty or fifty species and varieties of single Roses, for which there seems to be a growing appreciation. Besides Orchids and a generous display of cut flowers, there was a good collection of flowering shrubs, the most attractive of which was an *Andromeda speciosa*. A noteworthy plant was a faultless specimen of *Rhynchospermum jasminoides*, which was over six feet high.

The passion for Orchids is developing in Germany, although more slowly than in England and France. A large number of the plates published in the various German horticultural papers are now devoted to representations of new or rare Orchids, and although previous auction sales had been so unsuccessful that for two years none had been held in the empire, one recently organized in Berlin by an English firm, amid many predictions of failure, proved entirely satisfactory. The trade were large buyers and many new-fledged amateurs made very extensive purchases.

The official programme for the horticultural section of the Paris International Exhibition of 1889 was issued in January. There is to be a permanent exhibition, lasting from May 6th to October 31st, accompanied by eleven special exhibitions of five or six days each. Some of these last are to be open to all classes of exhibits pertaining to the section of horticulture, while others are to be more restricted in character. All exhibitors who desired to make plantings this spring were to send in their applications before the 11th of February last, but for those who desire to plant next spring the lists will be open until February 1st, 1889.

The State appropriation for the expenses during the current year of the Department of Parks and Gardens in the City of Berlin amounts to 159,278 marks—about \$40,000.

The official report of the wine production of France during the year 1887 shows a total result of 24,333,264 hectolitres. This is a falling off of three and one-half million hectolitres as against the year 1886, and is less than the average production of the last ten years taken together. The chief cause of decline is attributed to the increasing ravages of mildew and the Phylloxera, although certain western and southern departments had also to contend against disastrous weather. From Algiers, on the contrary, the report is encouraging, a notable increase being shown both in the extent of land planted with the vine and in the amount of wine produced. The cider harvest in France was also a good one, more than 5,000,000 hectolitres being produced in excess of the production of the year 1886.

Retail Flower Markets.

NEW YORK, June 29th.

The Rose crop of this locality has been demoralized by the protracted heat. Hybrids are small, colorless, and loose-petaled. American Beauties have been less affected, and La France are fine. A few Gen. Jacqueminots are arriving from Newport, and sell for from \$1.00 to \$1.50 a dozen. Marechal Neil Roses are scarce and small. They cost \$1.00 a dozen. Catherine Mermets continue poor and are 75 cts. to \$1.00 a dozen. Niphetos and Brides cost \$1.00 a dozen, and fine Mde. Cuisins the same. Perles and Souvenir d'un Ami bring from 75 cts. to \$1.00 a dozen. Hybrid Roses cost from 25 cts to 30 cts. each. Puritans bring from 15 to 25 cts. La France are \$1.50 and \$2.00 a dozen. Orchids cost 50 cts. a flower for Cattleyas, and 10 and 20 cts. a flower for Oncidiums. There are from 15 to 60 flowers on a spray of the latter species. Gladioluses are 10 and 15 cts. each. Peonies grow scarcer and bring 10 and 15 cts. each. Lily-of-the-Valley from Newport arrives in small lots. It is 75 cts. a dozen. Carnations bring from 35 to 50 cts. a dozen. Longiflorum Lilies and Callas cost 20 cts. each. Pea blossoms bring 25 cts. a dozen, and Heliotrope and Mignonette 50 cts. a bunch. The latter is very slender and ragged. Smilax costs 50 cts. a string and 40 cts. a yard. Field Daisies are 25 cts. a dozen. Moss Roses bring \$2.00 a dozen. They are so fully open that they can no longer be classed as "buds."

PHILADELPHIA, June 29th.

The very hot weather which prevailed during the latter end of last week seriously affected the flower trade, and, even during this week, which is somewhat cooler, the demand is very limited. Transient trade is done only in the early morning or late in the afternoon. Amongst Roses American Beauty is superior to any other. Prices for Roses vary very little from those reported in last issue—which may, in short, be stated from 50 cts. to \$3.00 per doz. Sweet Peas still continue to be in demand, at 25 cts. per doz. The Cornflower sells at the same price; the blue variety being most in demand. The only notable feature in novelties is in varieties of Coreopsis, which sells at 25 cts. per dozen. Water Lilies (*Nymphaea Odorata*) are plentiful and also cost 25 cts. per doz. Carnations are still obtainable at 25 cts. per doz. Smilax costs from 40 to 50 cts. per string. *Asparagus tenuissimus* is in fair demand at from 50 to 75 cts. per string. Ferns, especially *Adiantum cuneatum*, are often asked for and sell at from 25 to 35 cts. per doz.

BOSTON, June 29th.

There is very little to be said about the cut flower market at the present time. Out-door Roses are just at their height and crowd everything else to the wall. On the street corners everywhere one sees great banks of Jacqueminots, Luizets and Hybrids in variety which are offered at five for 10 cts. Indoor Roses are very poor. The growers do not make any effort to produce good Roses under glass now, and many of them have cleaned out their houses and planted their young stock for next season's business. White Roses are still in demand, but there is nothing of the kind in the market worth buying. Carnations are abundant, cheap, but of inferior quality. Pink Pond Lilies sell well at \$3.00 per dozen. Lily-of-the-Valley is offered in best quality at \$1.50 per dozen. Gloxinias of glorious color and form are \$1.00 per dozen. These are especially effective for basket work, but as cut flowers also they are very desirable. Mountain Laurel, which is just in flower, is used extensively in large decorations.

GARDEN AND FOREST.

Farmers and Forestry.

MR. A. C. GLIDDEN communicates to the *Rural Home* some sound advice to farmers in regard to their wood-lands, and very forcibly points out some of the harmful falacies in regard to forestry, which now too often find a place in periodical farm literature. A great deal of injury has been inflicted upon the material prosperity of this country by irresponsible utterances of writers and speakers upon subjects relating to forestry, and farmers especially have come to look with suspicion upon any advice in regard to the care of woods and wood-lands. Such articles, therefore, as the one we have referred to, in which the facts are plainly and forcibly stated that the planting of trees upon farms will not increase the rain-fall, and that trees, like other products of the soil, must be cut when they reach maturity, cannot be too often written or too carefully read. We cannot, however, endorse Mr. Glidden's statement that there is less and less demand each year for timber and that other materials are replacing it. Statistics show a wonderful increase in the amount of timber consumed in this country, and while the price of poor, half-grown, brash or knotty timber of all sorts, and of inferior fire-wood, has diminished in some parts of the country, good material of certain varieties of lumber have advanced in price in a remarkable manner. This is true especially of the high grades of white pine, of black walnut, hickory, cherry, white ash, and of other choice hard woods. The prices which these woods now command show that they are becoming scarce, and indicate clearly in what direction farmers can increase the value of their properties by a little systematic attention to trees and their cultivation. This is especially true in the case of farmers living in parts of New England and of the Northern and Middle States, where the soil is of a character which makes the cultivation of trees its only profitable employment. Much has been said about the decadence of New England through the abandonment of its farms, but in all New England there is not an acre of good land really suitable for tillage, which, once cultivated, has been

allowed to run to waste again. What has so seriously injured New England agriculture, and brought agricultural ruin to its people in many towns, is, that land, which was only fit to produce trees, and which, if managed with the wisdom of true economy, never would have been stripped of its forests, has been cleared. This has often been done at great expense, and then at the end of a few years of unprofitable cultivation, such land has had to be abandoned. And what was true in New England a century ago, later, and in a greater degree even, has been true in northern New York; and to-day the same wasteful and short-sighted system is working incalculable mischief in Michigan and in other western States.

The profitable use of lands in the eastern States which cannot be cultivated to advantage is a problem which the farmers sooner or later must solve. Our agricultural population cannot always continue to go west; the best land west of the Mississippi has been occupied, and not an inconsiderable portion of it has already been greatly injured by thoughtless methods of cultivation. As population increases it must depend more and more upon the soil east of the Mississippi for its support; and the prosperity of the country will be great or small as this soil is used wisely or wastefully.

It is a well established principle in countries where the science and the practice of agriculture are much better understood than they are in the United States, that all land suitable for tillage shall be cultivated and that all land which cannot be profitably tilled shall be covered with trees. No tree is allowed to interfere in the arable land with the best development of its field or garden crop; and the poor soil is planted again as soon as a crop of trees has been taken from it. The boundary between farm and forest is rigidly drawn and strictly guarded.

A German farmer would as soon allow his cattle to range in his wheat fields as in his forests, which often prove the most profitable part of a European estate. In this country the wooded part of the farm is not cared for nor protected in a way to maintain and increase its value; it is always used as a pasture in spite of the well known fact that cattle are fatal to a forest; the trees are either all cleared off at once, without reference to their reproduction, or are so carelessly selected for cutting that the character and composition of the woods are ruined. More care is taken now than formerly to prevent and check fires in the woods, but the damage done to forest property in this country by fire is still an alarming item in the national waste account.

No system of agriculture can be long successful and profitable which ignores the necessity of cultivating trees, and which does not recognize the fact that much land in every country can only be made profitable by means of trees. The precepts which should be often repeated to farmers are not that trees produce rain or that trees are sacred objects, which cannot be cut without offense to man and nature. The lessons they must learn, if they hope to compete with the farmers trained under more enlightened systems of agriculture, are that sterile, rocky, hilly ground cannot long be tilled profitably; and that such land can only be wisely used to produce trees; that the pasturage of domestic animals in woods or on land only suitable for the growth of trees, is an expensive and wasteful system, as unsatisfactory from a pastoral point of view, as it is fatal to the forest; that trees are as much out of place in the strong level lands really suitable to permanent tillage as cattle are out of place in the woods. And they must learn, too, that wood-lands can only be made profitable when the same care is given to the selection of trees with reference to soil and climate as is bestowed upon the selection of grain and other crops, and that the rules which Nature has established for the perpetuation of forests must be studied and obeyed.

The belief in the value of forests is increasing in this country; and there has been a marked change in this respect during the last ten years. It can hardly be expected,

however, that the discussion which this interest has evoked will bring practical results to American farmers until they learn the lesson, which experience alone can teach, that much of their want of success in farming can be traced to the use they have made of the natural conditions with which they have found themselves surrounded.

The Artistic Aspect of Trees. II.—Texture.

ONE thing to be considered when a tree is viewed from the artistic standpoint is its form, which, as we have explained, means its size, its contour, and the character of its surface as determined by the number and disposition of its branches and the consequent massing of its foliage. Another thing to be considered is its texture. By this we mean the character of its masses of foliage as determined by the manner of growth of the lighter spray, and the profusion, shape, disposition and tissue of its leaves. We know what differences of texture—of real or apparent solidity and of surface effect—may be produced, for example, by different methods of weaving silken threads—resulting now in silk, now in gauze, now in satin and again in velvet. Analogous differences nature produces in the weaving of the leafy coverings of her trees; and they play almost a greater part in determining the effect of these trees than even varieties of form. If, for example, a Spruce and a White Pine were exactly the same in contour and in the disposition of their foliage into masses, the longer leaves of the Pine and their arrangement in clusters instead of in rows would give it a wholly different effect because a wholly different texture, while the feathery spray and leafage of a Hemlock would appear quite distinct from either. Even between trees of the same genus, as between different species of Pine, very different textures are produced by variations in the length, the rigidity and the number of their leaves. With deciduous trees the case is the same. An infinite variety of texture is found even among species closely allied with one another, and, when leafless, very similar in effect. Leaves may be large or small, numerous or comparatively few, clustered or scattered, held erect or horizontally, or in a drooping manner; they may have simple outlines, or be conspicuously cut or toothed or lobed; may be thick or thin, stiff or pliant in tissue; may be smooth or rough or shining of surface. A variation in any one characteristic greatly alters the general aspect of the foliage, and as there are so many characteristics which may be combined and recombined afresh, it is not strange that Nature's weaving process should result in innumerable varieties of texture.

Upon these varieties depends the expression of a tree, quite as much as upon varieties of form or varieties of color, unless, indeed, color be so peculiar as to be no longer green and form so eccentric as to be hardly normal—as in the case of fastigiate or weeping trees. A tree is sturdy-looking or graceful chiefly by reason of its form; but such varieties in sturdiness as may be expressed by the words severity, sombreness, majesty, picturesqueness, and such varieties in grace as may be expressed by the words fragility, weakness, delicacy, lightness—these spring in very large part from the texture of its foliage. Small leaves, and especially those which are small and elongated or small and quivering, do more than light color to give a tree the aspect of fragility and a feminine kind of grace, while large and simple leaves almost of themselves imply a masculine air, and large, simple and thick-textured leaves mean a certain majesty even in a plant so small that it is considered a shrub. A small Magnolia, for example, has more dignity than the largest Honey Locust. A Catalpa is more masculine-looking than a Willow of even the largest size; and if we imagine the thin tissue of its leaves exchanged for a thicker, stiffer tissue, we can easily see how its dignity would be still further increased. Even the difference in substance between the foliage of the American and the European Beech—the latter being some-

what stiffer and much glossier—makes a difference in the expression of the two trees; and there is a great contrast in expression, despite much similarity in form and structure, between the White Oak, with its large, round-lobed, dull-surfaced leaves, the Scarlet Oak, with its deeply cut and glossy leaves, and the Willow Oak, with its very small and simply outlined and still glossier leaves. A uniform texture—caused by comparatively small leaves, regularly and thickly distributed over the branches—gives a tree a quiet, restful look, while a broken, spotted texture, caused by sparse, scattered and conspicuously cut leaves (as in the Sycamore), gives it an unquiet look.

All such facts, the "commonplaces of the landscape gardener," should be noted and appraised by every one who aspires to merit the title of a lover of trees. There are none richer in possibilities of pleasure to the cultivated eye even if actual work in the way of planting is not in question—for while forms vary much in trees and colors vary much, textures vary more; among smaller woody plants individuality chiefly depends upon them; and while their variations may seem less striking than those of form and color to the careless observer, they soon grow to be equally conspicuous with the growth of the observing and the appreciating faculties.

When planting is in question, however, they are of great importance. It is almost as bad to group trees inharmoniously with regard to their textures as with regard to their forms. Any artist would know that trees which are quiet and restful in effect may be used in larger masses, and will less conspicuously affect the appearance of their neighbors than those which are spotted and restless of aspect. He would know, too, that it is better to relieve a light and feathery tree against a group of more solid foliage than to reverse the terms of the combination. He would know that the massive, uniform surfaces which make a good background are less pleasing in an isolated specimen standing near the eye. He would know that the great, glossy, leathery leaves of the Evergreen Magnolia are just what is wanted in one spot, just what is not wanted in another, and that while the trembling leaves of the Aspen, or the drooping, fringe-like texture of the Cut-leaved Birch, unfit it for many positions, they make it especially valuable for others. He would know that with every change of position and environment comes a change in the effect of the texture of a tree—that while one sort will look well in full sunlight, another will look better in a shadowed spot, another overhanging a stream, another set close against the walls of a house. An artist feels all this in advance if his profession be landscape gardening; and he feels it at least in intelligent appreciation of existing results if it be some other branch of art, for it is every artist's habit to appraise all he sees for the three properties of form and texture and color. But how few amateur planters feel it in advance; how few lovers of trees judge their own or their neighbors' places with such tests in mind! Even when questions of form and of color are somewhat regarded, questions of texture very seldom are. Yet a cultivated eye is as much distressed by seeing a rigid-looking Pine or a solid Sugar Maple where a feathery Hemlock or a delicate Honey Locust might better stand, as by seeing a Purple Beech where harmony calls for a green one, or a lofty Hickory where good composition demands a low and spreading Dogwood.

The trees in the Central Park, in this city, have not looked as well as they do just now for a number of years. The cool, late spring, the abundant rains of May and the heat of the early summer have all been favorable to a vigorous and healthy tree-growth. Most of the trees, with the exception of the half-dead Norway Spruces, which are covered with red spiders, are unusually free of insect pests. The American Elms have made a remarkable growth, and when planted under favorable conditions, are now objects of great beauty. The American and European Lindens are

very fine, too, and several species are now covered with their fragrant flowers. The two Silver Lindens (*Tilia argentea* and *T. petiolaris*) are striking and attractive in habit and in the pleasing color of their foliage. No foreign trees are better entitled to a place in our plantations than these two European Lindens, of which many fine specimens exist in the Park. The six thousand trees which have been removed from the Park during the past year are not missed. The work, as far as it goes, seems to have been judiciously planned and executed. No one would now suspect that a single tree had been cut; and the Park plantations and the general appearance of the Park would be immensely improved if thirty or forty thousand trees were removed during the present year. They would no more be missed than those already cut are missed. Dying Conifers still disfigure the Park in all directions; everywhere fine trees are in danger of being ruined from overcrowding, while the removal here and there from the plantations of inharmonious elements, as where, for example, trees with light and feathery habit are too closely associated with round-headed, compact trees, would add immensely to their natural and harmonious appearance. There are cases, too, where trees of peculiar rarity or interest should be freed from encroaching neighbors, that their full development and long life may be insured. This is the case with the Asiatic Elm (*Ulmus parviflora*), which stands near the Seventy-second street entrance from Fifth Avenue. This is without doubt the largest and finest specimen of this rare tree in the United States. It is a specimen not only of extraordinary interest, but of great and peculiar beauty. It now forms one of an inharmonious group of three trees. On one side it is being pushed out of shape by a common Tupelo or Sour Gum tree, while its branches on the other side are stunted by a common European Maple. It is hard to imagine a more incongruous or less pleasing combination of trees; and it is clearly for the interest of the Park and of the public that the Maple and the Tupelo should be cut away and that every opportunity should be given to the Elm to spread its branches out freely in all directions. There are hundreds of just such cases all over the Park where interesting and valuable trees are being ruined in this way; but in the particular case to which we venture to call the attention of the Park authorities, the prominent position of this beautiful tree and the great interest which it excites among all persons who know it, seem to warrant us in urging prompt action to insure it from further disfigurement.

Palms in Central Florida.

PROBABLY in all the United States there is not such a collection of Palms growing in the open ground as that of Mr. E. H. Hart at Federal Point, Putnam Co., in this State. Dr. Richardson, of New Orleans, has a good collection of hardy Palms growing in the open ground, but the extremes of cold experienced there are much greater than those of Mr. Hart's location, and only the most hardy species can be safely planted out.

The approach to Mr. Hart's residence is through the Orange grove, famous throughout the South for the number and excellence of the varieties of fruit grown, and containing between the Orange trees hundreds of the choicest exotic fruit trees, flowering and ornamental shrubs and Palms in the greatest variety. It is of the Palms more especially that I now wish to speak.

Overlooking masses of *Magnolia fuscata*, *Rhinospermum jasminoides*, *Olea fragrans*, *Azaleas*, *Tabernamontana*, *Allamanda*, and other beautiful plants, one's attention is first attracted by a group of different species of the genus *Phoenix* in front of the house. The tallest of these is a magnificent specimen of *P. sylvestris*, the wild Date of India, with a trunk some twelve feet in height and a total height of twenty feet. (It must be remembered that none of Mr. Hart's Palms have been planted out more than fifteen years, and most of them during the last ten years, so that in many species stem development has not even begun.) This beautiful tree had bloomed, and a spike of fruit was developing at the time of the extreme cold of 1886; this, of course, was destroyed, and no flowers have appeared since. Close by is a *Phoenix Canariensis*, with a short

trunk, and still more elegant leaves than those of *P. sylvestris*; the leaflets are set closer together, making a very compact and beautiful leaf. Another specimen, though smaller, is *Phoenix vivifera*, a more tender species, which suffered badly during the winter of 1886, but is still a very handsome and thrifty plant. Among the Orange trees are two elegant plants of *Phoenix rupicola*, a most graceful species. The handsome recurved leaves are a rich golden-green color rarely seen in any Palm. These plants are about five feet in height, this species never forming a tall trunk. There are other fine specimens of the different species of *Phoenix* in different parts of the grounds, especially in what was once the garden, but is now a thicket of Palms. We noted also *Phoenix tenuis*, *P. pumila*, *P. farinifera*, *P. Senegalensis*, *P. spinosa*, *P. reclinata*, *P. dactylifera* (the common Date Palm) and others. In striking comparison with the vigorous, healthy and remarkable growth of the various species of *Phoenix*, we remember a tiny plant of *Copernicia macroglossa*, ten years old, and with one little leaf, not more than an inch high.

Directly in front of the house is a clump of the slender little Cane Palm (*Rhapis flabelliformis*). The stems of this miniature Palm are about three-fourths of an inch in diameter and two or three feet high. It suckers freely like a Bamboo, and the clump now contains fifty or more distinct stems. This plant was little injured by the cold of 1886, and is ordinarily quite hardy.

The neat, trim little specimens of *Chamærops* throughout the grounds are very beautiful. Among these are *C. spinosa*, *C. Humboldtii*, *C. arborea*, *C. elegans*, *C. tomentosa*, *C. Martiana*, *C. Fortunei*, *C. humilis*, *C. Sinensis*, *C. farinosa*, *C. humilis robusta*, *C. robusta*, *C. excelsa*, *C. excelsa macrocarpa*, our native *C. hystrix* (or *Rhaphidophyllum*) and others. One of the largest of these is *C. robusta*, which has reached a height of six feet, with a trunk three feet high. Many of them have beautiful little silvery leaves and small slender trunks from three to five inches in diameter. All are perfectly hardy in this latitude, so far as cold weather is concerned, but *C. humilis* and one or two others do not, while small, support our summer sun very well. *C. excelsa* has rich green leaves, without the silvery tint so often seen in the other species.

Among other Fan-leaved Palms is a splendid collection of *Sabals*. These are usually hardy; even the species whose native home is in the tropics. One magnificent specimen of *S. umbraculifera* has attained a height of about fifteen feet, with over six feet of trunk. It has a beautiful spreading crown of leaves resembling those of our native *S. Palmetto*, though with longer and stouter petioles, and thicker, firmer texture. A specimen of *S. dealbata* is about six feet in height. This has produced seed on a spike ten feet high. There is a fruiting specimen of *S. longipedunculata*, with the flower-spikes extending far above the leaves after the manner of *Sabal Adansonii*. A fine specimen of *Sabal Mocini*, from the highlands of Mexico, has proved somewhat more tender than the native Cabbage Palmetto, the foliage having suffered in 1886. There are in this collection also *Sabal Havancensis*, *S. Ghiesbreghtii* and *S. caruleus*, all in good specimen plants.

Mr. Hart has made a great success with *Washingtonia robusta*, one of the California Fan-Palms, of which he has several fine trees. The largest is fifteen feet in height, with about six feet of trunk; it throws out a new leaf every two weeks, and is indeed a beautiful specimen; the red wax-like spines and richly-tinted leaves and petioles make it one of the handsomest and most desirable Fan-Palms I have ever seen. *Washingtonia filifera* (*Brahea* or *Pritchardia filamentosa*), the southern Californian Palm, is very distinct. Although Mr. Hart has beautiful specimens, they are deficient in vigor as compared with those of *W. robusta*. *Brahea edulis* and *Brahea glauca* are represented in smaller specimens.

Perhaps the most elegant Palm in the whole collection is a ten-year-old *Diplothemium campestre*. It is not more than four or five feet in height, but the beautiful plume-like leaves, silvery on the under side, and the leaflets delicately curled like those of an ostrich feather, make up in beauty for want of size.

The genus *Cocos* is well represented in the more hardy species; a specimen of the quick-growing and handsome *C. flexuosa* is twelve feet high; the most hardy species, perhaps, of all pinnate-leaved Palms, *C. australis* and *C. campestris*, are represented by many thrifty young specimens. *C. Yatai*, *C. insignis*, *C. Romanzoffiana*, *C. Normanbyana*, *C. Gaertneri* and *C. Blumenavia* are represented in small specimens; *C. plumosa*, a species with long, drooping, light-green leaves, appears in a good-sized specimen.

I noticed a small plant of *Livistona altissima*, another of *L. Jenkingsiana*, and a splendid specimen of *L. Hoogendorpii* four or five feet high. In front of the house is a magnificent

specimen of *L. Chinensis*, about eight feet high, that has formed a considerable trunk already. Near by is an *Acrocomia selerocarpa* about four feet high, raised from a seed planted eight years ago, and which did not germinate for four or five years.

A *Fubaa spectabilis*, twelve years old and not over a foot high, though apparently healthy, seems to warrant the assertion that in Chili, its native country, this Palm is one hundred years old before it produces flowers and seed.

Areca rubra, *A. sapida* and other species of this genus are grown with the protection of a shelter made of slats placed several inches apart, in order to afford partial shade and protection from frost.

A good specimen of *Oreodoxa regia*, the "Royal Palm" of southern Florida and the West Indies, has been protected through several severe cold snaps by headless and bottomless barrels slipped down over the leaves and around the trunk, and then filled up with earth.

Many other Palms are represented in small specimens, but I have noticed most of those that have attained any size.

Cycads, too, are well represented. First and foremost there is a noble specimen of *Cycas revoluta*, about fifteen years old, and in the healthiest possible condition. Scattered in various places throughout the grove and grounds are at least as many as a hundred more small specimens of the plant. *Zamia integrifolia*, our Florida species, is there, as well as the rarest exotic species, like *Macrozamia cylindrica*, *M. Dennisonii*, *Dioon edule*, *Cycas circinalis*, *Macrozamia terrestris*, etc.

In a few years the "Palms of Federal Point" will be well worth a long journey to see.

Manatee, Fla.

P. W. Reasoner.

Foreign Correspondence.

London Letter.

IN my last letter I spoke about the many beautiful American trees and shrubs that were now making our open-air gardens so gay with bloom. I ought to have finished the list by recounting the charms of the numerous Oriental plants which enrich English gardens. Chinese and Japanese trees, though not so hardy and so suitable for our climate as American, are, nevertheless, invaluable, and if some of them are killed in a severe winter, the choice is so great that we can afford to leave aside the tender things in making a selection. Just past is the glorious Yulan (*Magnolia conspicua*), which has been the attraction of many a garden, and this year, owing to the lateness of the season, it has been more beautiful than ever, having escaped the late frosts and cold winds. Of the several forms of it there is none to equal in purity the snow-white form, whose flowers have not the faintest trace of color. A large mass of this was exhibited at the Royal Horticultural Society a short time ago, and though surrounded by the rarest and showiest Orchids and other plants, every one who saw them was captivated by their chaste beauty. Quite recently I saw at Mr. Anthony Waterer's nursery at Woking a large bush of another white eastern Magnolia (*M. stellata* or *M. Halleana*, as it is also called). It was standing out in the open entirely without shelter, and every bloom was as pure as if grown under glass. These two Magnolias are among the loveliest trees one can possibly have in a garden. The *Exochorda grandiflora*, otherwise called *Spiræa grandiflora*, from north China, is a shrub that is rapidly becoming popular with us since it has proved to be quite hardy. At one time it was always planted against a wall, but now one sees great bushes of it eight or ten feet high and as much through. The snow-white flowers, an inch or more across hang thickly wreathed on every branch, and, in contrast to the tender green foliage, are delightful. The Japanese Apples have been exceptionally fine this season. I do not know if they are much planted in America, but here there is such a growing demand for them that nurserymen cannot keep pace with the supply. The best of all is undoubtedly *Pyrus* (*Malus floribunda*), and one of the finest of all flowering trees. The profusion of its flowers and buds renders it most striking at this season, especially before the deep crimson buds expand into shades of deli-

cate pinks. I plant this beautiful tree wherever I can, knowing well how hardy it is, and how rapidly it makes a picturesque, though small, tree. In old gardens like Kew, the Chinese *P. spectabilis*, a very old introduction, has been very attractive in bloom, but it is not nearly so valuable for ornamental planting as *P. floribunda*, neither are the varieties *Toringo*, *Kaido*, *Riversi* and *flore pleno*, which I put in the same category as the Siberian *P. baccata*, which has the additional value of its cheerful crop of autumn fruit. *Pyrus Maulei* is one of my chief favorites among dwarf shrubs. Its flower color, a sort of orange red, is incomparable, and just now, when this peculiar tint is in harmony with the pale leaf green, the shrub is charming. It is admirable for planting on the margin of a group of our old friend, *Cydonia japonica*, on a lawn. By the way, there are some splendid forms of the *Cydonia* now, but after seeing a full bloom review of them at the Knap Hill nursery, I think that there is none to compare in richness or brilliancy of color with the sort called *cardinalis*, whose flowers are big, of fine shape and of a glowing crimson. Then for purity, the variety *nivalis* is unmatched, being far better than the so-called white (*alba*), which has traces of color. All the other sorts, so far as I can see, range between *cardinalis* and *nivalis*, and the only one I should select besides them would be *rosea*.

The Japanese Snow-ball bush (*Viburnum plicatum*) deserves all the praise you see written of it, for it is unsurpassable in its way. I saw it the other day in the Coombe Wood nurseries flowering profusely in an exposed border, every bush being a mass of white. The "balls" of flowers are larger than those of the common *V. Opulus sterilis*, and whiter, while the plant is dwarfer, and particularly suitable for a select shrubbery. I have recently seen the double *Wistaria sinensis*, and do not think much of it compared with the glorious single kind, which for the last few weeks has met me at every turn on mansion, cottage and bower, clad with a profusion of mauve bloom. The double kind is not so showy, because the flowers seem doubtful about opening themselves widely, and though when fully expanded they may last longer, in good condition, than the single, I do not think that that point compensates for the lack of profuse bloom, brightness and elegant growth. When I was in Belgium recently I heard some nurserymen discussing the merits of a new variety of *Wistaria* which is "coming out." It is said to be wonderful, far eclipsing the long-spiked *W. multijuga* and other sorts, its racemes being a yard long. I shall watch its advent with interest.

London, June 8th.

W. Goldring.

New or Little Known Plants.

Philadelphus Coulteri.

PROBABLY no flowering shrub is more popular with common folk, after the Lilac, than the "Seringa," especially the European form (*Philadelphus coronarius*), with creamy, fragrant flowers. Our own species, with larger, pure white flowers, but much less fragrant (*P. grandiflorus* and *P. inodorus*, with their varieties), are also favorites, and very common in yards and shrubberies. Others are scarcely known. The Californian *P. Gordonianus* is sometimes to be found in gardens, and it has large flowers and is very handsome in cultivation. The very similar *P. Lewisii*, which ranges from Oregon to north-western Montana, is a free bloomer, and probably its equal in every way. The two species of western Texas and New Mexico, *P. microphyllus* and *P. serpyllifolius*, are dwarf in habit and have much smaller leaves and flowers.

The species of which a figure is here given, is from northern Mexico, where it was discovered by Coulter many years ago, and again by Professor Sargent in 1887 on the foot-hills of the mountains near Monterey. It equals our common species in height, with slender, drooping branches, and leaves which have a dense, white pubescence cover-

ing the under surface. The flowers are mostly solitary along the branches, an inch broad or more, and very fragrant.

The relationship of the genus *Philadelphus* is interesting enough to be worth mention. With *Hydrangea* and *Deutzia* it belongs to a saxifragaceous tribe (*Hydrangeæ*) which is limited to the northern temperate zone and mainly to eastern Asia and eastern North America. *Philadelphus* is exceptional in having one species in Europe and two upon the Pacific coast, in addition to the eight more eastern species and the two of eastern Asia. *Hydrangea*, on the other hand, has but three species in eastern America and thirty or more Asiatic, while *Deutzia* is wholly Asiatic. The remaining genera are all very small, of a single species, or rarely two in each. Of these we have *Decumaria* in the Atlantic States, *Fendlera* and *Jamesia* in the Rocky Mountains, *Whipplea* in Utah and California, and *Carpenteria*, also Californian. One genus is found in the Sandwich Islands, and the five others all belong to eastern Asia. It is a curious fact that the *Itea Virginica* is our sole representative, and almost the only representative on this Continent, of another similar and as large a tribe whose home is in the southern hemisphere, scattered likewise

two feet more and the color is brilliant golden yellow. We are accustomed to see *Papaer orientale* in several shades of scarlet and blood red, but there is now a sport in rosy lilac. *Lathyrus Sibthorpi* is not a new plant, but it is seldom seen and it deserves a place in a choice collection. Its flowers are of a uniform, bright magenta-red and appear in great numbers. *Gundelia Tournefortii* is a rare Persian plant, not showy, but a great beauty; the thistle-like leaves are deeply cut out, rather spiny, of a bright green color with conspicuous white nerves; the flowers are chocolate and yellow, a very curious combination, but most striking. *Lindelofia longifolia* is a showy herb, sending up a dozen stems to a height of two feet, each clothed by numerous lance-shaped leaves and terminated by a cluster of ultramarine blue, Forget-me-not-shaped flowers. *Pulmonaria Daurica* is a dwarf alpine; a tuft of lance-shaped leaves mounted by panicles of pretty bright blue pendent flowers. *Polygonum sphaeroslachyum*, a showy plant from Sikkim, continuously puts forth from amidst bright green, longish-lanceolate leaves, its charming rosy crimson flowers. *Armeria undulata* has pure white heads borne on long undulate stems. *Gladiolus vinulus*, grown in a frame, is a very pretty small-flowered species which will be much

Fig. 40.—*Philadelphus Coulteri*.—See page 232.

mostly in small genera through western South America, the islands of the South Pacific and Indian Oceans, Australia and South Africa. But *Itea* is the only genus of this tribe that is represented in eastern Asia also, and our own species finds its nearest relative in one peculiar species of Japan.

Plant Notes.

Novelties at Baden-Baden.

A PART of the terrace-like rough walls in my garden is clothed in blue, violet and crimson-lake by the various varieties of *Aubrietia*, the crimson-lake-colored *A. Leichtlinii* being very conspicuous. *Iris albicans*, a native of Cyprus, is in the way of *I. Germanica*, but pure white, very rich, and deliciously sweet scented. *Delphinium Brunonis* is a dwarf, very large flowered Himalayan species; the flowers are grayish blue, very downy, and strongly musk-scented. *Eremurus aurantiacus* is one of the showiest species. The scapes are some three feet in height, the spikes of the thickly set flowers take one and a half to

valued for bouquets. It is creamy white with crimson feathers.

Max Leichtlin.

Schizophragma hydrangeoides.—This interesting Japanese climbing plant is now flowering finely in the garden of Mr. S. B. Parsons, at Flushing, Long Island. It must not be confounded with the "Climbing *Hydrangea*" sometimes seen in American gardens, which, although distributed under the name of *Schizophragma* a few years ago, is an entirely different plant (*Hydrangea radicans*), with dark green, finely serrate leaves, and broad, flat-topped inflorescence, the outer or radiating flowers, as in other *Hydrangeas*, with three or four enlarged, petaloid sepals. *Schizophragma* has much paler and more deeply heart-shaped leaves, with reddish veins and petioles, and a much deeper and more prominent serration. The flowers are arranged in a loose spreading, many-branched corymb six or eight inches across, each branch terminated by a pure white petaloid, oval leaf, nearly an inch long, corresponding to the petaloid calyx lobes of the ray-flowers in *Hydrangea*, but with only a single division developed, and with no other trace of the flower remaining. The small, perfect flowers are greenish yellow, and, although produced in great profusion, are not showy, the beauty of the plant consisting in its very handsome foliage, and conspicuous petaloid calyx lobes.

Schizophragma is found in the elevated valleys of the mountains of Japan, where it climbs over rocks and the trunks of trees to a height of eight or ten feet. The Japanese name, *Tsuru demari*, signifies the Climbing Snowball, a name which describes the general appearance of the plant. It is well figured by Siebold and Zuccarini in the "*Flora of Japan*," t. 26, while a figure, *Hydrangea radicans*, will be found in the *Botanical Magazine*, t. 6788 (under *H. petiolaris*). These two climbers are important additions to the small number of plants hardy here, capable, like the English Ivy, of attaching themselves firmly to the trunks of trees by adventitious roots developed on the stem and branches. S.

Benthamia Japonica is probably flowering for the first time in the United States in the Parsons nursery, at Flushing, Long Island. It may be described as a dwarf Flowering Dogwood, in which the flowers are not produced until after the leaves have attained their full size. It is a compact shrub, six or eight feet high, with bright green, elliptical leaves and compact heads of small yellow flowers, surrounded by four pure white, satiny, petaloid bracts as long, but much narrower, and more sharply pointed than those of the Flowering Dogwood. This is a very interesting and important addition to the list of showy-flowering shrubs, hardy in the Northern States, where it seems destined to become a conspicuous garden ornament. It is one of Mr. Hogg's introductions. S.

The Cherokee Rose.

IN extra-tropical regions with temperate climates it is the injurious weeds of foreign countries and not the useful or ornamental plants which, as a rule, become naturalized. A hundred old-world weeds, at least, injurious to our crops, are now as much established, and in some instances more widely distributed, in the United States, than in their own homes, while of plants useful to man there are not probably half a dozen foreign plants naturalized in this country. The most conspicuous examples of useful plants now thoroughly established in the United States are the Barberry on the New England coast, the so-called Japanese Clover in the south, the Oat in California, the Wild Orange in Florida, and the subject of our illustration on page 235, the Cherokee Rose (*Rosa laevigata*), now thoroughly naturalized and widely distributed through a large part of the south Atlantic and Gulf States. It is a common plant in many districts of southern China and Japan, but it is not recorded how the Cherokee Rose first reached America, in whose garden it was first planted, or how it escaped to the woods and took such a hold upon the soil that it acquired the name of the tribe of Indians which once occupied much of the upper country in what are now the States of Georgia and the Carolinas. Michaux, the French botanist, found it in Georgia late in the last century so thoroughly naturalized that he mistook it for a native plant and first published it in his North American Flora many years before it was known as a Chinese plant at all. Elliott speaks of it in his "*Sketch of the Botany of South Carolina and Georgia*," published in 1821, as having been "cultivated in the gardens in Georgia for upwards of 40 years, under the name of the Cherokee Rose." It is a shrub with long flexible branches which may be trained to a height of 15 or 20 feet, but which if left unsupported fall to the ground and take root. This habit, its vigorous, rampant growth, and the stout, sharp, incurved prickles with which its branches are armed, admirably adapt the Cherokee Rose to form high hedges, which, if left unpruned, soon form thickets twenty or thirty feet through, into which no animal will penetrate. There are hundreds of miles of such hedges lining the highways in different parts of the Southern States, and nowhere are they more beautiful and luxuriant than in that part of western Louisiana watered by the Achafalaya and the Têche. When in bloom the Cherokee Rose is an object of much beauty, its pure white, single, fragrant flowers, two or three inches across when expanded, contrasting charmingly with the dark, shining, ever-green foliage. There are few floral displays in this country more delightful than a long vista bordered with great masses of this graceful plant in full flower. The

Cherokee Rose is an excellent subject to train over the roof of a cool green-house at the north, where, if it can be planted out in a border, it soon attains a large size and produces every year during the month of February an abundant crop of flowers. Our illustration is from a photograph taken recently in Florida, by Dr. R. H. Lamborn; it shows a hedge of this plant from which the long pendulous branches have been removed in order to keep it within reasonable bounds.

Cultural Department.

Canterbury Bells.

OF these grand, old-fashioned flowers we now (middle of June) have a very fine display—some 150 plants in full bloom in one belt. Although single plants are very beautiful, their excellent effect is attained only when a large number of them are grown and massed together, like Pæonies, Poppies and Coreopsis. They come into bloom when herbaceous Pæonies and Oriental Poppies have passed their best, and before the gorgeous Kœmpfer's Irises begin to flower, and they are in perfection at the same time as June Roses, Deutzias and the large flowered Philadelphus.

Canterbury Bells are true biennials and of the easiest possible cultivation. We have never succeeded in flowering them the first year from seed, and although they will sometimes live over for another year after blooming, in the same way as Foxgloves and Hollyhocks, they never are satisfactory when so retained; far better treat them strictly as biennials. But they are not quite hardy, and this alone is the reason why they are so seldom seen or grown in our gardens. We sow the seed in flats (shallow seed boxes) in a cold-frame in June or July, and soon after the seedlings appear they are pricked off into other flats, and after a few weeks planted out six or eight inches apart each way into frames or a narrow bed in the open garden. Sowing in flats is a matter of convenience rather than necessity, as the seeds are very small, and if sown in the open garden warm sunshine would be likely to burn them, or heavy rains wash them out or cover them too deep. The cold-frame is also only a convenience in the same way, and by shading the sashes and ventilating at the same time, we have in it an excellent place for starting seeds in summer. It is not well to sow the seeds in spring; if sown early the plants grow into large masses before summer is over and are very apt to rot off in winter. Many years of practical observation convince us that midsummer is soon enough to sow Canterbury Bells.

Before hard frost sets in lift the plants and transplant them into cold-frames, in the same way as is done with Pansies, Violets or Lettuces, and, according to the size of the plants, some six to eight inches apart. If the plants are vigorous and leafy, shorten back the leaves a good deal so as to keep the plants from touching each other; when too close they gather and hold moisture on the surface of the leaves; and then the crowns rot off in winter. But avoid coddling or keeping them warm; just cover the glass with a few inches of straw and ventilate in bright or warm weather. But keep a strict watch on the frames for field mice. These little and extremely destructive rodents gather to the frames in winter and cut the plants all to pieces. A few Peas or grains of cereals, dusted over slightly with Paris green and buried half an inch deep in the ground, is a very good bait for the mice.

Towards spring expose the plants quite freely in order to render them hardy and retard their leaf growth, and as soon as the ground out-of-doors is free from frost and mellow lift and transplant them to the garden where it is desired to have them bloom. In lifting cut the ground between the plants lengthwise and crosswise, and in this way you can lift them with large unbroken balls.

There are many kinds of Canterbury Bells (*Campanula Medium*), single and double; also the cup-and-saucer forms known as calycanthea; and in color they range from pure white to rose and blue, but the shades of purple, violet and blue prevail. And while all are beautiful, the double ones are most esteemed, and of the doubles the *calycanthea* varieties are preferred. The finest variety we have ever grown is *calycanthea rosea*, and the next most beautiful is *C. Mauve Beauty*. But it is desirable to have a variety of colors, and from a packet of mixed seed of each of the above sections—namely, single, double and calycanthea—there will be a great variety of colors, but there should be a special packet of *calycanthea rosea* seed.

Canterbury Bells are not only most excellent plants for garden use, but as cut flowers for house decoration, where, as in the case of halls, large masses are required, we have nothing better, and they last well when cut. *W. F.*
Glen Cove, N. Y.

Myosotis dissitiflora.—Although this beautiful perennial Forget-me-Not does not come in early enough for spring bedding, owing to the loss of the previous year's flowering growth during winter, yet it does excellent service in brightening up the garden during the interval between spring and summer bedding. For the front line of herbaceous borders, and round and about shrubberies, as an edging, it is charming. It will bloom all through the summer, but later its brightness becomes somewhat obscured by the blaze of summer bedding plants. It differs from *M. alpestris*, which is really an annual—having the inflorescence proceed directly from the root-stock—by flowering, and rooting all along its decumbent stems, any of which quickly form a plant when separated.

species we are not all successful, though it is very plentiful in the woods about 200 yards away. The large and handsome *C. spectabile* will soon be in flower. This kind delights in deep beds of swamp peat and moss, in light situations. This, as well as the yellow kind, make excellent plants for pot culture, can be forced readily, and will remain in good condition for many years with simply an annual top-dressing of moss and peat. *F. G.*

Orchid Notes.

Thunia alba.—As more than half a century has elapsed since this Orchid was introduced, and as it is easily propagated, it is surprising that more of it is not grown. We have a large batch in flower now, and we find it exceedingly useful for cut flowers and for decoration, both for the conservatory and for the dwelling house. They can be had in flower within two months from starting, and to make a good plant for general decoration, eight or ten bulbs should be put into an eight-

The Cherokee Rose—See page 234.

Rockets.—The old double white and purple varieties are now in bloom. They are among the handsomest of hardy plants, and should be generally grown. The flowering stems resemble, and equal in beauty, those of a well-formed Brompton Stock, and remain in bloom much longer. They require only a good loam—if heavy so much the better—and a little shade. They are propagated by cutting back any flowering stems which may start towards the fall, in order to encourage the development of offsets, which should be removed and kept over winter in a cold-frame for safety.

Wellesley, June 16th.

T. D. Hatfield.

Hardy Lady Slippers.—One of the principal features of the out-door garden just now is several large patches of the yellow species of this interesting family. Some of these clumps are bearing seventy to eighty flowers. *Cypripedium pubescens*, the larger variety, does best with us planted in a friable loam in partly shaded ravines. On the other hand, *C. parviflorum*, the smaller variety, likes a good deal of peat, being a bog-loving kind, but disliking too much shade. One fine patch planted by the side of a gravel path has outgrown its bounds, and where it has encroached on the walk the flowers are smaller and lose the dark brown of the petals. A few plants of *C. acaule* are in flower, planted among Kalmias, but with this

inch pot. The bulbs or stems usually grow from two to four feet in height, and terminate in a drooping raceme of pure white flowers, beautifully penciled with purple and lilac. These will last in perfection from two to three weeks. To grow this species well it should be accorded very liberal treatment, potting in well drained pots in a mixture of equal parts loam, peat and moss with a good sprinkling of sand. Little water should be given until the growths are a few inches high, after which they may be kept very wet; a good top dressing of moss and cow manure will be beneficial, as well as liquid manure applied three times a week. The warmest house should be given them, and the plants should be constantly syringed overhead. As soon as growths are finished, the plants should be ripened in a cool, airy house, giving abundance of water until all the leaves are dropped; after this scarcely any water need be given except to keep the stems from shriveling. All the roots die every winter, consequently they will need to be shaken clean out, the old roots cut off and potted in fresh soil every spring, as soon as new growths appear. To propagate this species the stems, in the spring, should be cut in lengths of four to five inches and inserted in pots of equal parts sand and leaf mould, and put in a close frame until the buds are well advanced, when they may be treated the same as the older plants. There are three to four other species belonging to the genus,

but differing from this one only in the markings and color of flower, and requiring the same treatment. They are natives of Burmah.

Phalænopsis Parishii.—An exceedingly choice little Orchid with thick, fleshy roots and distichous tufts of pale green leathery leaves about four inches long. The racemes, which are large for the size of the plant, bear eight to ten flowers, less than an inch across, sepals and petals pure white, lip three-lobed, the lateral ones small, yellow, with purple blotches, the front one broad, flat, and of deep amethyst purple. It is an exceedingly free blooming kind; the smallest piece will produce at least two racemes, and the charming contrast of color, in the dense mass of flowers, renders it very attractive. It is a native of Burmah, and grows best on block or raft of wood. It should at no season be allowed to be dry, and delights in abundance of heat and moisture in the growing season.

Miltonia Phalænopsis.—This is the smallest of the half dozen species popularly known as Odontoglossums, but now referred to Miltonia. It has oblong, compressed bulbs, bearing narrow, grass-like leaves about a foot long. Strong bulbs will produce three to four spikes, each bearing three to four flowers, pure white, the broad pandurate lip having two large broken blotches of purplish crimson. This species is a native of Guatemala, and is thriving with us under the treatment recommended for *M. vexillarium*.

Phalænopsis speciosa Imperatrice is a distinct variety of a very showy species, producing panicles of bright rosy purple flowers, excepting a white tuft of hairs on the apex of the lip. The back of the flowers is faintly striped with rose. Another choice and rare variety is Christyana, in which the purplish flowers are banded with pure white. These, with the type, are native of the Andaman Isles, and therefore need the warmest house, and should at no time be allowed to become dry. Sphagnum moss, with a few lumps of fibrous peat, is the best potting material.

Denrobbium Dearei is one of the best of recent additions to this large genus. The racemes, usually eight to ten flowered, proceed from opposite the axils of the leaves or from the old leafless bulbs, in profusion, bearing comparatively large, pure white flowers, relieved with just a dash of pale green on base of lip. These will remain in perfection fully four months, and apparently without injury to the plant. The old bulbs, though adding nothing to the beauty of the plant, should be allowed to remain on, as they will continue to give racemes for many years. The cultural requirements of this species has not been generally mastered, as good examples are the exception. It does well in the warmest house the whole year, being saturated with water during growth, and at no time being very dry. It requires little potting material.

Kenwood, N. Y.

F. Goldring.

Notes from the Arnold Arboretum.

Ledum latifolium, the Labrador Tea, is now covered with its handsome heads of white flowers. It is a dwarf evergreen shrub, which grows in cultivation to a height of one or two feet, with erect, very leafy stems, and oblong, linear leaves with revolute margins and covered on the under side with ferruginous wool. An inhabitant of cold swamps, it is a peat-loving plant, and a good subject for the margins of Rhododendron beds. Although a plant from the far north, being found from Labrador to Puget Sound, like most broad-leaved evergreens, it is the better in this climate for a slight winter covering.

The Sand Myrtle (*Leiophyllum buxifolium*) is also in flower. It is a handsome dwarf evergreen shrub, only a few inches high, very common in sandy Pine-barrens from New Jersey to Florida. It has minute, oblong, veinless leaves, and profuse white or rose-colored flowers in terminal umbel-like corymbs, made conspicuous by the brown or purple anthers. The variety (var. *prostratum*) which is found only on the summits of the Roan and other high Carolina mountains, where it forms dense wide carpets, flowers here nearly two weeks earlier. It is hardly more than an inch high and has deeper green leaves than the New Jersey plant.

Among all the Mountain Ashes, American, European and Japanese, none is so handsome as *Pyrus sambucifolia*, the most northern of the American species and only just reaching the eastern United States on the highest of the New England mountains and the shores of Lake Superior. The oblong-oval divisions of the leaves are much broader than in the other species; the petioles and peduncles are a brighter red and the fruit is much larger and higher colored. It makes a fine tree in cultivation, especially far north; and in the gardens of

Minnesota and Wisconsin, where it is often seen and where it soon grows into fine large specimens, it is, in autumn, an object of surprising beauty. It is rarely met with at the east, however, although well suited to the climate of New England and New York; and its more general cultivation is worth the attention of nurserymen. It is in every way the superior of the European Mountain Ash, which is the species found in American nurseries.

Daphne alpina, a native of the European Alps, is very handsome when covered with its pure white, abundant, fragrant, sessile flowers. It is a dwarf shrub, not more than a foot high here, with deciduous leaves. It requires a slight winter protection to insure an abundant crop of flowers, as the plant is not entirely hardy here.

Fendlera rupicola is an interesting plant of the Saxifrage family, related to *Deutzia*, and a native of our Texano-New Mexican region, being found growing sparingly in the rocky crevices of river bluffs from the Guadalupe to New Mexico. It is a low shrub, two to four feet high, with small, opposite, entire, sub-sessile leaves, and large white, showy flowers with long, conspicuous stamens, solitary on the extremities of stout lateral branches. *Fendlera* is perfectly hardy here, and a real acquisition to the list of dwarf garden shrubs which can be grown in this climate.

Among Barberries with racemose flowers of the *vulgaris* section are several species or varieties in the collection worth more general cultivation. *Berberis Canadensis* is the only native representative of the family in eastern America. It is a graceful and very hardy shrub, a native of the mountains of Virginia and Carolina. It is in every way a smaller plant than *B. vulgaris*, which it otherwise closely resembles, except that the teeth of the leaves are less bristly pointed and the racemes are fewer flowered; the berries are oval, while in the European plant they are oblong. It is a perfectly hardy plant, which will grow wherever the common Barberry will thrive.

Berberis Sinensis, a native of northern China, is one of the most ornamental of the whole genus, especially when the fruit is ripe. It is a graceful plant, four or five feet high, with long, slender, flexuous branches, quite loaded at this season of the year with slender racemes of small yellow flowers. The leaves are small, spatulate or linear obovate and quite entire, or on young plants with scattered teeth; the fruit is the largest and most brilliant in color produced by any Barberry in the collection, while, unlike *Berberis vulgaris*, the foliage turns in autumn to brilliant orange and scarlet.

Berberis emarginata is a Siberian species, and one of the latest to flower in the collection. It has lanceolate-obovate, ciliate serrate leaves, and racemes of pale flowers. It is worth general cultivation for the beauty of its autumn foliage, which far exceeds that of any of the Barberries here in the brilliancy of its coloring. There is a very distinct variety of the common Barberry in the collection from Afghanistan, with stout erect branches, and spatulate leaves four or five inches long, borne on long, slender petioles; and another from Hakodate, in Japan, with bright coriaceous leaves, and pale flowers in semi-erect racemes.

Berberis umbellata, a native of the Himalayas, is a very distinct late blooming species, quite hardy here, and of no little ornamental value. The long, graceful, sparingly leaved branches are bright red, as are the slender three-parted spines, slender peduncles and pedicels. The peduncles are erect, three inches long or more and twice the length of the obovate-oblong, entire or slightly toothed, mucronate leaves, which are dark-green above and pale on the lower side; they bear near their summit a racemose umbel of long-pedicel, large, pale yellow flowers. The upright, umbellate inflorescence is quite unlike that of any other Barberry in the collection. *Berberis Cretica* is still later in bloom. It is a species from Asia Minor and quite hardy here. The drooping racemes of pale yellow flowers are rather shorter than the oval, entire or somewhat serrated leaves. It has stout, erect stems, three or four feet high, armed with short three or five branched spines, and soon forms a dense compact mass of handsome, dark-green foliage. It is well worth general cultivation.

Berberis concinna, a beautiful and very distinct little species, is also in flower. It was discovered many years ago in the Lachen Valley of the Sikkim-Himalaya, at an elevation of 12,000 to 13,000 feet, by Sir Joseph Hooker, who introduced it into cultivation, and who published a description and figure (t. 474) of it in the *Botanical Magazine*. It does not, however, seem very well known in gardens, and was not included by Lavalée in the catalogue of the plants in the *Arboretum Segretzianum*, or by Mr. Nicholson in his excellent "Dictionary of Gardening." *Berberis concinna* is a small, low bush, with erect or spreading bright red branches, one or two feet high, armed with

slender three-parted spines, and covered with small, spinulose-toothed leaves, one-half to three-quarters of an inch long, dark glossy green on the upper side, snowy-white and glaucous below. The pedicels are longer than the leaves, drooping, solitary and one-flowered. The flowers are globose, pendant and deep yellow in color. The fruit, which is described as large, oblong and bright scarlet, has not been produced here. *Berberis concinna* appears to be perfectly hardy here, a fact which would seem to indicate that many of the plants of the high Himalaya region may, with proper precautions in the way of protecting young specimens until they are fully established, be made to contribute to the beauty and interest of American gardens. This little Barberry is certainly a gem among dwarf flowering shrubs, and for the beauty of its foliage alone it should find a place in every rock-garden or on the borders of every shrubbery.

One of the most distinct and desirable of exotic Thorns is a north China and Magnolia species, *Crataegus pinnatifida*, common in the neighborhood of Peking and often cultivated by the Chinese. It is a variable plant, especially in the size and color of the fruit and in the character and amount of the pubescence on the leaves and young shoots. Here it is a small bushy tree, with dark green, shining, deeply cut and serrate, oval leaves, two to three inches long by half as much wide, borne on long, slender petioles. They are slightly rufous-hairy on the under side along the mid-rib and on the long slender pedicels of the large flowers. This species is handsome at this season, when the pure white flowers make a beautiful contrast with the rich shining foliage; but it is even more showy in autumn when it is covered with its large, scarlet fruit. This Asiatic Thorn is perfectly hardy here, and like all the north China plants which have been tried in the Arboretum, it seems admirably suited to the climate of the Northern States.

Caragana spinosa is a slender shrub, a native of Siberia, with handsome, yellow, pea-shaped flowers, and long, flexible, graceful branches, upon which the adult petioles, developed into long, strong spines, are persistent. The leaves with two to four pairs of linear, glabrous leaflets, and spiny stipules, are small, pale green and rather inconspicuous. This is a very hardy plant, recommended as a good subject to use in making dwarf impenetrable hedges, a purpose for which its long branches and long, stout thorns seem to well adapt it.

Caragana pygmaea and a variety with pendulous branches known as *C. pygmaea gracilis* are pretty little shrubs, one or two feet high, with slender spiny branches covered with small leaves composed of two pairs of linear, glabrous leaflets approximating near the end of the short petiole, and handsome large solitary yellow flowers. *C. pygmaea* is a native of Siberia and has long been known in gardens, although rarely seen in those of this country. It is perfectly hardy.

Syrax Americana is one of the most graceful of North American shrubs, and when the slender branches are covered with its drooping, pure white, bell-shaped flowers, borne in slender axillary racemes, few plants will compare with it in delicate beauty. It is rarely cultivated, however, and little known in gardens. Although a southern plant, not being found growing naturally north of Virginia, it is quite hardy here and blooms freely every year. It is a common plant along the margins of swamps and in low ground, where it reaches a height of from four to eight feet.

Attention has been called in earlier issues of these notes to the value of *Hudsonia ericoides* as a dwarf rock-garden plant. The second of our northern species, *H. tomentosa*, is equally attractive in the garden. It is a dwarf, hoary plant, only a few inches high, with narrow leaves, closely pressed and imbricated on the stems, very common on the sea-shore of the New England and Middle States and on the shores of the Great Lakes. Every morning during the blooming period of two or three weeks the plant is covered with a sheet of golden-yellow flowers, from which the petals fall by two o'clock in the afternoon, fresh flowers opening each day. This plant, like the other species, requires some care before it is thoroughly established in the garden, but once established, it will spread rapidly, and soon make a broad, handsome carpet.

Stephanandra (from two Greek words signifying crown and male, in allusion to the disposition of the stamens) is a genus of two or three Japanese shrubs, with the general habit and appearance of Spiraea, to which they are closely related. *S. flexuosa*, introduced a few years ago by the Messrs. Veitch, is the only species in cultivation. It has slender, flexuous branches, which here attain a height of three or four feet, with incised or lobed, cordate, ovate leaves, often colored with purple, and compound racemes of small white flowers. This is a graceful and handsome shrub, which is not very hardy,

however, here, even when carefully covered, and the stems are often killed back to the ground, but grow up again vigorously. It is now flowering on such stems as were not killed during the winter.

The Stagger-Bush (*Andromeda Mariana*), a native shrub, found along the Atlantic seaboard south of Rhode Island, in low, sandy, wet situations, and very common and covering extensive tracts in some parts of Long Island, is now in flower. It is one of the handsomest of the Andromedas. It attains a height of two to four feet, and has deciduous, rather coriaceous, and shining oval leaves, and large, pure white, bell-shaped, nodding flowers, in clusters, from axillary buds, crowded on the naked branches of the preceding year. The foliage of this plant is popularly supposed to poison browsing animals. It is easily cultivated, thriving best in deep loam mixed with peat, and is perfectly hardy. Its near ally, *Leucothoe racemosa*, a common plant, found near the coast in damp thickets from Massachusetts far south, is also in flower. Less showy than the last-named species, it makes in cultivation a neat, compact shrub, with erect, rather rigid branches, covered with oval-lanceolate, bright shining leaves, and erect racemes of small, cylindrical, pure white flowers. It will flourish in peaty loam, and grows and spreads rapidly.

The great Flame-colored Azalea (*Rhododendron calendulaceum*) is in flower, rather later than most of the garden hybrids, in which its blood is mingled, and which do not surpass it in the splendor of its orange and flame-colored, odorless flowers. It is a common shrub in the Alleghany forests from Pennsylvania southward, where it often grows in great masses, lighting up, at this season of the year, the lower slopes of the mountains with sheets of flame. It is quite hardy in cultivation here. No North American plant surpasses it in brilliancy of bloom, and few are better worth a conspicuous and permanent place in the garden where the soil is suited to its wants. Limestone is fatal to it, as it is to all Rhododendrons.

Rhododendron punctatum, the smallest of the species of evergreen Rhododendrons, which are found in the Alleghany Mountains, is in bloom. It is a graceful shrub, with recurved or spreading branches and narrow leaves four or five inches long, covered, as is the whole plant, with scurfy, resinous scales. The rose-colored flowers, nearly an inch long, in lax, few-flowered clusters, are developed later than the shoots of the season, among which they are almost hidden. This is, therefore, a much less showy plant when in bloom than the hybrids, or varieties of *R. Catawbiense*, in which the new shoots from the base of the terminal flower-bud are not developed until after the flowers have expanded. It will never, therefore, be a very popular plant in gardens.

The Alpine Rose (*Rhododendron ferrugineum*), a dwarf species, rarely a foot high, from the high mountains of Europe, with minute, dark green, shining, evergreen leaves, thickly beset on the lower side with ferruginous dots and beautiful bright scarlet flowers, is in bloom. This is a hardy plant, well suited to find a conspicuous place in the rock-garden, and, from its many associations, one of the most interesting of the European shrubs. A good covering of Pine branches in winter will protect the foliage from burning, and insure better and more abundant flowers.

Ethionema coridifolium is a pretty little plant from Asia Minor, which does not attain a height of more than six or seven inches, and with only the lower part of the stems really woody. It has minute, pale, glaucous, crowded leaves, and terminal, crowded racemes of bright, rosy, lilac flowers. It is very hardy and an excellent rock-garden plant. *Ethionema* (from two Greek words signifying scorch and filament) is a genus of the Mustard Family (*Cruciferae*), distinguished by its winged and toothed stamens. The other species, of which there are two or three, are annuals and perennials.

Lonicera oblongifolia is one of the dwarf Bush Honey-suckles of the northern United States, which is worth a place in the garden. It has slender, upright branches, four or five feet high, oblong leaves, and rather large pale yellow flowers on long, slender peduncles, the corolla deeply two-lipped and fully half an inch long. It is found in cold, deep bogs from northern New York to Wisconsin and far northward. It takes kindly to cultivation here, however, and thrives in ordinary garden soil.

Spiraea corymbosa is a dwarf species of the Alleghany Mountains, found from Pennsylvania to Virginia and Kentucky. It grows to a height of one or two feet, and has pale, oval leaves, cut-toothed towards the apex, and large, handsome, terminal, compound corymbs of white flowers, which are now just expanding.

Jamesia is a genus of the Saxifrage Family, which commemorates the labors of Dr. Edwin James, who, when surgeon and

botanist to Long's Rocky Mountain Expedition in 1822, discovered in the mountains of what is now Colorado, the only species.—*♂. Americana*. It is a perfectly hardy shrub, with slender, erect stems, two or three feet high, the young branches, as well as the peduncles and calyx, clothed with soft hairs. It has small, opposite, pale, serrate leaves, canescent on the lower side, and few-flowered, axillary and terminal cymes of pure white flowers, nearly a third of an inch across when expanded. Although not very showy, this is a good subject for a rock-garden or the margins of a shrubbery.

June 20th.

The Forest.

The Forest Vegetation of North Mexico.—VII.

TWO miles beyond Cusihiuriachic our road escapes from the difficulties of the cañon and mounts to the open plain at an elevation of 6,700 feet. Whenever on our drive from this point to the Sierra Madre we pass low ranges, or the bluffs of dry ravines, or of watered valleys, we find their slopes covered with Oaks, the species *Quercus grisea* (*Q. Emoryi* being left behind at this elevation), and, scattered amongst these, perhaps, a few Pine trees, commonly *Pinus Chihuahuana*, more rarely *P. macrophylla*, also. The Papigochic River, as the upper Yaqui is called, flows northward along the eastern base of the Cordilleras for a hundred miles, receiving the numerous streams that issue from their cañons, until a little below the town of Temosochic it turns abruptly to the west, cuts a gorge through the mountains, which has never yet been explored by man, and in a distance of about fifty miles to the plains of Sonora falls not less than 4,000 feet. As we follow its course to the ford near Tonachic ranch, coming up its eastern bank from the old City of Guerrero, we notice on the mountain-sides opposite us striking evidence of the severity of the drought, which prevailed over the plateau during the first half of the present year, in broad belts of dead Pines, which still hold their brown foliage. Our Mexican friends assure us that there was scarcely any snow on the mountains last winter, and that the little lakes of the plains, brimful of water as we now see them, were for months dried to the bottom. Coming to the ford we find on the low rocky hills and bluffs of the eastern bank both *Pinus Chihuahuana* and *P. mycophylla*, equally numerous with the Oaks; and above the bluffs of the western side on the edge of the plain stand the largest specimens of *Pinus Chihuahuana* that I ever saw, magnificent trees three or more feet in diameter and sixty feet in height. In this situation their roots find a deeper and more fertile soil than usual, yet having the drainage which they require.

Beyond the river and these wooded bluffs a few more miles of treeless plain, interesting, however, with its waving growth of grass in numerous species, and we enter an open forest of *Pinus mycophylla*, whose elevation is 7,000 feet, and whose level floor is hidden, not with shrubbery, but with grasses and other herbaceous plants. A little within the forest, at the abandoned site of a saw-mill, our wagon road comes to an end, and there, beside a clear stream which flows past the base of the first mountain bench, we rear our tent, turn loose our mules to revel for weeks amidst the luxuries and forage of the neighborhood, and ourselves proceed to explore the abundant and strange vegetation by which we find ourselves surrounded.

We see the mountain-sides everywhere deeply furrowed with cañons, some of which are walled high with rock, through all of which, now that the rainy season is passing, tumble noisy torrents. Through one of these cañons—one a few miles south of our camp—the *Arroyo Ancho*, or Broad Cañon, whose stream has cut quite through this outer range and drains valleys of the interior, leads a mule trail to Yoquivo and the villages and mining camps beyond, a lone mountain trail, seventy-five miles it may be, without a human habitation. Each divide between cañons

leads, by an exceedingly irregular course, perhaps, yet with unerring certainty, up to the summits five miles distant.

Climbing by one of these ridges to the highest ledge which frowns over our valley, the altitude of which, as indicated by an aneroid, is 9,875 feet, we scan with delight the plains and the jagged mountain chains, over which we have come, the latter appearing blue through the faint haze with their thin mantle of forests, evergreen Oaks and Pines, the former dotted frequently with gleaming lakes, and traced by streams whose course is made more plain by straggling lines of trees, Cottonwoods in the lower valleys and Pines and Oaks on the higher portions—a pleasant land, which might be a fruitful and a prosperous one but for the lack of rain sustained throughout the year; a region now held by a meagre population, who cannot safely plant their homes except along the rivers, and who maintain a precarious existence by growing, by the most primitive methods, after the deluge of midsummer rains, crops of Corn and Beans on their nearer lands and tending a few herds on the wide areas beyond.

Looking north and west and south we behold, however, only a sea of mountains, none appearing loftier than the one upon which we stand, everywhere covered with forests, noble forests of Pine crowning broad summits, dense growths of Pine and Spruce and Oak shading the northern slopes and darkening the valleys and cañons, and even the dry ridges and sunnier slopes hidden under close growths of the more dwarf species of Pine, Oak, Juniper and Arbutus. This is the great forest of Mexico, a belt 50 to 100 miles in width and 800 miles in length, the chief source in the future development of this country of its lumber supply, then to be brought out by railroad trains, not, as we saw all along the road by which we traveled, on the backs of donkeys and mules, or, at best, in the ponderous carts of the country, with wheels hewn from trunks of trees, and drawn invariably by three pairs of oxen.

C. G. Pringle.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—Not long ago I visited a green-house where a wonderful display is made of old and common plants all developed into well grown specimens. The high back wall was covered with the galvanized wire netting now so cheap and so well adapted for training plants; it was well covered with plants not commonly considered as climbers. The first in the row was a specimen of the old Oak Leaf Geranium, *Pelargonium quercifolium*, which was six feet high and nearly as many broad, though grown in an eight-inch pot. It was completely covered with clusters of bright purple flowers, and was really a revelation of beauty to one who had not thought of the ornamental capabilities of this plant. Then came a specimen of *Abutilon vexillarium* (*Mesopotamicum*) covering about fifty square feet of the trellis, and hung with countless red and yellow flowers. I learned, for the first time, what an admirable plant it is when well grown. *Asparagus tenuissimus*, in another place, wandered uncut, with shoots ten to twelve feet long, adding a feathery fringe to the *Abutilon*. Then came *Fasminium grandiflorum*, filling the air with its odor, and finally, at the end of the table, the much neglected climber, *Lophospermum scandens*, covering a large space with the cheerful green of its foliage and its wealth of rosy-purple flowers. On the centre table were Fancy *Pelargoniums* and *Fuchsias*, such as were seen at horticultural exhibitions before the Ferns and tropical plants absorbed all the space. The *Pelargoniums* from last fall's cuttings, and in ten-inch pots, were masses of bloom, four feet high, and so sturdily grown that no cluster of stakes was needed to support them, while the *Fuchsias*, from January cuttings, were pyramids five feet high and loaded with flowers. The only plant in the way of a novelty was a large specimen of the double white *Petunia*, Mrs. Dawson Coleman, which promises to be a great plant for florists' use in summer. In another house was a collection of *Begonias* of various sorts, all given space for full growth. Here were a *Begonia coccinea*, six feet high and four feet in diameter, covered with flowers from bottom

to top, *B. nitida alba*, nearly as large, with flower clusters as large as a man's hat, and *B. Rex* in many varieties, in eight-inch pots, with such a massive growth that I could not clasp hands around them. In this house the wire trellis on the back wall was covered with *Smilax*, which filled the air with the delicate odor of its flowers. A fine plant of *Clerodendron Thomsonæ* in a border at one end is intended to take the place of the *Smilax*, and an immense *Bougainvillea glabra* grows enormously, but has not yet bloomed well. The intention is to root-prune it and build a wall across the border, so as to confine its roots and insure its being kept dry in winter. If this is done it will probably next spring make an object worth going a journey to see.

I will not take space to write of the *Allamanda*, *Bignonia venusta* and other old-fashioned plants that were flourishing in roomy quarters, but it occurred to me that the skill of the true gardener was shown as effectively in producing noble specimens of common, though beautiful, plants, as it would have been in coddling a vast and crowded collection of diminutive novelties.

Albemarle County, Virginia.

W. F. M.

To the Editor of GARDEN AND FOREST :

Sir.—To the "Notes from the Arnold Arboretum," in GARDEN AND FOREST for May 30th and June 6th, permit me to add a few comments from a Western standpoint.

While the description of the fruit of *Ribes alpinum* as "large, handsome, scarlet, insipid" will apply perfectly to the wild mountain form, it does not describe the cultivated varieties found in gardens throughout eastern Europe. At the agricultural college near Moscow, Mr. Gibb and I found large plantations of Dwarf Juneberry, and adjoining them quite as large plantations of red and black varieties of *Ribes alpinum*. The fruit of the Currants was nearly as large as that of the Juneberry, and we thought superior to it in sprightliness and flavor. We have distributed some of the cultivated varieties found at Moscow, Orel and Varonesh, Russia, and shall expect reports in the near future.

Ribes aureum makes a hoister and more fragrant shrub at the West than in the moist air of New England, but we have a variety which is stronger in growth, handsomer in foliage and flower, and, we think, better in quality of fruit than the species. This we received from Dr. Fischer, of Varonesh, as *Ribes palmatum*.

Bush Honeysuckles are, as a rule, at home in our climate. *Lonicera chrysantha*, *L. Xylosteum*, *L. nigra*, *L. Ruprechtiana* and the named varieties of *L. Tartarica*, such as *splendens*, *speciosa*, *grandiflora rubra*, *grandiflora alba*, *bicolor*, *luteo-virginalis*, etc., are specially fine in habit, and flower on our grounds. It may be of interest to note that some of the supposed varieties of the common Tartarian Honeysuckle seem to be derived from a fixed and distinct type of the species found in east Europe. To illustrate: We received from Professor Sargent in 1880 a packet of seed of *L. splendens*. From these we have grown over one hundred seedlings. While they vary in color of flowers from pure white to all shades of pink, the habit of growth, expression and shape and color of the leaves closely resemble the *L. splendens*. This, joined with the fact that we met with varieties like the *splendens* in habit of bush and size and color of the flowers, will favor our idea that all of our named varieties of the Tartarian Honeysuckle are not derived from the same primitive forms.

The primitive form of the flowering Almond of Siberia flowers with us profusely very early in the spring, and the blossoms seem to endure a temperature several degrees below the freezing point. Last spring they were loaded with beautiful pink blossoms in March when water near them was covered in the morning with ice half an inch thick, yet the flowers showed no trace of injury, and the bushes were well loaded with Almonds, from which we now have growing plants. We also have a pure white variety of the Siberian Almond that is almost perfectly double. These are valuable in the parts of the West where the common garden varieties do not stand the winters.

J. L. Budd.

To the Editor of GARDEN AND FOREST :

Sir.—The discussion of the alleged poisonous properties of the *Ailanthus* in a recent number of GARDEN AND FOREST calls to mind a circumstance that fell under my observation in northern New York. It was decided to remove an *Ailanthus* which stood near a dwelling, on account of the popular prejudice against the tree, and for the same reason it was found difficult to find a man who would undertake the job. Finally one was engaged and he spent a day in cutting the tree down, commencing among the branches. At night his hands and

face began to swell, his eyes became closed, and for several days he was confined to his house suffering severely.

The sap of the *Ailanthus* is probably as poisonous as that of the poison Oak and poison Elder, which belong to the same alliance. If this is so, it is reasonable to suppose that the pollen of all three affects certain persons in like manner. I knew a person to remove from a certain locality where *Rhus venenata* was abundant, on the advice of a physician, because at the season of its blooming he was always attacked with violent symptoms of *Rhus* poisoning. In Virginia and neighboring States the *Ailanthus* runs wild in old fields.

Jacksonville, Fla., June 11th, 1888.

A. H. Curtiss.

Periodical Literature.

In *Longman's Magazine* for June will be found an article by Mr. Frederick Boyle which is in some sort a continuation of the one on Orchids to which we called our readers' attention some weeks ago as having been published in the same periodical. This time Mr. Boyle's title is "An Orchid Farm," and the place to which it refers is the establishment of the Messrs. Sander at St. Albans not far from London—the largest and most famous establishment for the importing, growing and selling of Orchids in the world. The author modestly confesses that no words can give a full idea of it, much less a distinct picture of the treasures which it contains. Yet his words certainly give us a clear general idea of the extent of the place and of the business there transacted, and a brilliant if necessarily vague sketch of the surprising charms of its contents. These, in so far as beauty and variety go, will be easily imagined by all who are familiar with Orchids, yet the masses in which they are shown are almost inconceivable. When we read of twenty-four successive houses, all of them at least 180 feet in length and the narrowest 32 feet in breadth, some given over to the sorting of new arrivals and the early stages of cultivation, but most of them filled with growing plants, we begin to realize the exactness of the word "farm" as Mr. Boyle applies it. And when he speaks of one house devoted almost entirely to *Odontoglossum crispum* in which twenty-two thousand pots have been counted, and of another 300 feet in length which he saw filled full of *Cattleyas* and allied genera all in bloom, we begin to see why he hesitated over an attempt at description. Many such facts as these he gives us, together with startling computations as to the value of the contents of this or that house and the magnitude of the orders constantly received and immediately filled. He also describes how the immense consignments of plants from all quarters of the globe are daily received and dealt with—amid manifold dangers from lurking scorpions, centipedes and poisonous ants—and traces some of the processes of cultivation. And then he notes some of the more remarkable individual plants which the establishment contains. A *Lalia alba*, for example, which he saw, bore 211 blossoms, and a basket of *Lalia anceps* measured three feet across. A mass of *Catasetum* was lying ready to bloom just as it had been brought from a Guatemalan forest—four feet by three in diameter and eighteen inches thick; and a *Cattleya Mossiæ* measured, in solid bulk, not including its leaves, five feet in height and four feet in thickness. This, a single plant and not a group, is said to be the largest Orchid ever brought to Europe. It grew on a tall tree near the hut of an Indian, whose private property it was and who long refused all offers to purchase it, but finally succumbed to the attractions of a beautiful rifle added to those of a large sum of money. Following his Orchids into their native haunts, Mr. Boyle speaks of the regard in which they are held by the South American Indians and of the way in which they garland their lonely forest churches with thickets of bloom, any one of which would be a treasure to the European amateur. But it is impossible here even to hint at all the entertaining facts which Mr. Boyle has interwoven with his account of the famous "farm" at St. Albans.

After all, however, much as we may admire Orchids, there are other things which more nearly touch our hearts, and a perusal of such an article as Mr. Boyle's affects us somewhat as does a long stay in the hot-houses where they grow—we are glad to feel a breath of fresh air again, and rest our eyes on the simple greens of the temperate zone. Fortunately *Longman's Magazine* affords the reader a chance to do this, for following upon the Orchid article we find one called "In the Woodlands" by the Rev. M. G. Watkins. It has not the poetical flavor of many similar articles which appear from month to month in our own magazines, but is very charming none the less in its glances at the woods and flowers of England; and here and there it gives proof of a more acute perception of the artistic properties of trees than the

ordinary lover of nature often reveals. For this reason it may be read with profit as well as with pleasure, and we may echo the wish for America which the author earnestly expresses for England—that a School of Forestry may soon be established. In speaking of the advisability of beautifying country roads, and not only city streets, by the systematic planting of trees, he says that “in some parts of North America every citizen is compelled to plant a certain number of trees—say six or a dozen—at his marriage or coming of age.” We trust this may be true, but should like to be told of the exact locality in which the rule is in force, especially as the words “coming of age” strongly suggest that some English mind has invented a friendly fiction to our credit.

Notes.

Ripe Tokay and Muscatel Grapes were in the Yuma (California) markets as early as June 13th.

According to the *Santa Barbara Herald*, the crop of Pampas plumes will be heavy, and already buyers are offering to take them at good prices. Not infrequently the profit from an acre has reached the sum of \$1,000.

Cherry trees were sprayed with arsenites at the Ohio Experiment Station soon after the blossoms fell this spring, and the result was that very little wormy fruit appeared, while on check trees, where the spraying was omitted, the curculio did much damage. Analysis of fruit a week after spraying showed no trace of poison. Spraying with a solution of lime was also tried, but it proved much less effective.

After the funeral of the Emperor William, in Berlin, the wreaths and other floral devices which had been sent from all parts of the country were exhibited in one of the rooms of the Hohenzollern Museum. They numbered more than 2,000, and consisted not only of fresh flowers, but also of Palm and Laurel garlands, of arrangements of Immortelles and Edelweiss, of gilded Oak leaves, and of foliage simulated in gilded or silvered metal.

From the discussions at the late convention of nurserymen in Detroit it was evident that the majority of members did not approve of reducing the postage on “plants,” and objected to adding this word to “seeds, cuttings, bulbs and roots,” in the bill now before Congress. The argument was that sending small plants through the mail interfered with the prices that must be asked by agents, and a large proportion of the business of nurserymen was transacted through agents.

Professor Budd is experimenting on a large scale with seedlings from the Russian Apples which he has imported. A series of crosses between the Russian Apples and certain American varieties have been made and the crossed seedlings are now growing. Many pure seedlings from the Russian Winter Apples are also growing. The hope is that varieties may be secured which will endure the trying summers and winters of our north-west region, and, at the same time, have the good quality of some of the more tender kinds.

Both branches of the Philadelphia City Council have voted to include the historic Bartram Garden among the Small Parks to be established under the ordinance of which mention has been already made in these columns. This means that the land cannot now be sold for any other purpose and that it may be taken by the city whenever it may choose to appoint a jury to assess damages, or that it may be taken by any responsible body of citizens who ask the courts to name a jury for this purpose and agree to pay for the ground as the jury may estimate its worth, or as may be arranged with the owners without a jury. In case an association of citizens take the matter in hand the city would without doubt respect the wishes of the donors as to how the garden shall be cared for. If the city pays for it the garden will remain at the tender mercies of city officials, who cannot always be trusted to treat such a possession with either the reverence or the good taste which its importance demands. Still, that so much has been accomplished is a matter for gratitude, and thanks are due in an especial manner to Councilman Thomas Meehan, the Chairman of the Sub-committee on Small Parks, for his labors in this behalf.

The statement which has been going the rounds of the papers that the old Endicott Pear Tree, planted by Governor John Endicott about 1630 on his farm in Danvers, Massachusetts, was dead, has no foundation in fact. This venerable tree is still alive and in a fairly vigorous condition. It now resembles in habit a low, wide-spreading Apple tree. A few years ago the trunk was split by a storm, which caused it to lean over the iron fence which protects the tree from cattle; it

then sent up from below the split a strong, vigorous shoot, which gives it its present bushy appearance. This tree was never grafted, as suckers from it produce the same inferior fruit as the main branches. Another famous Pear tree, known in Salem as the “Orange Pear,” and supposed to have been planted about 1640, is still alive and flourishing in a garden in that town. The soil and climate of Essex County seem favorable to longevity in Pear trees. The “Cogswell Pear Tree,” in the Town of Essex, is more than two centuries and a half old. John Cogswell brought the seed which produced this tree from England in 1635. This tree, which stands in the open field back of Mr. Edward Lee’s house, near the foundations of John Cogswell’s first house, still bears fruit, which is used for preserving.

Retail Flower Markets.

NEW YORK, July 6th.

Roses continue scarce, and are of poor quality. So rare indeed are all good flowers that all choice bouquets are set off with Orchids. Paul Neyrons are best of the Hybrids. American Beauties are very small and one-sided. Selected Hybrids are almost too poor to use, and cost \$3 and \$4 a dozen. Maréchal Neils and General Jacqueminots arrived in small lots from Newport. They cost \$1.50 a dozen. La France Roses are scarce and small. They cost \$1 and \$1.25 a dozen. Lily-of-the-Valley sells for winter prices—\$1.50 a dozen. There is little of it unless to order. *Lilium longiflorum* and Callas cost \$3 a dozen. Gladioluses, \$1.50; Pansies, 25 cts.; Buttercups, 35 cts., and Daisies from 15 to 20 cts. Pea Blossoms cost 25 cts. for a small cluster. Mignonette is of bad quality and in light demand at 25 cts. a dozen. Peonies are out of bloom. Florists receive plenty of steamer orders, but really have not the flowers to fill them. For the dinner given at Delmonico’s to the Duke and Duchess of Marlborough the favors ordered were not supplied, because it was impossible to get any Roses. Tamarisk foliage is used with good effect in tall designs.

PHILADELPHIA, July 6th.

Good flowers, and especially good Roses, were never less abundant than they now are. True there is little demand for flowers at this dead season. The “Commencements” are all over, and most of the flower-buyers are out of town. During recent years flowers have been used with less profusion at school commencements, but this year a decided improvement was noticeable in the demand, and certainly there are few occasions where they can be more appropriately used. Sweet Peas are still asked for, and are in fair supply. Zinnias are becoming more plentiful, and are catching the public fancy, owing to the improvements in them within the past few years. The tints and shadings in some of the flowers, though over showy perhaps, are really very beautiful and distinct. Rudbeckia may be obtained in limited quantities from the fields. It is figured in a recent number of *The Art Interchange*, and labeled “The Black-eyed Susan!” without any indications of its botanical name. It is frequently called the “Cone Flower,” and sometimes the “Buckeye Daisy.” Carnations, excepting white varieties, are fairly plentiful, and sell at 25 cts. a dozen. Sweet Peas, Zinnias and Rudbeckia also sell at same price. There are some few Mrs. John Laing Roses to be had at \$1.50 a dozen. Meteors, though not at all plentiful, cost the same. La France, Mer-mets and the Bride cost \$1 to \$1.50. Perles and Sunsets, 75 cts. to \$1. The demand for *Asparagus tenuissimus* and Smilax has fallen off considerably, though there is very little change in the price. A few flowers of that pretty wild pink Orchid, *Calopogon pulchellum*, are brought from New Jersey, and sell at 50 cts. a dozen. The orange-colored *Polygala lutea*, from the same State, are offered at 25 cts. a dozen. The two latter flowers have not been noticed in this city before. They will remain popular as long as they are in season.

BOSTON, July 6th.

The month of July is the duldest in the year for the florist. School graduations and social gatherings, which make a demand for cut flowers, are all finished; the fashionable season at the seaside resorts, which sometimes gives a little life to the business in midsummer, has not yet begun, and were it not for the “steamer days” and an occasional funeral, florists might as well lock up their shops. The season that has just closed has not been remarkable in any way; nothing striking or decidedly original has been introduced in the way of floral designs, and the only characteristic thing to say of the season is that it began late, and that the average price of cut flowers was considerably lower than ever before. Roses in midwinter were not up to the average either in quality or quantity, but otherwise the condition of the trade has been generally satisfactory. Among the best selling varieties at present, and in fact all through the season, are the Grace Wilder Carnations. It is a remarkable hold which this Carnation has taken of flower-lovers and buyers. The pink Pond Lily seems to be as popular as ever as a summer favorite. Gloxinias, Cornflowers and the golden Sweet Sultan are all among the popular flowers of this month. Out-door Roses are still plenty and cheap, the street peddlers handling the most of them. A few Sweet Peas and Asters are to be seen in the florists’ windows. There are no settled prices that are worth quoting. All is grist that comes to the mill just now, and no reasonable offer is refused.

GARDEN AND FOREST.

Water Lilies.

THERE are no plants perhaps which can be cultivated in the United States with less trouble and with more pleasure than Water Lilies; and certainly no plants create more admiration when they are seen in perfection.

The natural conditions here are peculiarly favorable to them. Shallow ponds with muddy bottoms in which the burning rays of our summer sun raises and maintains the temperature of the water to almost tropical heat, are common in many parts of the country. Our native Water Lilies flourish in such ponds, which may be made the home, too, of numerous hardy exotic species, and in which gorgeous tropical varieties may be set to flower during the summer months. Tropical Water Lilies are grown in heated tanks, too, under glass in some gardens; and they are often grown in out-of-door tanks which can be heated by pipes from the green-house boiler, if the tenderest species or very early flowers are wanted. Some of the finest varieties can be as successfully grown in a tub of water sunk in a city yard as in the most elaborately constructed and heated tank; and tubs of these plants plunged in the basins of fountains make the most appropriate and by far the most beautiful ornaments which can be used in such situations. Water Lilies are plants for the poor as well as for the rich; and their decorative capabilities are almost limitless. The number of species with handsome flowers is already large, and as several species hybridize freely, it is probable that we cannot form an idea even yet of the beauty which intelligent cultivation will develop in these plants.

The true Water Lilies (*Nymphaea*) may be divided into two classes: those which expand their flowers in the morning, closing them in the afternoon, and those which bloom only at night. Among those of the first class, none is more lovely than the common fragrant White Lily of the Eastern States (*N. odorata*). Its pure white, deliciously fragrant flowers are not surpassed in delicacy and in real beauty by any of the more highly colored and showier flowers of the tropics. This plant is very easily established in muddy, shallow ponds by simply pushing bits of the

root down into the mud, and it is one of the best Water Lilies to grow in a tub, when if planted in very rich soil it will produce an abundance of flowers all summer long. In the autumn the water should be turned off and the tub stored in a cellar or pit out of the reach of hard freezing. There is a pink flowered variety of the common Water Lily found in a pond in the town of Sandwich in Massachusetts. The flowers are much esteemed and sell for high prices, although really far less beautiful than the white ones. It is as easily cultivated as the typical plant; and when transplanted into other ponds it still produces its pink flowers. *Nymphaea tuberosa*, a native of the region from western New York to the Mississippi, where it inhabits shallow ponds and sluggish streams, is a handsome species with tuber-bearing roots, large bold leaves and pure white flowers, sometimes ten inches across. They are quite devoid of odor, however, and although this is a very hardy, free-growing plant, soon spreading over large areas, it has not the charm and will never supersede its humbler eastern rival. The yellow flowered Water Lily of Florida is hardy too at the north, and will flower abundantly if a warm situation and deep soil are selected for it. It is not a very showy plant, however, and the interest which it excites lies in the pale yellow color of the flowers (an unusual color in Water Lilies), rather than in their beauty, and in its history. For years it was only known by the picture joined to one of the plates in Audubon's "*Birds of America*," while its existence was doubted and denied. This sketch was made by the lamented naturalist, Leitner, one of the first victims of the Seminole war, and it is only within recent years that it was made known to botanists through the exertions of our associate, Mrs. Treat, by whom and by Mr. Curtiss it was introduced into cultivation. An interesting article from Mrs. Treat's pen, in which the finding of *N. flava* is described, was published with illustrations in Harper's Magazine, volume 55, page 365.

The European Water Lily (*N. alba*) is hardy in the Northern States, as are its varieties *N. alba candidissima* and *rosea*. The first of these varieties is the most beautiful of the European Water Lilies. It has large, pure white flowers with more waxy petals than our common Water Lily, and when grown under favorable conditions of soil and temperature it produces its flowers during a longer period. They are quite odorless, however, and these plants will probably never be cultivated here except by persons who desire to form a general collection. More attractive is the dwarf Water Lily of China and Siberia (*N. pygmaea*)—a hardy plant with miniature fragrant white flowers which remain open only during the afternoon.

The number of tropical Water Lilies is large. A few of them can be grown in the Northern States in artificially heated tanks only, but some of the finest flower freely in shallow ponds if they are started in heat and then transplanted into large boxes or tubs of rich soil, which should be plunged, when the water has become warmed by the sun, without disturbing the roots. Many of these too make excellent tub plants, producing flowers profusely through August and September.

The Victoria Regia, first cousin of the *Nymphæas*, the great Water Lily of the Amazon, although generally grown under glass outside the tropics, will, if treated as an annual, and started in early spring in heat, flower at the north in an open heated tank, and produce its enormous leaves and great white flowers in luxuriant profusion. In the Southern States it needs no artificial heat to develop its beauties; and we may expect to see, when it is better known, the sluggish streams of Florida and Louisiana become splendid by the presence of this, the noblest of all aquatic plants. Some idea of the beauty which may be given to southern ponds and streams through the cultivation of Water Lilies can be learned from our illustration (see page 245), taken from a photograph of one of the small lakes in the famous botanical garden at Buitenzorg, in the mountains of Java, upon which the Victoria Regia

and several of the larger tropical Nymphæas are floating, while in the foreground there is a great mass of the Indian Lotus.

Among tender Water Lilies which flower by day by far the best known in our gardens is the blue-flowered species from the Cape of Good Hope, *N. scutifolia*. It is a handsome plant, with bright blue flowers, and very easy to cultivate. In gardens it is sometimes confounded with *N. cœrulea* or *N. cyanea*, synonyms of the tropical African *N. stellata*, which the ancient Egyptians prized so highly and so often engraved on their monuments. Another blue-flowered Water Lily, which is probably only a variety of this last, is known in gardens as *N. Zanzibarensis*; it has larger and darker flowers, and is one of the finest and very best of all the Water Lilies in cultivation. Varieties are known with darker and with lighter flowers.

Among tender Water Lilies which flower at night are *N. Lotus*, an old world tropical species, with large, pure white or sometimes red flowers (*N. rubra*). It is the Lotus sacred to Isis, and famous among the Egyptians, who, in spite of its sacred character, made bread from its seeds and dried roots. It is one of the first of the tropical species cultivated in Europe and one of the handsomest. It is a parent of many hybrids, of which the most showy and the best known is *N. Devonensis*, one of the triumphs of English horticulture; and hardly surpassed in the brilliant color of its large flowers by those of any other Water Lily. *N. rubra* and *N. dentata*, now considered forms of *N. Lotus*, although quite distinct from a garden point of view, are exceedingly attractive plants, and this is true of the Jamaica Water Lily (*N. ampla*), with its yellow or yellow-white flowers. There are many more of the true Water Lilies in the tropics, but it is unnecessary to enumerate them here.

But the Nymphæas are not the only aquatic plants with attractive foliage and handsome flowers, and no collection of these plants will be complete without their near relatives, the Nelumbiums, the Sacred or Water Beans, with their broad, circular leaves, borne above the water on tall, stout petioles, and great, fragrant flowers, standing high above the leaves. There are two species, the yellow Nelumbium (*N. luteum*), a native of our Western and Southern States, and now naturalized in a few places in the East, notably in the Connecticut River below Hartford, and in the Delaware below Philadelphia, and in New Jersey. The American Nelumbium has handsome yellow flowers, sometimes ten inches across, and farinaceous tubers, which, like the seeds, are edible, and once furnished to the North American Indians an important article of food. The second species, *N. speciosum*, is a native of India. From time immemorial it has been looked upon as the emblem of fertility, and has been cultivated by the Egyptians and all the people of the East. It is the Egyptian Bean of Pythagoras and the Sacred Lotus of India. The lovely, delicate white, sweet-scented flowers, tipped with pink, which in one variety are pure white, stand high above the pale green leaves, and are not surpassed in beauty by those of any other plant. It is easily cultivated, and the fact that it has already become thoroughly naturalized in one pond at least in New Jersey excites the hope that this fine plant will some day be as much at home in the waters of the Middle and Southern States as it is in those of China and Japan. At the North it should receive the treatment necessary to insure the blooming of the hardier of the tender Nymphæas, although its more vigorous growth and rambling habit demand a separate compartment when it is grown in a tank with other plants, which otherwise it would soon exterminate.

The list of aquatic plants with handsome flowers and foliage is not by any means confined to the Nymphæas and the Nelumbiums, but enough has been said, perhaps, to draw attention to the pleasure which may be derived from the cultivation of this class of plants which are within the reach of any one who can afford a tub of water and a piece of sunny ground large enough to hold it.

The Artistic Aspect of Trees. III.—Color.

THE forms and the textures of trees having been briefly noted as they appear from the artistic point of view, it is time to say a word about their colors.

The color of foliage is more or less affected by its texture. Given leaves of a certain tint of green, the tree will seem darker if its head is massive and dense than if it is feathery and infiltrated with light. It is, of course, the general color effect, and not the color of a leaf separately considered, which concerns the student of nature's beauties and of the planter's tasks.

Among the varieties which nature creates when clothing her trees in her usual livery of green, an artist would distinguish varieties of tint and varieties of tone or "value." The green of foliage may be of a bluish, or a yellowish, or a grayish tint, and, keeping this tint, it may vary from a very pale to a very dark tone. Again, the effect of a tree may be compounded of the different colors shown by the different sides of its leaves—may be a mottled and not a simple tone; and it is always affected by the surface-character of the leaves, a smooth and shining tissue giving a tone quite unlike that produced by a dull or woolly tissue, even though upon examination the same shade of coloring matter be discovered. And then, when her greens are exhausted, nature falls back upon other colors and gives us such an eccentric thing as, for instance, the Purple Beech.

If, as we have said, it is impossible to learn how to appreciate and manage the forms of trees from written rules and counsels, it is still more impossible thus to learn with regard to their colors. Among artistic powers a feeling for color is the one which depends most upon an innate gift; and, though like all the others, it may be cultivated with success, a process of practical self-culture—of constant observation and comparison and appraisal—is the only one that can much avail. The trouble with most of us is not that we could not see the difference between harmony and disharmony in colors if we tried, but that we do not try. We do not really look at what we see. We accept what nature—and too often what the planter—sets before us, and neither reflect whether it is good or bad, nor stop to analyze the reason even when we are quite sure which it is. Although, however, reliance must chiefly be placed upon the cultivation of eye and taste, whether the aim be appreciation merely or action too, a few general principles may be explained in words.

As with qualities of texture, so with qualities of color, restfulness and dignity are more often desirable, and are desirable in larger quantities, than restlessness and fragile grace; and it may be broadly said that dark colors are more dignified than pale ones, and that the most restless of all are those which are mottled instead of simple. The unquiet look of a Silver Maple, for instance, as compared with the restful look of a Sugar Maple, depends as much upon the varying color of the under and upper surfaces of its leaves, as upon their more lace-like shapes and the more straggling form of the tree itself. The former is the better tree of the two to supply a lively accent in some situation where this is desirable; the latter is the better to use in large masses, or to place as a single specimen where a strong yet quiet note would be the right one.

A second point which may be indicated is that it is safer to place two tones of the same tint together—as a dark and a lighter bluish-green—than to associate two different tints—as a bluish with a yellowish green. Yet the most effective combinations, when they are rightly made, are those which owe their charm to contrast rather than to concord. Still another point is that grayish greens are those upon which dependence may best be placed for harmonizing strong notes of other kinds—approaching most nearly to those neutral tones upon which

painters on canvas put such reliance. We may sometimes see the fact illustrated towards evening, when a plantation which is inharmonious in color under bright light becomes harmonious simply by the fading out of one or two of its tints into grayish twilight hues.

Again it may be remarked that when a tree is not green at all—when it is purple, for instance, like the well-known variety of Beech, or red like some of the Japanese Maples, or blue like the Colorado Spruce, or bright yellow like many cultivated varieties of shrubs—it should be used with peculiar care and a discretion amounting to the most rigid parsimony. It is like the red cloak which the landscape painter is so fond of using—invaluable, sometimes, if set in exactly the right place, but by no means always desirable, and always ruinous if wrongly placed or over-emphasized. Finally, all objects which come in visual contact with our trees must be considered as affecting their own colors. A tree which would look well against a background of dark rock might not look as well lifted against a background of sky; and one which would harmonize with a brown or a white house might not harmonize with a red brick house. The sheen and color of water, too, and its reflecting powers, demand that its borders be very carefully treated. A bright tree which gives a welcome accent in itself might give a distinctly over-emphatic accent if doubled by reflection in a sheet of water; and, in general, moderately dark, or grayish, or whitish trees best sustain this reflection. We are right, for once, in our fashion of placing Willows near water; not only their feathery texture but their tender and often neutral colors fit them well for such situations. If we imagine a large White Willow changed to a vivid yellow-green, like that of the Box Elder, we feel at once that its fitness for the neighborhood of water would be seriously impaired. Of course in the autumn the case is different; then all tones are changed to more vivid ones; brightness is the characteristic quality of the landscape, and the brighter the reflected note, the better it often appears.

It should also be remembered that the color of its foliage is not the only thing which determines the color of a tree. Its trunk and branches are often very apparent and are sometimes very striking in color. The foliage of the Canoe Birch would not, of itself, make it a very conspicuous tree, but its dark glossy leaves with their paler under sides, in contrast with its pure white bark, make it so very striking that it is difficult indeed to place it harmoniously. The lighter hue of the foliage of the Silver Birch is also accentuated by the whitish-gray of its bark, as the mottled appearance given the Sycamore by the shape and disposition of its leaves is accentuated by the mottled color of its splitting and peeling bark. There is no end to the varieties of combination thus presented for the planter's use, and while each one renders his task more complicated and difficult, each affords him a new chance for some specially beautiful effect if he can learn how to use it rightly.

Among the Pines in June.

THE Pines in June are fairly ablaze with color. Gorgeous masses of broad-leaved Laurel forming dense thickets, are scattered here and there, and the intervening spaces abound with the showy Dogwood (*Cornus florida*), and wild roses fill the air with a delicate perfume.

The Japan Honeysuckle (*Lonicera Japonica*), has found its way among our native shrubs and threatens to strangle them. It extends over quite an area on either side of a small stream. I have watched its progress with much interest for ten years past, and to-day it is one mass of bloom, clambering over poison sumach and a great many other shrubs, and even large trees like the Sour Gum and Swamp Maple. Not one of our native vines can compete with it. Even the vigorous Ampelopsis is hidden beneath this wealth of foliage and flower.

The Cinnamon-fern (*Osmunda cinnamomea*) grows here in great luxuriance. The sterile fronds are above my head, standing out in graceful curves, perfect in outline, with not a broken or straggling frond. Such a magnificent bunch growing near our door would well repay the time and labor bestowed upon it. Our two other *Osmundas* are also here, as well as the two *Woodwardias*, and the sweet-scented *Dicksonia*, and several *Aspidiums*. The rare very local *Schizaea pusilla*, belongs exclusively to our Pine-barrens. I find it a few miles from home surrounded by many other choice plants—*Pogonia divaricata* and *P. verticillata* being among the number.

Our ponds and streams are now beautiful with white Pond Lilies, and the little Lake-flower (*Limnanthemum lacunosum*), is scattered among them. It has small, shining, heart-shaped leaves, often variegated with white and yellow, and clusters of white wheel-shaped flowers are intermingled with the pretty leaves.

The Water-shield (*Brasenia peltata*) is also in the same pond, and its oval, shield-shaped leaves float among the Lilies and Lake-flowers. The flowers of the Water-shield are of a dull-purple color, and its stems and buds are coated with a thick, transparent mucilage.

The inflated Bladderwort (*Utricularia inflata*) is mixed with the other plants, floating on the water, and when free from them it goes where the wind wills it, with its cluster of bright yellow flowers standing above the water and carrying within its curiously formed bladders hosts of tiny larvæ and animalcules. The purple Bladderwort is here too with violet-purple flowers. The bladders on this are very abundant and quite unlike those of our other species. Under the microscope they are curious and beautiful objects.

The long-leaved Sundew (*Drosera longifolia*) is growing in the more shallow parts of the pond. This species more than our others, has the power of adapting itself to its surroundings. Some of the stems are more than a foot in length, with a cluster of purplish leaves raised above the water and covered with reddish bristly glands that exude a transparent, glutinous fluid which glistens in the sunshine like dew-drops. Many unhappy insects have been lured by the fascinating glitter and become hopelessly entangled among the bristles, and the leaves have rolled entirely around some of the victims. And for what purpose? It surely cannot be for lack of nourishment.

The Arrow-head (*Sagittaria*) grows along the margins of the pond. Some of the forms are very firm, with large, broad, sagittate leaves, which in other plants are simply lanceolate. The Arrow Arum (*Pellandra Virginica*) is in company with the *Sagittaria* as well as many other charming plants, and altogether the Pine Barrens are very far from being barren of beauty in these early summer days.

Mary Treat.

Window Gardening.

IN the summer of 1882 I attended in London the annual Flower Show of the Westminster Society for promoting gardening among the working classes.* The exhibition was held in tents located in the College garden of Westminster Abbey, and a band of music added to the attractions. A small admission fee was charged. Many of the plants were admirably grown, and would have been worthy of a prize anywhere. There was a large attendance of orderly people, many of them evidently of the poorer classes; also a large sprinkling of richer people. The most interesting event of all was the presentation of the prizes. On a platform in the open air a number of ladies and gentlemen might have been seen, among them Dean Bradley and the late Earl of Shaftesbury; the latter, as had been his custom for many years, presented the prizes. The fortunate ones came up one after the other to receive the awards from his hands; and it was a sight not soon to be forgotten. It was evidently a great pleasure for the Earl, for he had a pleasant look and a kind word for all, and especially for the children.

Hodder, in his "Life of the Earl of Shaftesbury," in speaking of the interest that the Earl took in this Flower Show,

*The late Dean Stanley was President of this Society.

says: "The flowers, humble and simple enough, breathed whispers of strange histories. Some were reared in furtive hours in crowded slums; some came from the work-house, and many from the parochial, national, infant, Sunday and ragged schools; some from the kitchens of domestic servants and the quiet homes of working people. The advantages of these flower shows in a social aspect were many. They provided a source of simple recreation, and gave a new interest in home by adding unwonted cheerfulness to the comfortless rooms of the poor. They became the means of drawing attention to some of the social wants of the working classes, such as the need of fresh air, ventilation and more space. They taught them simple habits of forethought and prudence, for if they would win the prizes they must purchase their plants long beforehand, and expend money and time on what might only be a probability of success. Their chief good was that in watching the growth and progress of the flowers under their care the children and their parents were brought into close contact with something pure and innocent and beautiful; something that should speak to the better part of their natures and tell them of Him who has made the earth beautiful and fair."

Lord Shaftesbury believed there was nothing among the secondary means of instruction for the people to surpass window gardening and flower culture.

The love of plants and flowers on the continent of Europe is perhaps more universal than in England even. Hurst, in his "Life in the Fatherland," says: "But while the universal pains bestowed by the affluent on plants of the rarest and most beautiful variety is admirable, the almost paternal care lavished by the poorest and humblest on such flowers as they can have is touching. The family that is crowded into a single story of a small house is sure to have each window, however small, occupied by flowers. They are healthy plants, too, for they seem to be always in blossom and the leaves are of the freshest verdure. In the narrowest streets and lanes, in town as well as country, there is a love of flowers and a skill in training them into thrift and beauty, confined to no class or condition, and exhibited alike by small children and very aged persons."

Many of these foreigners who come to this country bring this love of plant life with them. I have in mind a German woman in this city, whose plants are always the envy of the neighborhood. I asked her once how it was she succeeded so well when others failed under nearly the same surroundings. She said: "She did not know; only she thought she must love the plants better." I think this German woman was right in her conjecture. No one can expect to be a really successful grower of plants unless he really loves them. Who can read that charming story of "Picciola," by Saintine, without believing that a plant reciprocates the love bestowed upon it! This plant, prison grown and cared, became almost a human being in its power for good. Among the well-to-do classes in America the love of flowers is undoubtedly increasing year by year, and as a proof of this notice the large sale of flowers in the stores and on the street, and the flower-beds so carefully planted and watered by the occupants of the country house.

There is, however, need of an effort to spread a greater love of plants and flowers among the poorer classes. Largely it must be done through the children by example and education. The public and the Sunday school should do what it can in this direction. Something has already been done, notably in Boston, where many of the churches give pot plants to the children at Easter, and this custom is increasing. This seems far preferable to the old plan of giving only flowers, which so soon wither and decay. The plants also look very pretty as a decoration to the church. In one Sunday-school at least prizes have been offered for the best plants brought back the next Easter, thus encouraging the children to care for them during the year.

The Massachusetts Horticultural Society has for several years offered prizes for window gardening to children eighteen years old and under. The value of these prizes has ranged from 50 cts. to \$1.50. The effort of this Society to popularize the cultivation of flowers by encouraging children in the love and care of plants deserves high praise.

I am not aware that any other society has made any similar attempt. Something more, however, should, I think, be done by our Horticultural Society when the prizes are awarded. Why not distribute the prizes on an appointed day when the officers of the Society might be present; and why not select some competent person to address the children and present the prizes to each child personally? This, I think, would have an encouraging effect and stimulate them to greater efforts in the future.

Boston.

J. D. W. French.

Foreign Correspondence.

London Letter.

THE fortnightly exhibition of the Royal Horticultural Society held yesterday was an unusually full one, and the number of new and rare plants was larger than it has been for several meetings. This being now just the height of the Orchid season, there were many good things exhibited and not a few were submitted to the committee for certificates. Perhaps the loveliest of all the Orchids shown, certainly the rarest and most valuable, was *Cattleya Wagerii superba*, which may be best described as a white form of *C. Mossiæ*, a large bold flower, with broad sepals and petals and a wide shallow lip. The whole flower is pure white, excepting the large blotch of citron-yellow on the labellum, which, however, does not mar the chaste beauty of the blossom. This particular plant represented a much finer form of Wager's *Cattleya* than has yet been seen, the flower being larger and of better form, and fully justifies the additional name, *superba*. The specimen came from the unrivaled collection of Baron Schroeder and bore over a dozen flowers. Another Orchid that excited some interest and received a first-class certificate, was a new *Phalænopsis*, recently named *P. gloriosa* by Professor Reichenbach. It is, however, so much like *P. amabilis*, that one might easily mistake one for the other. In both the foliage is tinted with a purplish hue, and both have large white flowers, with the lip stained with vinous purple. It was exhibited by Messrs. Low, of Clapton, and their manager, Mr. Casey, tells me that it is a freer growing plant than the old *P. amabilis* and a much freer flowerer, and if this turns out to be the case everywhere, it is an acquisition, undoubtedly. Messrs. Low also showed a form of the new *Cypripedium bellatulum*, for which they received a certificate at the last meeting. The variety is called *roseum*, because the flowers are distinctly washed or stained with claret purple on their exteriors. Though I do not agree with the principle of certificating mere varieties that exhibit only a slight deviation from the types, I think that if this coloring in the flowers of this *Cypripedium* is constant, it will be a beautiful Orchid. The intimate relationship between *C. bellatulum* and *C. Godefroyæ* is as apparent as that between *Phalænopsis amabilis* and *P. gloriosa*, and many are of the opinion that the points of distinction, from a cultivator's standpoint, are weak. A fourth Orchid, certificated on this occasion, was an extremely fine form of *Odontoglossum nebulosum*, called *excellens*, exhibited by Messrs. Sander & Co., St. Albans. I have never before seen such a fine variety, the only approach being that named *pardinum*, which I remember seeing in splendid bloom in Messrs. Backhouse's nursery at York some time ago. The excellent variety has flowers fully a third larger than the type, with the broad sepals copiously marked with large spots of purple, which, not being confluent, makes the flower very pretty. The typical *O. nebulosum* is one of the finest of Mexican Orchids, and, in our moist climate, it can be grown to perfection. A remarkably fine form of *Odontoglossum Hallii* named *magnificum* won a certificate. The flowers are much above the usual size, and with broad sepals and petals and an extraordinarily wide labellum, while the colors, pale-yellow ground and coffee-brown markings, are richer than in ordinary *O. Hallii*. It was shown by Mr. Pollett an amateur, who owns a choice collection of Orchids near London.

A very beautiful new Japanese shrub was shown by Messrs. Veitch of Chelsea, to whom a first-class certificate was worthily awarded. This was *Syrax Obassia*, a dwarf shrub, having leaves of rounded outline as large as those of *Catalpa*, and bearing drooping racemes, six inches or more in length, of pure white flowers, resembling those of a *Philadelphus* or *Mock Orange*. Judging by the number of flowering branches exhibited, it must be a free flowerer, and it is certainly one of the most beautiful

Water Lilies in the Garden at Buitenzorg—See page 241.

shrubs that has been shown for a long time. It is said to be quite hardy in the open air in the Coombe Wood nurseries near London, hence it is a most valuable acquisition. Messrs. Veitch also showed flowering twigs of the pretty *Styrax japonica* (considered by some to be a form of *S. serrulata virgata*). The flowers of this species are white, also, and, as they hang thickly on the twigs, they remind one of our old favorite, the *Solanum jasminoides*. This *Styrax* is also hardy at Coombe Wood.

The hybridization of stove Anthuriums has been carried on in Belgium to a great extent, and has resulted in a multitude of hybrids, some few of which are excellent and decided improvements upon their parents. The principal species that have been used in hybridizing are *A. Andreanum* and the old *A. Scherzerianum*. One of these new hybrids was shown yesterday by M. Linden, of Brussels, and the committee gave it a first-class certificate. It is called *A. Desmetianum*, after one of the Ghent nurserymen. The plant is a good deal like *A. Andreanum* in growth, having similar heart-shaped leaves, and also a heart-shaped flower-spathe about four inches long, but, instead of being of the usual bright scarlet, it is of the deepest blood-red-crimson, a color not hitherto seen among Anthuriums. It is certainly a break from everything yet produced, yet it may be only a seminal form of *A. Andreanum*.

A new *Sarracenia* named *S. Williamsii* was shown by Mr. B. S. Williams and was certificated. It is a hybrid between the dwarf *S. purpurea* and one of the tall pitcher species, such as *S. flava* or *S. Drummondii*. The pitcher-

ers are about fifteen inches high, of massive size, and very handsomely shaped about the lid and mouth. They are of a cheerful apple-green, marked with a tracery of heavy crimson veins. Though we have such a large number of hybrid *Sarracenias*, there is certainly room for such a handsome sort as this.

W. Goldring.

London, June 13th.

New or Little Known Plants.

Amelanchier oligocarpa.*

ALL of the American forms of the Shadbush or Juneberry have long been grouped together as varieties of one species, *Amelanchier Canadensis*. Of late years the western species, *A. alnifolia*, which was figured in a recent number of GARDEN AND FOREST, has been recognized as distinct. A figure is now given of one of the eastern varieties which seems to be equally worthy of specific rank.

Unlike our common Shadbush, which is often found in dry, open woods, this is an inhabitant of cold swamps and mountain bogs, and is found only northward, from Labrador and Rupert's Land to Newfoundland, New Brunswick, northern New England and New York, and the shores of Lake Superior. It is a low shrub, rarely more than from two to four feet high, and the smooth

* *A. OLIGOCARPA*, Roem. Syn. Monog., iii. 145. A low bush; leaves oblong or rarely oblong-ovate, acute at each end, sharply serrulate, glabrous (somewhat pubescent when young); flowers one to four, long-pedicellate; petals obovate; fruit dark purple, obovate to short-oblong.

and mostly oblong leaves are acute at each end and usually very finely serrulate. The long-pediceled flowers are solitary or in pairs, or rarely three or four in a raceme. The petals are broad and obovate, instead of oblong or linear, and the fruit is large, dark blue-purple, with a heavy bloom, and often nearly twice longer than broad. It is sweet and with a more decided flavor than the ordinary Juneberry, which is globose and crimson or purplish red.

A word may be said in regard to the specific name which is here adopted, inasmuch as some botanists, who are disposed to make the claim of priority override every other consideration in nomenclature, may assert that right for a supposed earlier name, *A. sanguinea*. But the *Pyrus sanguinea* of Pursh, the *Aronia sanguinea* of Nuttall, and the *Amelanchier sanguinea* of De Candolle and nearly all later authors, have no connection with this species. Roemer's name, based upon the *Mespilus Canadensis*, var. *oligocarpa*, of Michaux, who was the first to notice its peculiarities, must take precedence.

Plant Notes.

Two Interesting Willows.

THE Hoary Willow (*Salix candida*), a dwarf white shrub, two to five feet high, with narrow lanceolate leaves, densely covered, as well as the young shoots, with a white web-like wool, and with beautiful rose-colored catkins of flowers, is a rare plant in New England, where it is only known in one station in Essex County, Massachusetts, discovered a few years ago by Mr. John Robinson. Further south and west it is more common. This little Willow, although an inhabitant of bogs, is easily cultivated in ordinary garden soil. Its flowers and its foliage entitle it to a place in any garden.

Another interesting plant is *Salix balsamifera*. It was first discovered more than half a century ago among the White Mountains of New Hampshire; and later in British America, from Labrador to the Saskatchewan, by Drummond, Dr. Richardson, Bourgeau and Macoun. It was long unseen in the White Mountains, but in 1879 was rediscovered, and is now known in several places, thanks to the zeal of Mr. Edwin Faxon in exploring the White Mountain Flora. It is "a much and irregularly branched shrub, four to ten feet in height, sometimes growing in clumps of thickly-set, straight, upright stems one to two inches in diameter at the base, not much branched till near the top; bark of old stems rather smooth, dull gray, branches olive, recent twigs reddish-brown, or on the sunny side shining chestnut; leaves ovate, or ovate-lanceolate, two to three inches long, one to one and one-half inches wide, broadly rounded, and usually subcordate at base, acute or acuminate, at first very thin, sub-pellucid, and of a rich reddish color; at length rigid, dark green above, paler or glaucous beneath and beautifully reticulate veined, glabrous on both sides or with a few scattered silken hairs when just expanded; margin glandular-serrulate, petioles long and slender, stipules noticeably absent throughout, or on the most vigorous shoots minute and evanescent; aments borne on slender leafy peduncles; densely flowered, very silky, obtuse cylindrical, one to one and one-half inches long, scales rosy, anthers at first reddish, becoming deep yellow; female ament less silky, becoming very lax in fruit two inches or more long; capsules rostrate from a thick base, the conspicuously long and slender pedicels six to eight times the length of the nectary; style short, bifid, stigmas spreading, thick, two lobed." This description is taken from an interesting notice of this Willow in the May number of the Bulletin of the Torrey Botanical Club. It is from the pen of Mr. M. S. Bibb, to whom Mr. Edwin Faxon writes, "With just now the fertile capsules opening and coalescing into huge, soft balls of whitest wool, almost hiding the beautiful red and maroon leaves of the growing tips, it is certainly the handsomest Willow I ever saw."

Salix balsamifera takes kindly to cultivation and is now well established in the Arnold Arboretum.

7.

Pyrus salicifolia.—There is a remarkably fine specimen of the Willow-leaved Caucasian and Siberian Pear in the old nursery grounds of the Messrs. Parsons at Flushing. This plant, one of the hardiest and most ornamental of the family, is rarely seen in our gardens. It is a small tree, sometimes twenty or

twenty-five feet high, with spreading or pendulous branches, and narrow, silky hoary leaves, which make it a pleasing and conspicuous object throughout the season, while the white flowers, often tinged with pink, which appear rather later than those of the common Pear tree, are very beautiful. There is a variety with decidedly pendulous branches which is one of the most desirable of all the small weeping trees.

Cultural Department.

The Vegetable Garden.

OLD plants of Globe Artichokes produce heads about the 1st of July, and last in good bearing condition for several weeks; the plantations set out last spring, if from divided crowns, afford a succession, but if from this year's seedlings they may not bloom till next year. In order to keep them in good bearing condition, cut off all heads as soon as they are fit to use, even if they are not wanted for use. Among Jerusalem Artichokes pull out all shoots found outside of the hills; this gives larger tubers than when the plants are allowed to grow in a thicket. The tubers will not be large enough for use before September.

Asparagus beds should have a good cleaning and the plants should be left to grow at will. If the larvæ of the Asparagus beetle has appeared in the beds, in the morning when the plants are wet with dew dust them with Paris green and plaster of Paris in the same way and proportions as for Potato beetles on Potatoes, but be careful that no other vegetables, as Lettuce, Snap Beans or Cauliflowers, that may be grown near the Asparagus, are touched by the poison.

Sow Snap Beans at least once a week till the middle or end of August. They are, according to the weather, a seven to nine weeks' crop—from sowing till gathering. The Golden Wax varieties are considered the tenderest, but no yellow-fleshed Snap Bean looks as well upon the table as green-fleshed ones. Valentine and Mohawk, both green-fleshed sorts, are of first quality. If the vines of Lima Beans fall away from the poles tie them up. Keep them clean and well hoed to induce quick growth and early fruiting. The main crop generally comes from the 7th or 15th of August and continues in bearing condition till destroyed by frost. Try to keep up a supply of Peas till the Limas come, but this is sometimes hard to do, as after the middle of July mildew overtakes and destroys the Pea crop. About the middle of July to 1st of August put in a few sowings of Peas, to come in about the middle to end of September. Use early or second early Marrow Peas, as Alpha, McLean's Advancer, Veitch's Perfection, or Bliss' Abundance, and avoid late Peas, as Champion of England, Telephone and Omega, or round Peas, as Daniel O'Rourke. The American Wonder is a very good Pea in its way, dwarf habit, excellent flavor, but it does not bear enough or last long enough in usable condition to pay for growing it. Blue Beauty—a new Pea—has done exceptionally well this year. It was sown April 11th in well enriched sandy land, and we began picking the Peas June 20th. Vines two and one-half to three feet high, very prolific; pods round, compactly filled with large green peas, averaging five in a pod; peas of excellent flavor, and we continued to pick for six days. Another new Pea called Quantity, and which is after the fashion of Abundance, has also behaved very well. Sown April 11th, we began picking from it June 25th. Vines three to three and one-half feet high, very prolific; short, well-filled pods, containing five to six peas of capital flavor. The great English Pea of last year, Royal Jubilee, sown April 11th, fit to pick June 29th; has very large, flattish pods, containing some seven peas, large and of fine flavor. Vine three to four feet high. It is a fine, showy Pea, but not good enough to crowd out old favorites.

The Cabbage tribe now requires particular attention. We have had Wakefield Cabbage since the first of June, now Early Summer and All Seasons, but at this time of year when Peas and Cauliflower abound, Cabbage is not in much demand. Set out Cabbage and Savoys for fall and winter use. If transplanting is delayed they are not likely to form solid heads for pitting in winter. Plant out Brussels Sprouts as soon as possible; they should be in condition for use from September till Christmas. Of Cauliflower set out a main crop now, and again early in August. This last setting is to be lifted and heeled into cold-frames in November for use during the winter months. These plants like rich land. They usually follow early Sweet Corn, early Potatoes, Beans and Peas. But it often happens that we have not ground enough ready for them in July, and if we leave the plants in the seed beds they will get long-stemmed and overgrown, and when set out suffer

a good deal and take a long time to recover themselves. This can be avoided by lifting and potting the young plants at once. Use four or five inch pots, and plunge them to their brims and close together in an open plot out-of-doors. And if there is a probability of the plants being late, pot them off in this way, and it will help them greatly. When potted plants are set out they grow straight ahead without ever wilting. The earliest Cauliflower and Cabbage plants should be pot-raised; they should be almost half grown in pots before the land out-of-doors is fit to plant. Sow some Dwarf Green Curled Kale now for plants to set out in August. Any empty spaces can be filled with Kale. There is no need of its attaining mature size before winter; if even half grown it is very good. Before frosty weather sets in it may be lifted and heeled in close in a cold-frame for use during winter.

Sow a row or two of large-leaved (not large-rooted) Chicory for use for salads in winter. If sown much earlier it goes to seed.

The main crop of Carrots and Beets should not be sown before July. Carrots may be sown any time in July and a few the 1st of August. The short stump-rooted Carrots are better than the long ones. Carrots sown now keep tender all winter long, but Carrots raised from April and May sowings become so hard and flavorless before winter that they are only fit to feed to stock.

When to sow Beets must be regulated by the place and season. Here the proper time is late July and early August. Beets are only wanted just large enough, say two to three inches in diameter, for use, solid and tender. Large or early sown Beets are apt to be foggy inside and unfit for table use. And as it is with Beets so it is with Turnips. Winter Turnips should never be sown here before the middle of August, because they are hardier and have a longer season of growth, to the second or third week in November. Purple-top Round Globe and Strap-leaf Turnips are very good. Sow some Parsley now in a cold-frame for use in winter. That sown now will yield nice leaves from November till May or June, whereas the plants raised from spring sowings will run to flower after February.

Keep up a regular supply of Lettuces by frequent sowings and plantings. There is no Lettuce that will not run to seed very quickly at this time of year. Grow in rich soil and water abundantly in dry weather. But as this is a "quick" crop, use as a catch-crop between rows of other vegetables rather than as a main crop of themselves. In the same way make a small sowing of Spinach and Radishes every week. It is useless at this time of year to make large sowings or plantings of such short-lived crops as are Spinach, Lettuces or Radishes.

Keep up a succession of Sweet Corn. Moore's Concord gives excellent satisfaction, and a little may yet be planted every week.

Cut back Melon vines that wander beyond their proper place, and if they grow so thickly in the hills as to threaten to smother one another, do not hesitate to thin them out severely. Sow some Cucumbers in a cold-frame. Of course, if sown out-of-doors now, they will have time enough yet to mature their fruit before cold weather sets in, but about the end of August aphides usually attack and destroy the vines. In the open ground it is difficult to overcome this pest, but in frames they can be destroyed by a free use of fresh tobacco stems or powder, keeping the frames shut up at the same time.

Cucumbers for pickles are best grown in the open ground. For pickles, growers hereabout are very partial to Nichol's Medium Green.

Glen Cove, N. Y.

Wm. Falconer.

How to Grow Quinces.

MR. CHAS. L. JONES, of Newark, N. J., has had unvarying success with this fruit and his trees have now been in bearing thirteen years. For several years he has gathered from each tree from 400 to 450 Quinces, and last year the average was 475 to a tree. Mr. Jones asserts that any one can grow Quinces in a city back yard and he gives a full explanation of his method of culture in a recent number of the *Rural New Yorker*. The first injunction is not to stir the ground deeply near the tree. The Quince throws out many fine feeding roots near the surface, and these should be encouraged, fed and protected. Hence the ground about the tree, to a distance as far as its branches extend, is undisturbed, except to keep down the weeds, which are cut close to the surface with

a push-hoe. Late in autumn a dressing of barnyard manure is given, and in early summer a mulch of salt hay or other coarse material is added. This keeps the fine roots moist and cool and furnishes them with food.

The next essential is proper pruning. This does not mean an occasional thinning out of the branches as they become crowded. Indeed, as the tree is often deficient in foliage, no thinning out is practiced, but every spring the new growth all over the tree is pruned back or "headed in," so as to leave but four or five buds. This means that from two to four feet of wood is cut from every thrifty shoot. As a result of this treatment, the entire outer surface of the tree is literally covered with fruit of good size and quality.

It is a slow and tedious operation to pick off the young seed pods from Rhododendrons and Azaleas, but it pays to do it. If the pods are allowed to mature the new shoots which spring from lateral buds just below the terminal inflorescence often make a feeble and unsatisfactory growth, and fail to set flower

buds, the strength of the plant going to the perfection of the seeds. The operation, if performed as soon as the plants are out of flower and before the stem becomes hard, is quickly done by pinching out the whole flower cluster just above the new shoots, although some care is necessary not to remove these also. Of course, if the new growths are broken or mutilated, there will be no bloom on them the following year.

D.

Orchid Notes.

Orchids in Bloom at North Easton, Massachusetts.

THE collection of F. L. Ames, Esq., is worthy of note at this season, containing as it does handsome specimens, many of them unique. On entering the Orchid houses one passes through a handsome reception room, recently erected for the accommodation of visitors, into a large span-roofed structure 100 feet long containing chiefly Cypripediums and Cattleyas. A few days ago the former were remarkably gay. Worthy of note among them was a handsome plant of the rare *C. Schroderae* with six stout spikes bearing ten large, well formed flowers, a sight not easily forgotten. Among other well grown and healthy plants were examples of *C. caudatum Wallisii*,

Fig. 41.—Amelanchier oligocarpa.—See page 245.

sometimes called the white *C. caudatum*, with twelve strong growths and four fine flowers, the tails measuring fully twenty-one inches, of *C. Veitchii* with seven bold flowers, and an exceptionally fine variety, *C. præstans*, with enormous flowers and broad foliage of stout leathery texture; of *C. ananthum*, a grand specimen, promising a fine display of bloom; of *C. Arthurianum*, with eleven strong growths, together with five plants of *C. Arnesianum*, *C. albopurpureum*, *C. Fairieanum*, *C. tonsum*, *C. Druryi*, *C. Sedeni candidulum*, *C. Petri*, *C. selligerum majus*, *C. Morganæ*, and numerous other rare species. The Cattleyas were showing a marked improvement, the foliage having a dark green appearance, and quantities of newly made roots were spreading over the pots and baskets in all directions. Mr. Robinson, the gardener, attributes this to the abundant supply of air he gives the plants, the atmosphere in the house being always fresh and invigorating, a point he considers essential if strong growths and well formed flowers are to be expected. Several specimens in grand condition were noted, amongst them a plant in full bloom and with 100 bulbs of the rare *Cattleya Wagnerii*, the showy *C. Reineckiana* with twelve flowers and in fine form, also two magnificent specimens in full bloom with upwards of 200 bulbs of *Cattleya Skinneri*. The rare *C. Triana Lecana*, *C. Trianae Osmanii*, *Lalia bella*, *L. Perrinii alba*, *L. callistoglossa*, *L. grandis*, with large specimens of *L. purpurata*, *L. elegans* and *L. elegans alba*, are all in superb condition. One of the finest examples in cultivation of *Sobralia xantholeuca* was in bloom, its large yellow flowers affording a delightful contrast with its dark green foliage. With the Cattleyas were noticed a handsome plant of the scarce *Calogync Dayana* with six fine spikes, a specimen of *Dendrochilum glumaceum*, and a striking variety of *Calanthe masuca*, the mauve color of its flowers being unusually dark. The Pleiones occupy a shady position of the same house, where they receive an abundant supply of water during growth. Thunias also were in fine health. The rare *T. Veitchii*, a hybrid between *T. Bensoniæ* and *T. Marshalli*, is in bloom and very attractive, certainly a splendid acquisition to this desirable genus. The Vandas and *Ærides* in this collection grow very rapidly, and among the former are specimens of *Vanda Sanderiana*, *V. carulea*, *V. Lowii*, *V. suavis*, *V. tricolor*, and the recently introduced *V. Amesiana*. *Ærides Leonii expansum* (in bloom), *A. odoratum*, *A. Fieldingi*, *A. crassifolium* and others were represented by fine specimens. Many hybrid Odontoglosses of the Alexandræ type were growing freely in the house set apart for this genus, also large plants of *Oncidium macranthum* with stout growths, and a fine healthy group of *Masdevallias* growing rapidly, including amongst others a fine plant of the rare *Masdevallia Carderi*, with examples of *M. Fraseri*, a hybrid between *M. ignea* and *M. Harryana*, strong plants of *M. Schlimii*, *M. Veitchii*, and several plants of the curious and interesting *M. Chimara*.

June 20th.

A. D.

Odontoglossum nebulosum.—This is a pretty Mexican Orchid belonging to the maculatum group, with round, compressed bulbs, and short, broadly lanceolate leaves. The scapes which spring from the young growths are erect, about 10 inches long, and bear six to eight flowers. These are about three inches across, pure white, with the whole central portion spotted with greenish brown shaded to a red brown on the outer circles. The crest is yellow and column white. There is a variety called *candidissima* in which the spots are absent. *O. pardinum*, a species spotted more thickly than the average, has been long introduced, but does not seem to be very popular for some cause. It is easy to grow, requiring the same treatment as *O. crispum*, except that it needs a longer rest and much less water during this period. *Odontoglossum Walisii purum* is quite distinct. In growth it resembles *O. roseum*, but has rounder and larger bulbs and longer leaves. The raceme is slender, drooping, and bears some twelve flowers. These are about two inches across, not unlike a good variety of *O. Sanderianum*. The pandurate lip is beautifully fringed, rose purple, bordered with white. It is a native of the mountains of Venezuela and grows well with the treatment required by the other species.

Cypripedium Parishii, a striking species with leathery, dark green leaves. The stout, hairy scape bears three to six flowers. The sepals are pale green or straw color. Petals four to six inches long, drooping, narrow, and very much twisted, vinous purple in color. The lip is green, stained with purple. This species is not so amenable to cultivation as most of the genus, doing best here in light potting material with plenty of heat and water.

Dendrobium chrysoloxum suavissimum.—This flowers

much later than the type and differs from it in having a dark maroon blotch in centre of the golden yellow flower. It produces many flowered racemes from the top of the clavate, deeply furrowed bulbs, and will continue flowering from the old bulbs for many years. It makes a grand plant for decorative purposes and is very useful for cut flowers. Coming from the hot plains of Burmah, it requires considerable heat to make good bulbs. These must be thoroughly ripened by exposure to sunlight and air, taking care not to burn the leaves during the resting season. Only enough water should be given to keep the bulbs from shriveling.

Angræcum falcatum.—This is a small, compact Orchid, with narrow dark green leaves about three inches long, from the axils of which are produced many flowered spikes of pure white fragrant flowers, with a spur about three inches long also white. *A. densum* may only be a variety of this. The leaves are shorter, broader and more erect. The flowers are white, as in *A. falcatum*, but with much shorter spurs. These two kinds are native of Japan and are generally supposed to require a cool house, but they are doing well here in the East India house.

F. Goldring.

Notes from the Arnold Arboretum.

BY far the most beautiful of the American *Andromedas* is *A. speciosa*. It is a native of the coast country from North Carolina to Florida, where it is found along the borders of the Pine-barren ponds, and, in spite of its southern origin, is perfectly hardy and at home here. It is a low shrub, never more than three or four feet high, with bright green foliage, which, in one variety (var. *pulverulenta*), is chalky-white, with a dense glaucous bloom. The flowers are pure white, a third of an inch deep by as much wide when expanded, and appear in large racemed fascicles, on naked branches of the preceding year. This charming plant has been in cultivation since the beginning of the century, and once was a great favorite in English gardens. In this country it is rarely met with in cultivation, in spite of its many attractions. It is now blooming copiously.

Not less attractive in its way is *Philadelphus microphyllus*, the smallest of the family, and a native of the mountains of southern Colorado and New Mexico, whence it was introduced into cultivation by the Arboretum a few years ago. It is a twiggy shrub, with slender stems two or three feet tall, with broadly ovate, hairy leaves, half an inch long, dark green and shining above, pale below, and small white, deliciously fragrant flowers, which no one who has ever climbed over the cliffs above the Grand Cañon of the Arkansas in the early days of July, will ever forget. *Philadelphus microphyllus* is perfectly hardy here, and an excellent little shrub for the rock-garden. The earliest *Ceanothus* to flower here (where none of the handsome California species are hardy), and ten or twelve days earlier than the common New Jersey Tea (*C. Americanus*), is *C. ovalis*. It is a common western species, only just reaching New England on the eastern shores of Lake Champlain, and probably very rarely cultivated, in spite of the fact that it is a useful low shrub, two or three feet high, of compact habit, good foliage, and handsome, white flowers, which come later than those of most shrubs—a valuable quality.

It is the habit of late and continuous blooming through the summer which gives value to the Allsaints Cherry, a European plant of very uncertain origin. It is a handsome dwarf tree, with long, pendulous branches. In nurseries it is generally grafted standard high on the common Cherry, when the branches soon sweep the ground. It produces through the season large, white, solitary flowers, on long, drooping stems, ripe fruit and flowers appearing on the tree at the same time. The Allsaints Cherry makes a very pretty specimen for a small lawn or garden. It is very rarely seen in this country.

Acanthopanax spinosum (*Aralia pentaphylla*) is now in flower. It is a very hardy Japanese shrub, which attains a height here of eight or ten feet, with wide spreading, arching, pale gray branches, armed with stout, solitary prickles, and covered with bright green, shining, five-parted leaves, five or six inches across, and borne on long clustered petioles. The small green flowers, in axillary, long-stemmed umbels, are not showy, and the value of this plant lies in its graceful habit and handsome and abundant foliage. It is an excellent subject to plant on a rocky bank.

Rosa repens is probably a form of the common and widely distributed European Field Rose (*R. arvensis*), although abundantly distinct for garden purposes. It has trailing, prostrate branches, eight or ten feet long, handsome dark

green foliage, and small, pure white, single flowers, solitary or two or three together. It continues to expand its flowers during several weeks and is one of the most attractive of the foreign Roses in the collection. It is well suited to plant on banks or among other shrubs, where it can send its long stems freely over them, or it is an exceedingly attractive plant when trained to a tall stake or to a pillar.

Many of the American Greenbriers (*Smilax*) are handsome climbing plants. They are never cultivated, however, although some of the strong growing species can be made to serve a good purpose in preventing access across the boundaries of parks or pleasure grounds. Neither man nor beast will try to break through a well-grown mass of the tough, horribly armed stems of the common Greenbrier, or Bullbrier (*Smilax rotundifolia*), one of the handsomest plants in leaf found in the Atlantic forests.

Another species peculiar to the south, *S. Pseudo-China*, is blooming here now, and although its stems are unarmed, or nearly so, they are so tough and become so interlaced, that passage through them is almost impossible. It soon spreads from the tuberous root-stocks, sending up stems ten or twelve feet long, covered with large, dark green, ovate-oblong, sharply pointed leaves, the small clusters of greenish flowers and handsome black fruit on slender stems three or four times longer than the petioles. There are still several species of these interesting plants to introduce into cultivation and much to be learned of their horticultural capabilities.

Several of the Viburnums and Dogwoods of the Northern States are now in flower. Among them are shrubs which are unsurpassed in beauty of foliage, or of flowers, or of fruit. They can all be easily cultivated and all thrive in any variety of soil and in all exposures. Where great masses of low foliage is needed in public parks, or where shrubberies are liable to suffer from neglect, as in city squares, or on railroad embankments, or where the adornment of country roadsides is undertaken, these and other native shrubs should be selected for the purpose, rather than exotic garden plants, which always require considerable attention to keep them in good order, and which, often fastidious about soil, are liable to be attacked by insect and fungoid enemies. Our common native shrubs, however, are very rarely cultivated. A few years ago they were completely unknown in nurseries and entirely neglected by planters. Some attention has been drawn to them lately, but they are still rare in nurseries, and it is impossible to obtain them in large quantities. Such plants are easily and quickly raised, and a demand for them will soon create a supply. Attention has already been directed, in an earlier issue of these notes, to the beauty of *Viburnum Lentago*. Among the species in bloom a few days later are *Viburnum dentatum*, the Arrow-wood, a compact shrub, with erect branches eight or ten feet high, ample, sharply toothed and strongly veined leaves, and broad, peduncled cymes of white flowers, which in the early autumn are followed by bright blue, handsome fruit. *Viburnum cassinoides* grows six to ten feet high, in the northern swamps, which are its home. It has handsome, leathery, opaque, or dull, ovate, generally entire leaves, and broad, flat cymes of yellow-white flowers. This is one of the handsomest shrubs in the Northern States. It is easily cultivated, and soon grows into a round-topped, spreading specimen, flowering with the greatest profusion. *Viburnum acerifolium* is a smaller plant than either of those already mentioned, rarely exceeding a height of three or four feet on the rocky wooded hillsides where it abounds in the northern States. It is a plant of compact habit, producing freely small, long-stemmed clusters of white flowers, but its greatest beauty is in the rich, deep claret color which its handsome, three-lobed leaves assume late in autumn.

Among the native Dogwoods now in flower the handsomest, perhaps, are *C. alternifolia*, a shrub-like tree with wide spreading branches and a flat top, the alternate leaves crowded toward the ends of the branchlets, and open, wide cymes of pale yellow or white flowers, followed by deep blue fruit, with reddish stalks; and *C. circinata*, the round-leaved Cornel, a compact shrub six to ten feet high, with green, warty-dotted branches, large, round-oval, pale green leaves, four or five inches across, woolly on the lower side, flat cymes of rather large flowers, and light blue fruit. This is certainly one of the most attractive of all the Cornels.

Cornus paniculata, the Panicked Cornel, a tall, spreading shrub, often ten or twelve feet high, with smooth, gray branches, taper pointed, ovate-lanceolate leaves, and cymes or panicles of pure white flowers, which are produced in the greatest profusion, and quite cover the plant at this season. The handsome fruit is white. This is a very common and widely distributed northern plant found along the borders

of streams and abounding on the margins of lowland woods and thickets. No shrub is more easily cultivated, and none is better suited to grace a park-plantation in the Northern States; *Cornus stolonifera*, the Red Osier, with its bright, red-purple, annual shoots, and long, pale foliage, is a useful plant for general planting. The flowers are pale yellow, produced in small, flat cymes, and have the merit of appearing later than those of most of the Dogwoods. The fruit is whitish or lead color. It is a very common northern shrub, found in the wet borders of swamps and in low woods. The habit of this plant of spreading by prostrate or subterranean shoots, and thus quickly forming broad clumps, which sometimes reach a height of six feet, makes it a useful plant for covering rapidly the ground among trees or larger growing shrubs, while its brilliantly colored branches add interest and variety to a plantation in winter. But by far the handsomest native shrub now in flower is the common Elder (*Sambucus Canadensis*). It is such a familiar object in every northern landscape that few persons realize that the Elder possesses all the qualifications of an ornamental plant of the very first class—hardiness, vigorous and rapid growth, good habit, pleasing foliage, handsome and conspicuous fragrant flowers, opening at a time when nearly all trees and shrubs have passed the blooming period; and fruit even handsomer and more conspicuous than the flowers which precede it. Few plants are better worth cultivating in a large garden or park, and yet, with the exception of the ugly yellow-leaved variety, it is seldom cultivated; and most gardeners of the modern school would consider it a weed to be exterminated if, by chance, it should spring up along fence lines, where birds often sow it, and where, if the ground is moist, it soon forms splendid masses of shrubbery. There is a form with deeply cut leaves which will interest persons fond of novelties, or of plants of peculiar or abnormal growth.

The very latest of the Thorns to bloom here is an American species, the so-called Washington Thorn (*Crataegus cordata*), now in full flower. It is a handsome small tree, sometimes twenty-five feet high, and perfectly hardy here, although it is a southern plant, not found growing spontaneously north of Virginia and Kentucky. In the mountainous parts of these states and of those further south it is a common inhabitant of rich woods. It has brightly shining, broadly ovate or triangular, deeply cleft, serrate leaves, on long, slender petioles, rather small flowers in simple corymbs, and small, but very showy, bright scarlet fruit, which hangs until the early winter. The autumnal coloring of the foliage, which does not change until very late, is brilliant and beautiful. *Crataegus cordata* is one of the most distinct of the American Thorns, and one of the best small trees which can be planted in Northern gardens and shrubberies. It blooms only a few days later than *Crataegus tomentosa*, an Alleghanian and western species, which must not be confounded with some of the pubescent forms of *C. coccinea*, to which many recent writers upon American botany have improperly referred this Linnean species, which does not occur in the Northern and Eastern States east of western New York. *C. tomentosa* may be readily distinguished from any of the forms of *C. coccinea*, not only by the fact that it flowers many weeks later, but by the pale gray branches, almost entirely destitute of thorns, by its thicker and more pubescent leaves, without glands, gradually contracted into a stout, margined petiole, and densely pubescent on the under side, as are the calyx and stems of the inflorescence. It may be distinguished, too, from forms of *C. coccinea* by its broader and looser corymbs, and by the extremely disagreeable odor of the flowers, and by the smaller, oblong, upright fruit, which does not ripen until long after that of *C. coccinea* has fallen to the ground. *C. tomentosa* is perfectly hardy, making in cultivation a small, handsome tree, with spreading branches and rather a flat top. The orange tints which its leaves assume in late autumn are attractive.

It is hopeless to undertake to unravel the confused synonymy of the multitude of garden forms of *Philadelphus*, or even to refer them to wild types, so mixed has been the blood of the different species through years of cultivation, and so unstable are many of the characters depended on to separate the different species. It is well to record, however, that the earliest to flower in the collection, by ten or twelve days, is the Manchurian and Japanese plant known as *P. Schrenkii*, and now considered by Maximowicz as one of the varieties (var. *Satsumi*) of the very variable and widely distributed *P. coronaria*, the common Syringa of gardens. By far the handsomest of the early flowering Syringas in the collection, however, is that known in gardens as *P. speciosus*. It is a tall, erect growing plant, covered with large, pure white flowers, and evidently a hybrid or a variety of the American *P. grandiflorus*.

The Forest.

Notes on the Longevity of Coniferous Tree Seeds.

LOUDON says European Larch seeds will not germinate after they have been a few months out of the cones. Our experience proves that they will germinate perfectly well eighteen months, and passably well thirty months, after leaving the cones. The belief seems to be general that White Pine seeds become rancid and will not germinate after the first season. Our experience proves that they will germinate thirty months after leaving the cones.

I think further experience will prove that the seeds of Colorado Conifers, and seeds of coniferous trees in all dry climates, will preserve their vitality still longer. We had a sack of *Pinus ponderosa* seeds from which we sowed five years in succession, and, to all appearance, they germinated the fifth year as freely as the first. Seeds of *Picea pungens* and *Pseudotsuga Douglasii* have germinated with us, apparently, as well the third year as the first. I regret that we had not seeds to try the experiment longer.

Practice has changed wonderfully during the last half century in this direction, and now, instead of keeping seeds in the cones, they are taken out as soon as the cones are gathered and dried, yet some writers on forest subjects still recommend keeping the seeds in the cones till time for sowing. But how can Fir seeds be kept in the cones? The cones fall in pieces as soon as the seeds ripen. They will hold together, it is true, if collected before the seeds are ripe, but in that case the cones will become mouldy and injure the seeds. There may be a few species of Pines which will keep longer in the cones than out, such as *Pinus Banksiana*, *P. contorta* and *P. tuberculata*, which hold the hard, dry cones on the trees for many years; but these are kinds which are seldom, if ever, used, and of little value. The White, and many other Pines, the Spruces and Arbor-vitæ, hold the cones on the trees for a short time after the seeds have ripened, but they shed all the seeds as soon as they are ripe, in August, September and October. I do not see how the seeds can be benefited by being left in the cones after they have ripened, nor how they can be kept as safely in cones as in bags.

It is fortunate for the forestry of this country that seeds of forest trees can be kept for years in this manner, otherwise a succession of plants could not well be kept up, for forest trees do not produce seeds every year, even when the seasons are favorable. In the year 1884 I scanned the White Pine trees closely from the head of Lake Michigan to the New England coast, thence from Rhode Island north to the Canada line, thence through the Adirondack Mountains, along the Black River, and into the White Pine regions in Pennsylvania, and saw no trees producing cones. We then sent a collector up into northern Wisconsin and the Michigan peninsula, but he found that the trees were not producing seeds. It is often the case that when forest trees fail to produce seeds in one part of the country they are abundant in another locality; but in this case the only exceptions I heard of were one locality in the Lower Provinces of Canada, and the cultivated trees west of Lake Michigan. What is true of the White Pine is measurably true of all other forest trees, and now, when so much is written on the subject of forestry, it is surprising that so little is written on this branch of the subject. Even if the seasons are all favorable one can hardly expect a crop of White Pine seeds oftener than once in three years. One year is needed for the blooming of the male and female flowers and the fertilizing of the embryo cones, the next year for the growth of the cones and the perfecting of the seeds, which draws so heavily on the vitality of the trees that they require the third year to recuperate and form blossom buds to continue the blossoming the year following. Wherever I had an opportunity to examine, as in New England, on the Adirondacks, and in the Pine belt in

Pennsylvania, I found the trees all well set with embryo cones, and our collector reported the same for the region south of Lake Superior, and as these embryo cones were already fertilized we were certain of a crop of seeds the next autumn. Of course new seeds are safer and better than old seeds, and will germinate quicker. We make it a rule to sow old seeds thicker than new, and either to sow them earlier or soften them by soaking before we sow them. Robert Douglas.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—I have been starting a small plantation of forest trees and meet various difficulties. I would like some of your practical correspondents to let me know how seedlings are introduced into large plantations. White Ash, for instance, reaches the ground in the spring and is about the size of a knitting-needle, Box Elder, Elm, Mulberry the same, Cottonwood only a little larger. Do planters trust fifty acres of these set four feet apart to horse cultivators with ordinary drivers? I have hard work to get a man who can see them when working with a hoe. Are the prairies free from weeds? Are large plantations of nuts made in the fall of the year or of acorns?

I have tried a few acres, but find the nuts are so late to sprout that the weeds hide them, and am almost tempted to plow the whole ground early in the spring and cultivate it to get rid of weeds, and expect that the nuts not having started will be none the worse; otherwise keep the nuts in a pile till spring. I find Ash and a good many other seeds very hard to get started; hardly one planted last fall or early this spring is yet showing this second of June. Ash, Maple and Cherry seeds in the ground since last spring were up a week ago. Perhaps other readers will be interested in a reply.

Norwood, Ontario.

G. M. Grover.

[White Ash, Box Elder or Elm seedlings the size of knitting-needles are too small and weak for forest planting. One year old first-class seedlings of Ash or Box Elder should be the size of a lead pencil or larger, while second-class seedlings of the same age sold in nurseries at about half the price of first-class seedlings, although generally considered too delicate for general planting, should be at least three times the diameter of a knitting-needle. White Elm seedlings one year old reach a height of from twelve to twenty-four inches the first season, but are more slender than Ash or Box Elder in proportion to height. It has been demonstrated by Mr. Robert Douglas, who has successfully planted and grown more than a thousand acres of forest trees in the rich prairie soil of southern Kansas, and by other tree growers, that one year old seedling trees can be planted and kept free of weeds with horse cultivators in the hands of ordinary laborers. In Mr. Douglas' plantations, except in the case of a few acres, no cultivating whatever has been done by hand. The secret of success in forest planting of this sort is to get the sod thoroughly rotted before the trees are set, to use only strong, well selected plants, and to keep the weeds under from the start. If the young trees once get smothered in a growth of tall perennial prairie weeds the case is hopeless, and there is nothing to do but to plow the whole plantation up and make a new one. It is practically impossible to raise a forest on rich arable land by planting acorns or nuts where the trees are to stand. Grasses and weeds will smother the seedlings as they appear, or will so hide them that it will be out of the question to cultivate the field without destroying the trees. Nuts can only be planted successfully, in this country of vigorous weeds, in light sod land where the growth of the grass will not overtop the young trees, or among other trees which partially shade the ground and prevent the growth of weeds. If a forest of Oaks or Walnuts is to be raised on prairie or other rich land, yearling or two-year-old transplanted seedlings should be set and thoroughly cultivated until they shade the ground and prevent the growth of weeds. In an article printed in Number 2 of GARDEN AND FOREST, Mr. Douglas gives practical directions for raising different forest trees from seed.—Ed.]

Hardy Fruit Trees.

To the Editor of GARDEN AND FOREST:

Sir.—Under this heading I have read with care the suggestive paper, by Mr. F. W. Burbidge, in the *Gardeners' Chronicle*, and the editorial notes on it in GARDEN AND FOREST. The articles are timely and well meant, but the whole facts as to the character of the fruits of the Volga, and their singular capacity for adapting themselves to exceedingly varied climates, are not given.

As to the size, beauty and quality of the Apples of the Volga from Kazan to Sarepta—a distance by the river of near one thousand miles—I will only say that they will surprise the horticultural tourist who examines and tests them as we did in the autumn of 1882. If we were confined alone to the many varieties of the Oldenburg, Apont and Skanka families they would give a list difficult to equal in England, though in quality they are far excelled in the United States.

As to their adaptation to varied climates a few examples may be profitably considered. Taking up the latest edition of Hogg's *Fruit Manual*, we find that ten varieties of the Russian Apples, several of them from the Volga, are declared to be perfectly satisfactory in tree, foliage, habits of bearing and character of fruit in England—viz., Borovitsky, Sugar Loaf Pippin, Alexander, Constantine, Peach, Malakovna, Red Transparent, Red Astrachan, Court Penduplat, White Astrachan and Muscovy. Again, at Pomona, in south California, I found five varieties of Russian Apples—some of them from the Volga—perfect in tree, foliage and fruit, standing among, so-called, American sorts that were dwarfed and scrubby in tree, and imperfect in foliage and fruit. Their thick foliage and pubescent fruit seemed to perfectly fit them to endure the great summer heat and the great changes in temperature of the day and night. In the upper valleys of California we also find the Sweet Anis of the Volga—perfect in tree and fruit—growing beside the Orange and the Fig.

Still again, so far as tried, the Russian Apples, Pears and Cherries stand the summer heat of Alabama, Florida and Texas better than any other varieties except those of China.

To all this we must add that, next to the Siberian Crabs, the Apples of the Volga endure the trying summers and winters of Minnesota, north Dakota, and even Manitoba, most perfectly.

J. L. Budd.
